ALPES-MARITIMES, a S. E. department of France, formed from the circle of Nice, ceded to France by Italy in 1860, and the arrondissement of Grasse, taken from the department of Var; area 1,482 sq. m.; pop. in 1872, 199,037. It lies between the Mediterranean and the mountains from which it takes its name, and is watered by the Var and several smaller streams. The surface is mountainous and crossed by numerous valleys. The climate is the finest in France. The country near the coast is well cultivated, and elsewhere there are valuable forests and various mineral productions. The department is divided into the arrondissements of Nice, Grasse, and Puget-Théniers. The coast is dotted with places naturally or historically interesting, such as Nice, the capital, Cannes, Antibes, and Mentone.

ALPHA AND OMEGA, the first and last letters of the Greek alphabet. The book of Revelation three times designates Jesus Christ by the title Alpha and Omega, perhaps in imitation of Isaiah (xliv. 6), who represents God as saying, "I am the first, and I am the last."

ALPHABET (from the names of the first two Greek letters, *alpha* and *beta*, and therefore the equivalent of our A, B, C), the scheme of signs by which a language is written; as also, less properly, the scheme of articulate sounds expressed by those signs, and constituting by their combinations the spoken language. It is in the former sense only that the word will be understood here; the scheme of articulations—the spoken alphabet, as it may be termed—will be treated, in its character and relations, under the head of *PHONETICS*. All alphabets are not of the same kind. The intent of such a one as the Greek, the Latin, and our own, is to furnish a sign for every articulate sound of the spoken language, whether vowel or consonant; and its ideal is realized when there are practically just as many written characters as sounds, and each has its own unvarying value, so that the written language is an accurate and unambiguous reflection of the spoken. This state of things is not wont to prevail continuously in any given language; for, in the history of a literary language, the words change their mode of utterance, or their spoken form, while their mode of spelling, or their written form, remains unaltered, or is not correspondingly altered; so that the spelling comes to be "historical" in-

stead of "phonetic," or to represent former instead of present pronunciation. Such is, to a certain extent, the character of our English spelling; but very incompletely and irregularly, and with intermixture of arbitrariness, and even blunders, of every kind; it is an evil that is tolerated, and by many even clung to and extolled, because it is familiar, and a reform would be attended with great difficulties, and productive for a time of yet greater inconvenience.—Some alphabets are syllabic; that is to say, they have a sign for every syllable, composed of a vowel or diphthong and one or more consonants, that enters into the composition of the words of a language: examples are the Cherokee syllabary, invented by Sequoyah or George Gness, containing 85 signs; and the Japanese *iroha*, containing 47 signs. Others, again, are consonantal; that is to say, the consonants are either written alone, the vowels being unexpressed, or only the consonant has a full sign, and the vowel is expressed by a modification of it, or a subsidiary sign attached to it: examples are the Hebrew and Sanskrit alphabets, each having a large number of kindred systems. Then there are modes of writing which are not entitled to be called alphabetic: as the Egyptian or hieroglyphic, in which simple phonetic or alphabetic signs are mingled with syllabic, ideographic, and pictorial; or as the Chinese, in which there is an indivisible sign for each whole (monosyllabic) word, and even to a great extent for each different meaning of a word, so that the written signs are many times more numerous than the spoken words. The origin and historical and theoretic relations of these different modes of representing to the eye the spoken word will be explained in the article *WRITING*.—The English alphabet is derived from the Latin, the Latin from the Greek, and the Greek from the Phœnician. The origin of the Greek alphabet is reported by the Greeks themselves; and their report is confirmed both by the forms of their characters, and by the names given them: *alpha*, *beta*, *gamma*, *delta*, &c., are the Hebrew *aleph*, *beth*, *gimel*, *daleth*, &c.—appellations which have their correspondents also in the other Semitic alphabets, as the Syriac and Arabic. The Phœnician alphabet, in fact, is the old Semitic alphabet, used by many of the Semitic peoples; itself of unknown origin, it has become the mother of nearly all the prevailing modes of writing in the world. It was a consonantal scheme, composed of 22 signs (see the table on p. 351), representing the following sounds: ' (*aleph*), *b*, *g*, *d*, *h*, *v*, *z*, ' *h*, *t*, *y*, *k*, *l*, *m*, *n*, *s*, } (*ain*), *p*, *g*, *r*, *sh*, *t*. Of these, *aleph* is rather a theoretical device, a figment to attach the utterance of any desired vowel to; ' *h* is a stronger and deeper *h*; *l* and *g* are different from our ordinary *t* and *s*, as being spoken with greater effort, and with a peculiar articulation (the flat of the tongue, it is said, pressed against the roof of the mouth); *ain* is a very peculiar guttural utterance, wholly unlike anything in

our system of sounds. The Greeks took from this scheme, without important change of value, the signs for *b, g, d, w, h, k, l, m, n, p, q, r, t*; others they altered in sound, converting ξ into the sign for aspirated *t* (*th*, or *theta*), ζ and σ into signs for double consonants, *ds* (or *zeta*) and *ks* (or *xi*); while they used ξ and σ for a time interchangeably as signs for their single sibilant, until the former finally went out of use. But the most important modification carried out by the Greeks was that by which they obtained signs for vowels also: *aleph, h*, and *ain*, as being useless to them, they made into *a, e* (*epsilon*), and *o* (*omicron*); *y* (*god*) was turned into *i* (*iotu*); and for *u* was invented a new sign, *upsilon*, shaped like our *V* or *Y* (the two forms being used at first indifferently). This modification converted the alphabet from a consonantal into one purely and completely phonetic, a perfect instrument of the expression of spoken language. Other additions were of somewhat later date: signs for the aspirate labial (*ph*, or *phi*) and guttural (*kh*, or *chi*) as parallel with the *th* or *theta*, and for the assibilated labial (*ps*, or *psi*) as parallel with the *ds* or *zeta* and *ks* or *xi*, were invented and appended at the end of the scheme; a sign for long \bar{o} (*omega*) was further added, and *H*, which had signified the rough breathing or aspiration, was altered in value to a long \bar{e} (*eta*). Moreover, the *w* or "digamma" went by degrees entirely out of use, as did also the *q* or "koppa," and the two were retained only as numeral signs. Thus the constitution of the Greek alphabet, as we know it, is in all its parts accounted for. The additions and changes went on by degrees, and differently in different parts and colonies of Greece; the final form is that given by the Ionians of Asia Minor, and adopted throughout the whole of Greece about 400 B. C. The Semitic original was always written from right to left; the earliest Greek was written either way, or in different directions in alternate lines (the characters being made to face the other way when written from left to right); finally, the present method became established in universal use.—The form of Greek alphabet from which is derived the Latin was not that one which, as above described, was finally adopted throughout Greece, but differed from it in sundry particulars: the *H* still had its *h* value; the *Q* was still used, and was retained by the Latins for writing the *k* sound followed by *u* before another vowel; the character for *w*, or the *digamma*, was also in use, and was applied to represent the (as labial, somewhat kindred) sound *f*, for which the Greek had no sign; and *X* (as generally on the mainland of Greece and in her western colonies) had the value of *ks*, not of *ch*. The earliest Latin alphabet, then, was *A, B, C* (pronounced as *g*), *D, E, F, Z, H, I, K, L, M, N, O, P, Q, R, S, T, V, X*, 21 letters. *A, Z* is found in the earliest monuments, but speedily went out of use, and was about the time of Cicero reintroduced as a foreigner, along with

Y (originally the same sign with *V*, but having now become fixed in Greek usage in this form, and having taken a new value, that of the French *u* or German \ddot{u}), in order to write in Greek words the peculiar Greek sounds of those letters. A very peculiar change in the constitution of the Latin alphabet was made in connection with *C, K*, and *G*. The *K* passed out of customary use about the time of the decemvirs, and was employed only in a small number of words (with occasional occurrence in others), while *C*, the equivalent of the Greek *gamma*, and originally having the same value, was employed to write both the *g* and *k* sounds—doubtless because these two sounds were in the popular utterance only imperfectly distinguished from one another. And when later (about 300 B. C.), under Greek influence, the careful distinction of the two sounds in writing was resumed, instead of giving *C* its old value and restoring *K* to common use, the Romans very strangely continued to the former its *k* value, and made from it by a slight alteration a new sign, *G*, for the *g* value. The final Latin scheme, after the addition of *Y* and *Z*, thus consisted of 23 signs. In it *I* and *J* were not distinguished, nor *U* and *V*; *J* and *U* are merely graphic variations of *I* and *V*, and of the same value with the latter; the Romans did not regard the vowel and semivowel values of these two sounds—*i* (that is, *i* in *pique*, or "long *e*," as we call it) and *y* on the one side, *u* (that is, *u* in *rule*, or the long sound of double *o* in *fool*) and *w* on the other—as being sufficiently diverse to need a double designation.—The chief alteration, now, that the Latin alphabet has undergone in being adapted to English use is the establishment of *J* and *U* as independent letters with distinct values, by the side of *I* and *V*; *J* having for its peculiar sound (nearly a compound of *d* with *zh*, or with the *z* sound of *azure*) into which the Latin *J* or *y* sound has been usually converted, and *V* being applied to represent the sound into which, in most of the literary languages of modern Europe (as in the later Latin also), the original *w* sound has passed. And then, as final extension, we have, in common with some other European languages, added a "double *U*"—*i. e.*, *VV* or *W*—to represent the *u* semivowel, or *w* sound: this character is of a date no more ancient than the middle ages. By all these various reductions and additions, our alphabet has grown from the original 22 signs of the Phœnician to the present scheme of 26 signs; which, by way of summary, we may distribute into eight classes, as follows: 1, letters inherited from the Phœnicians, and still bearing nearly their Phœnician value, are twelve, namely, *B, D, H, K, L, M, N, P, Q, R, S, T*; 2, letters originally Phœnician, but having their value changed by the Greeks (in every case but one from consonant to vowel), are five, namely, *A, E, I, O, Z*; 3, additional letters invented by the Greeks are two, namely, *U* (= *V* or *Y*), *X*; 4, Phœnician letters entering into

the Latin alphabet with changed value are two, namely, C, F; 5, of Latin invention is a single letter, G; 6, imported from Greek into Latin in differentiated form and with later Greek value is one, Y; 7, varying graphic forms of Latin letters, raised in modern times to independent value, are two, J, V; 8, recent addition, made by doubling an old sign, is one letter, W. If we had shown, in the handling of the system of signs received from abroad, the same freedom and independence as the Greeks and Romans, we should have an alphabet of at least 32 letters, instead of 26; for we require separate representatives for the vowel sound in *eat* and *care*, for that in *what* and *all*, and for that in *but* and *burn*; and for the sibilants in *shun* and *azure*, the initial spirants of *thin* and *this*, and the nasal in *singing*; while the *ch* sound in *church* is also, though strictly of compound nature, well entitled to a separate character: the C, Q, and X, on the other hand, having no value which should render their retention necessary.—The ground of the arrangement of our alphabet is in the main inferrible from the account of its history given above, being, when once started from the Phœnician basis, strictly a historical one: A to F follow the Phœnician order; G was put by the Romans in the place of the consciously omitted Z; H and I, again, have their Phœnician positions; J follows the letter of which it is, as it were, the recently separated shadow; K to T, again, are in their Phœnician places; U comes next, as being the first addition made by the Greeks, and it is succeeded by V and W, as I by J; X is another Greek addition, adopted into the earliest Roman alphabet; Y and Z are the later additions made to the Latin from the Greek. When, however, we come to inquire into the reason for the Phœnician order itself, we are baffled, and unable to arrive at any satisfactory results; the arrangement seems to be almost altogether fortuitous. Probably it is not by accident that the three sonant mutes, *b, g, d*, come together, next after the *aleph*; nor that the three liquids, *l, m, n*, are also found side by side later; but all attempts at explanation beyond this are little better than mere guesses, and involve theories respecting the origin of the alphabet which reach far beyond our actual knowledge. For we really are wholly in the dark as to the antecedents of the old Semitic mode of writing; neither tradition and history, nor the traced relation of its characters to those of other modes of writing, nor their own shapes and names, afford ground for anything more than unrestrained conjecture. The names of the characters are each the name of some sensible and depictable object, which has for its initial the letter named: thus, *aleph*, ox; *beth*, house; *gimel*, camel; *daleth*, door; and so on. Considering that many Egyptian phonetic hieroglyphs are well known to have gained the office of representing certain sounds because those sounds were the initials of the objects depicted (thus, the eagle,

ahom, becoming a sign for *a*; the lion, *labo*, for *b*), the supposition has seemed a highly plausible one that the Phœnician letters also were originally rude pictures of the objects indicated by their names. And this supposition receives a degree of confirmation from a certain resemblance traceable in a few cases between the letter and the object: thus, the sign for *aleph* is not unlike the front of an ox's head; *mem*, water, is like one of the common conventional signs of water, a waving or indented surface; and *ain*, eye (our O), is a tolerable eye in outline. Yet the evidence of such a kind is too scanty to be much relied on, and it is quite as plausible a theory that names should have been chosen on acrophonic grounds for a set of signs otherwise originated; and that a few among them should happen to be, or should have been, chosen because they were suggestive of an object resembling the sign itself.—The Phœnician alphabet, as completed in system and worked over in shape by the Greeks and Romans, has become the most convenient and useful of all the modes of writing invented by men; and it has gone with European civilization over a great part of the globe. Efforts are making to introduce it among various eastern nations in substitution for their own more cumbrous and incomplete alphabets; but with little success hitherto, since national prepossession clings with especial tenacity to an institution so inwoven by tradition and custom with a nation's feeling as is its national mode of writing. Efforts, again, have been made to expand this alphabet, by diacritical marks and added signs, into a system capable of accurately representing all the various sounds (some scores in number) which are made by human organs in the utterance of language; the most conspicuous of these efforts is that of Prof. Lepsius of Berlin ("Standard Alphabet," &c., 2d edition, London and Berlin, 1863). Others, yet again, have devised alphabets founded on an analysis of the physical processes of production of each sound, and representing those processes by suggestive signs, so as to make each letter by its shape define the precise mode of its own utterance: for example, Dr. Brücke of Vienna ("Proceedings of the Vienna Academy," vol. xli., 1863), and Mr. A. M. Bell of London ("Visible Speech," &c., London, 1867). Into an account of these attempts we cannot here enter. Nor can we speak in detail of the other alphabets invented and in use among other parts of the human race. Respecting some of them, the articles on special languages, and that on *WERRING*, will give information.—In order to make clearer the relations of the Greek and Latin to the Phœnician or ancient Semitic alphabet, as they have been described above, the following comparative table is given. The first or left-hand column presents the Phœnician letters: their forms (which vary more or less considerably in records of different age and locality) are in part those of the great Sidonian monument of King Eshmunzer

(probably 500 B. C.), in part those of the recently discovered Moabite inscription of King Mesha (earlier than 800 B. C.); the prefixed names have their Hebrew version, and their correspondence with the Greek is apparent at a glance. The second column gives the forms of the letters as first employed by the Greeks, when writing from right to left. In the third are seen the Greek letters as finally adopted, being made to face in the other direction and somewhat further modified in form. The fourth column is that of the Latin letters; here some of the earlier forms are added to those with which we are familiar, for the purpose of illustrating the transition more fully.

	Phœnician.	Earliest Greek.	Letter Greek.	Latin.
1. aleph.....	א	Α	Α	Δ Α
2. beth.....	ב	Β	Β	Β Β
3. gimel.....	ג	Γ	Γ	Γ < C

21. shin.....	ש	Σ	Σ	Σ Σ
22. tav.....	ת	Τ	Τ	Τ Τ

ALPHEUS, the ancient name of the Ruplia, a river of Peloponnesus, which rises in southern Arcadia, and, flowing through Elis and the Olympian plain, discharges itself into the Ionian sea. The Alpheus, at a little distance from its source, twice disappears under ground, which gave rise to the myth of the god of the river, and the nymph Arethusa, whom Diana essayed to save from his embraces by transforming her into a fountain, and placing her in the Ortygian isle, near Sicily. The god made a passage for his

river beneath the intervening sea, and commingled its waters with those of the fountain in Ortygia.

ALPINE, an E. county of California, bounded N. E. by Nevada; area, 1,000 sq. m.; pop. in 1870, 685. The western portion is occupied by the Sierra Nevada range, including Carson's pass and Pyramid peak. It is rich in silver. In 1870 there were 57,165 sheep, producing 281,700 lbs. of wool. The other productions were small. There were 3 quartz mills, 8 saw mills, and 2 newspapers. Capital, Silver Mountain.

ALPS, the highest and most remarkable chain of mountains in Europe, forming the watershed between the rivers which discharge their waters into the Mediterranean, and those which run to the Atlantic ocean, the North sea, and the Black sea. The Alps have a general crescent-like form, and extend through fourteen degrees of longitude and five of latitude. From the principal chains spurs extend to the Apennines, the Pyrenees, the Vosges, the Hartz, the Sudetes, the Carpathians, and the Balkan. The average height of the different ranges is about 7,700 ft., from which altitude more than 400 peaks rise into the region of perpetual snow. The principal subdivisions of the Alps are the following: I. The Maritime Alps, consisting of two portions, of which the first, distinguished as Ligurian Alps, extends in a semicircle from the S. W. extremity of the Alpine chain to the Col de Lauzania in Piedmont, and forms the line of separation between that province and the French department of Alpes-Maritimes (the former circle of Nice); the second, distinguished as the Upper Maritime Alps, terminates on the W. frontier of Piedmont in the lofty peak of Monte Viso. The principal altitudes of the Maritime Alps are: peak to the W. of the village of Maurizio, 13,107 ft.; Monte Viso, 12,582 ft.; Monte Pelvo, 9,958 ft.; Col de Maurin, 9,784 ft. II. The Cottian Alps, extending, in a triangular form, from Monte Viso to Mont Cenis, having Piedmont on one side, Savoy on another, and the department of Hautes-Alpes in France on the third. They give rise to the Durance, the Po, and several smaller streams. The principal summits are: Mont Olan, 13,831 ft.; Mont Pelvoux, 13,440; Mont Galéon, 12,467; Mont Genève, 11,785. III. The Graian Alps, the Gray Alps of the German geographers, extending from Mont Cenis to the Col du Bonhomme, between Savoy on the W. and Piedmont on the E., giving rise to several tributaries of the Po and the Rhône. The most elevated summits in this chain are: Mont Iséran, 13,274 ft.; Aiguille de la Sassièrre, 12,346; Rocca Melone, 11,569; Mont Cenis, 11,457. IV. The Pennine Alps, extending from the Col du Bonhomme to Monte Rosa, between upper Savoy and the Swiss canton of Valais on one side, and Piedmont on the other. This chain includes the three loftiest mountains in Europe, as well as several other peaks of considerable elevation, namely: Mont Blanc, 15,732 ft.; Mont

Rosa, 15,150; Mont Cervin, 14,835; Le Géant, 13,800; Aiguille du Midi, 12,743; Mont Velan, 11,063; Pic Blanc, E. of Monte Rosa, 11,190. V. The Lepontine or Helvetic Alps, including the divergent chain known as the Bernese Alps. This division covers western Switzerland, extending on both sides of the Rhône, dividing Lombardy from Switzerland, and one branch terminating at Monte Bernardino, while the other extends to and unites with the Jura mountains N. of Lake Geneva. This portion of the Alps is more visited than any other, and comprises the finest mountain scenery in Europe. Its most elevated peaks are: the Finsteraarhorn, 14,106 ft.; the Furca, 14,037; the Jungfrau, 13,718; the Mönch, 13,498; the Schreckhorn, 13,386; the Eiger, 13,075; the Blänlis Alp, 12,140; Monte Leone, on the Simplon, 11,541; the Galenstock, the highest of the St. Gothard group, 12,481; the Moschelhorn, in the Rheinwald, 10,870; the Grimsel, 9,704. VI. The Rhetian Alps, commencing at Monte Bernardino, extending along the frontiers of Switzerland, Italy, and Germany, and terminating at the N. E. extremity of the Tyrol. The principal summits are: Mount Julier, 13,855 ft.; the Ortler-spitze, 12,852; Monte della Disgrazia, 12,060; the Wetterhorn, 12,176; Monte Gavis, 11,754; the Dödi, 11,735; and several other peaks of nearly the same altitude. VII. The Noric Alps, commencing at Dreiherrnspitze, where the preceding division terminates, extend through Salzburg, northern Carinthia, Styria, and Upper and Lower Austria, forming the dividing line of the basins of the Salza and the Drave. Their highest peaks are: the Gross-Glockner, on the confines of Tyrol and Salzburg, 12,776 ft.; the Wisbachhorn, in Carinthia, 11,518; the Hohenwart, in Carinthia, 11,075; together with several other summits nearly 10,000 feet high. VIII. The Carnic Alps, extending, on the confines of Venetia and Carinthia, from Pellegrino to Terlgou, separating the waters of the Gail from those that flow into the gulf of Venice, and sending out a spur to divide the waters of the Save and the Drave. Its highest peak is La Marmoluta, 11,508 ft. IX. From Terlgou this chain is prolonged through Görz and Carniola to Mount Kleek under the name of the Julian or Pannonian Alps. Its loftiest summit is the Terlgou, 10,866 ft. X. A southern continuation, called the Dinaric Alps, extends from Mount Kleek through Croatia, Dalmatia, and Herzegovina, to the neighborhood of the Balkan. The St. Gothard range is the culminating point of all these chains of the Alps, and is distant in a direct line from the Mediterranean about 150 miles, 225 from the Adriatic, 525 from the Atlantic, 500 from the North sea, and 550 from the Baltic. It will be evident from these distances that the southern slope is far more rapid and precipitous than the northern. —The line of permanent snow for the whole Alps averages about 8,000 to 9,000 feet of altitude. On the northern slope it is usually 600

or 700 feet lower than on the southern. The glaciers of the Alps (German, *Gletscher*) form one of the most remarkable features. From the peaks, more than 400 in number, which rise above the line of perpetual snow, there descends into the valleys below a mass of partially melted snow and comminuted ice, often of very great extent. Constantly pressed forward by the accumulation of ice and snow behind it, nothing can resist its onward progress; trees, rocks, houses, all are borne forward on its slow-moving surface, till it reaches the point where the sun's rays are sufficiently fervid to melt the mass, when it forms the source of some mighty river. Often these glaciers present a comparatively smooth surface, the pieces of ice of which they are composed varying in size from a pea to a walnut, but not un seldom they are rent by huge fissures, which are impassable by travellers. The most remarkable of these Alpine reservoirs are the glaciers of Mont Blanc, which cover an area of from 90 to 100 square miles. The Mer de Glace, the largest of these, on the northern declivity of the mountain, is 15 miles long, from 3 to 6 miles wide, and from 80 to 120 feet thick. (See GLACIER.) The whirlwinds of the Alps are worthy of notice, not only from their terrific violence, often overwhelming the hapless traveller with the blinding snow, but from their frequently setting in motion the dreaded avalanche. So precipitous are many of the slopes of the Alpine peaks, that the giving way of a slight barrier, a tree or boulder, perhaps, is sufficient to detach from its original position a vast mass of snow and ice; this, gathering force from its fall, brings sudden and inevitable destruction on whatever may be on its track, burying at times whole villages, crushing extensive forests, and filling up the beds of rivers. In some parts of the Alps, these masses are so delicately poised that the jar of a footstep, the ringing of a small bell, the breaking of a stick even, is sufficient to cause their precipitation. The optical illusions of the Alps, resulting from a condition of the atmosphere analogous to that of the mirage, have been the subject of much comment. The spectre of the Brocken is the most remarkable of these. It is observed on one of the summits of the Noric Alps. Mont Blanc, the highest mountain in Europe, was first ascended in 1786 by Jacques Balmat, and soon afterward by Dr. Paccard and De Saussure. Its ascent is now a common though dangerous feat of adventurous travellers.—The geological structure of the Alps has long puzzled geologists and given rise to most various and ably supported views. By some, the whole mass composing Mont Blanc and surrounding mountains was considered metamorphic and of comparatively recent date; others regarded the nucleus as primitive and of great antiquity, while the stratified rocks on the lower Alps were referred to different ages from carboniferous to miocene. The presence of carboniferous plants in forma-

tions containing nummulitic limestone was interpreted by some to indicate that the carboniferous flora survived longer in this region than elsewhere; while others explained the apparent anomaly by an inversion of strata. True granite is rare in the vicinity of Mont Blanc, but occurs in several localities, of which Valorsine is best known. Both here and at the Col de Balme and the Aiguilles Rouges a porphyroid granite sends veins into the adjacent gneiss, and appears to be true eruptive granite. Many of the apparently eruptive granites, however, are claimed by M. Alphonse Faure, who has recently (1867) published a valuable work on Alpine geology, as the results of aqueous infiltration. The protogine of the Alps seems to differ from ordinary granite in composition, according to Delesse, in the presence of one or two hundredths of oxide of iron and magnesia. The crystalline protogine forms the centre of Mont Blanc and other peaks, and appears in a curious fan-like form extruded through the secondary strata by breaks which Élie de Beaumont compares to gigantic buttonholes. The flanks are formed by crystalline schists. Both the protogine and the schists have been considered by all who have studied them stratified rocks, gneissic in structure, passing in places into more schistose varieties, and by no means well separated from each other or the chloritic, talcose, or mica schists of the flanks. The uncrystalline strata in the neighborhood of Mont Blanc includes representatives of the carboniferous, triassic, jurassic, neocomian, cretaceous, and tertiary. The anthracite system, as held by Scipion Gras, was estimated to have a thickness of 25,000 to 30,000 feet, and included, besides dolomites and gypsum, now referred by Faure to the triassic, layers of anthracite, coal plants, limestones containing belemnites of jurassic age, gneissic, micaceous, and talcose rocks supposed to be due to the local alteration of members of the anthracite system. To this miscellaneous collection Pillet added in 1860 nummulitic beds. The many recognized disturbances of the strata were made to explain all anomalies of grouping to the satisfaction of some, but Sismonda and Élie de Beaumont, in a memoir presented to the academy of sciences at Paris describing the sections exposed by the Mont Cenis tunnel, hold that there is no evidence of inversion, dislocation, or repetition in the series of 7,000 metres of strata. Faure indicates the geological history of Mont Blanc, and of the principal portions of the Alps, as follows: In a shallow ocean covering gneiss and crystalline schists, the carboniferous beds were deposited; some disturbance occurred, as secondary deposits are laid down unconformably over all the older formations, gneissic as well as carboniferous; then came the nummulitic limestones and their overlying sandstones, thus embracing a bed from the trias up of a thickness of about 3,800 feet; then came the great upheaval folding these strata, enclosing nummulites and coal plants in cry-stalline schists; then the work of

denudation removed the secondary strata, leaving a few evidences of their former existence, as in the beds more than 100 feet thick of jurassic and infra-jurassic age which cap the Aiguilles Rouges. The glacier action on the slopes of the Alps has been studied by De Saussure, Agassiz, Forbes, Tyndall, and others, and, from its extent and the comparative accessibility of the Alpine glaciers, has furnished ground for almost all the present knowledge of the geological work of snow and ice on mountain slopes. The formation of the Alps can no longer be considered an event of recent geological periods, at least so far as the cry-stalline rocks are concerned, although perhaps the extension and exposure of these ancient cry-stalline rocks may be recent geologically considered. The phenomenon of transportation of vast blocks of rock across Alpine valleys will be treated of in the article DRIFT. Many metals are abundantly distributed through the Alpine strata, which will be more particularly described under the head of the different countries in which they occur.—The great height of many of the Alpine summits gives an extraordinary variety to their vegetation. At the base of the mountains it is very rich and beautiful, commingling the productions of a temperate climate with those of a more elevated region, the result of the seeds brought down by the mountain torrents. At the height of 1,600 or 1,700 feet we find a change; the flora is less beautiful, though still rich and abundant; the *primula auricula* or bear's ear, the *gentiana acaulis*, the *aconitum napellus* or wolf's bane, the *trollius europæus*, and the *ranunculus aconitifolius*, are the most characteristic plants. At 3,300 feet the *soldanella alpina*, the *crocus vernus*, and two species of rhododendrons, adorn the declivities. At the height of 6,500 feet all the vegetation of the plains, including maize and the cereal grains, has disappeared; the common fruit and forest trees have ceased, and dwarfish larch, alder, and birch trees have taken their places, soon to be succeeded by the stunted pine, *pinus mughlo*, and *cembra*, above which, from the line of 7,450 to about 8,500 feet, extends pasturage of a very rich and nourishing character, and a flora which from its peculiar character is distinguished by botanists as alpine. Its principal genera are *androsace*, *silene*, *saxifraga*, *ranunculus*, *gentiana*, and *pyrethrum*. Of most of these, several species are found. Even amid the eternal snows, Agassiz distinguished several varieties of lichen.—Animal life is abundant throughout the Alpine chains. Herds of cattle find pasturage on their slopes; the wolf, fox, lynx, and wildcat abound in their forests; the bear hibernates in their caves; the marmot and the mole burrow in their pasture grounds. Several animals are peculiar to the regions; among these are the chamois, which inhabits the upper limit of the forest region, the mountain goat, and a species of white hare. Among the birds of prey, the lammergeier, a gigantic vulture, is

peculiar to the Alps, and, with the eagle, commits serious ravages on the sheepfolds of the loftier pasturage grounds. Nearly one half of all the known birds, resident or of passage, in central Europe, inhabit the Alps. The number of reptiles is not large, but four or five species of them are not found elsewhere. In the valleys of the Hautes-Alpes, the Basses-Alpes, Isère, Aosta, and the Grisons, as well as some other of the narrow and ill-ventilated ravines of the Alps, a large proportion of the inhabitants are affected with goitre and cretinism.—The Alps were formerly deemed almost impassable. Large bodies of men, hemmed in by the deep snows, perished miserably in attempting to cross them, and Hannibal's bold passage over them was considered for ages a more daring feat of military prowess than his subsequent victories. Now, however, nearly every portion is crossed by good roads. The principal roads crossing the Alps are over the following passes, of which the chief connect Switzerland with Italy: 1. The Mont Cenis, 6,773 feet high, built under Napoleon I. in 1803-'10, was crossed by diligences in eight hours, from St. Michel to Susa, connecting with the Chambéry and Turin railway. The temporary Fell railway, opened in 1868, has been superseded by the celebrated tunnel, which lies about 16 m. from the Mont Cenis pass. It was begun in 1857, and inaugurated at Bardonnèche, Sept. 17, 1871. On the Mont Cenis pass there is a hospice with 40 rooms. 2. The Little St. Bernard (hospice 7,076 feet high), one of the oldest and easiest passages, supposed to have been crossed by Hannibal, was designed by Napoleon I. as a military road connecting Grenoble with Aosta and thence with Turin. There is a carriage road from Courmayeur to La Thuile, and a new road was opened in 1863 from the hospice to Bourg St. Maurice. The latter place is reached from Courmayeur in about 9½ hours. The boundary line of France and Italy passes along the crest of the road. 3. The Col de Balme pass, 7,218 feet, from Martigny to Chamouni, is celebrated for its view of Mont Blanc, though inferior in variety to the Tête Noire pass (23 m.), which leads over the same ground and is much frequented. 4. The Great St. Bernard, 6,770 feet, from Martigny to Aosta, 47 m., connecting with Turin, and celebrated for its hospice and dogs. This pass was crossed by Napoleon I. with 30,000 men in 1800. 5. The Simplon, 6,628 feet high, a colossal work of Napoleon I., built in 1800-'6, extending from Brieg to Domo d'Ossola, 46½ m., connecting Geneva with Milan. The carriage road formerly began at Sierre, but the distance between that place and Brieg, 23½ m., is now passed by railway. 6. The new carriage road over the Furca pass, 8,150 feet, completed in 1867, and connecting the St. Gothard directly with the valley of the Rhône, has considerably increased the traffic across the Upper Valais, the Bernese Alps, and the Simplon. It runs closer to the glaciers

than any other road excepting the Stelvio. The Schreckhorn, the Finsteraarhorn, and the range from Monte Leone to the Weisshorn, are seen from this road. 7. The St. Gothard. A railroad over the St. Gothard pass (6,936 feet) is in course of construction, Italy contributing 45,000,000 francs, Switzerland 20,000,000, the North German Confederation 10,000,000, the grand duchy of Baden 3,000,000, and the other German states the additional cost. Until the completion of this railway, the road over the St. Gothard (built in 1820-'30) continues to be crossed by the diligence from Flüelen to Bellinzona in about 15 hours, connecting Lucerne with Milan. The passage was known to the Romans. Avalanches caused great loss of life in 1478, 1624, and 1814, the road being unprotected against precipices. Suvaroff's successes over the French in 1799 are recorded in an inscription on the top of the mountain. 8. Bernardino, 6,770 feet, built in 1822, extending from Coire to Bellinzona, distance by diligence 16 hours, and thence connecting with Milan. A bridge over the Rhine, below the village of Hinterrhein, the Marschhorn, and the Schwarzhorn, are the principal sights. The road was known to the Romans. 9. The Splügen, 6,495 feet, built in 1818-'22, crossed in about fourteen hours from Coire to Chiavenna, connecting with Milan. Macdonald's troops, while crossing the Splügen, Nov. 27 to Dec. 4, 1800, were almost buried by avalanches, nearly 100 men and as many horses being lost. 10. The Bernina, 7,672 feet, connecting the Engadine by way of Samaden and Tirano, 39 m., with the Valtellina. A footpath of 10 hours, up the Val de Fani to the Col de La Strella, leads to the baths of Bormio (Worms). The old path over the Bernina is so dangerous that horsemen prefer the huge circuit by Pisciadella. 11. The Julier pass, 7,558 feet, from Coire to the Engadine. The road begins at Churwalden and ends at Samaden. That by the Valbella pass meets the Julier road at Tiefenkasten, whence there are three passages, through the Julier, Valbella, and Albula passes, to the celebrated valley of the Inn. 12. The Stelvio pass, 9,100 feet, connecting Milan with Innspruck. It is the highest Alpine road practicable for carriages. It was built in 1820-'25 from Stelvio (Stilfs), a village of Tyrol, to Bormio, in the Valtellina, and extended in 1825-'34 to Lecco on the lake of Como. This pass is remarkable for glaciers, especially of the Ortles range, for the gorge of Spondalunga, and above all for the scenery of the lake of Como. The damage done to the road in the Austro-Italian war of 1859 has been repaired. 13. The principal road connecting Tyrol with Lombardy is the railway over the Brenner, from Innspruck to Botzen, opened in August, 1867. The old road, known to the Romans as Mons Brennius, has been accessible to carriages since 1772, and is crossed in four hours. This pass was one of the scenes of the Tyrolese rebellion of 1809. 14. The

Semmering railway, from Gloggnitz to Mürz-zuschlag, completing the connection between Trieste and Vienna, opened in July, 1854, and remarkable for its numerous tunnels and colossal viaducts, passes over the Semmering pass, which is situated on the boundary of Lower Austria and Styria. A hospice was built by a Styrian duke in the wilderness of the mountain in the 14th century. A carriage road completed in 1728 was superseded in 1840 by a new road. Besides these there are many passes of minor importance, though some of them remarkable for beautiful views and scenery. —The "Alpine Club," established in London in 1858, gave new impulse to explorations among these summits. The president of the club, Mr. J. Ball, has published "The Alpine Guide" (3 vols., 1863-7); and the "Alpine Journal," recording Alpine phenomena and ascents, has been published since 1863. Alpine clubs have since been established in Vienna (1862), Turin (1863), Bern (1863), Aosta (1868), and Munich (1869). The proceedings and explorations of these associations are recorded in various periodical publications, as the *Giornale delle Alpi, degli Appennini, e dei Vulcani*, published at Turin since 1864; the *Jahrbuch des österreichischen Alpenvereins*, at Vienna since 1865; *Jahrbuch des schweizer Alpenclubs*, at Bern since 1864; *Zeitschrift des deutschen Alpenvereins*, at Munich since 1869; *Alpenfreund*, at Gera since 1870; *L'Écho des Alpes*, at Geneva since 1870. The explorations in Switzerland are conducted systematically according to Dufour's topographical map, the Alpine club of Bern being divided into committees for expeditions to the different mountainous regions. The committee relating to the Glarus (Tödi) district caused a panorama of the Ruchen (Glarnisch) to be published by A. Hein (Glarus, 1870), with the statistics of about 350 mountains, peaks, passes, and lakes. —Among the principal recent works on the Alps are the brothers Schlagintweit's *Untersuchungen über die physikalische Geographie der Alpen* (Leipsic, 1850), and *Neue Untersuchungen über die physikalische Geographie und Geologie der Alpen* (1854); Prof. Tyndall's "Peaks, Passes, and Glaciers" (London, 1860-62), and "Mountaineering in 1861" (1862); Schaubach's "German Alps" (5th ed., 1864-7); Tschudi's *Thierleben der Alpenwelt* (8th ed., Jena, 1868); Edward Whymper's "Scrambles on the Alps, 1860-69, including the First Ascent of the Matterhorn and the Attempts which preceded it" (London, 1871); Berlepsch's *Alpen* (4th ed., 1871); and "The Switzers," by William Hepworth Dixon (London, 1872). Geological descriptions of the Alps are contained in Prof. Sedgwick's and Sir Roderick Murellison's contributions to the London geological society.

ALPUJARRAS, or **Alpuxarras** (Ar. *Al-Busharat*, Pasture Mountains), a mountainous region in the old province of Granada, Spain, lying between the Sierra Nevada and the Mediterranean, and including part of the modern

provinces of Granada and Almeria. After the taking of Granada by Ferdinand, the Moors remaining in the country were driven to this district, whence, after long struggles and desperate resistance, they were finally expelled by Philip III., in 1610. The Sierra de Gador, the highest summit, rises 6,550 feet above the sea level.

ALSACE (Ger. *Elsass*), formerly a province of France, bounded by Lorraine, the Palatinate, Baden, Switzerland, and Franche-Comté, and constituting the departments of Haut-Rhin and Bas-Rhin; since the treaty of May 10, 1871, the main part of the German Reichsland (imperial territory) of Alsace-Lorraine. It is now divided into the departments of Lower Alsace and Upper Alsace, and embraces an area of 3,175 sq. m., and a population of 1,083,886, exclusive of Belfort, formerly in Haut-Rhin, and some other portions of territory, which have been restored to France, and inclusive of some minor portions annexed from Lorraine. The Vosges mountains extend along its western side, and the northeastern offshoots of the Jura cross its southern limits; but the central and eastern part consists of a fertile plain lying along the western side of the Rhine, which here forms the boundary between it and Baden. The Ill and its tributaries are the other principal streams. There are several canals, of which the Rhône canal is the largest. The manufactures are important, comprising cloth of various kinds, cotton yarn, paper, beet-root sugar, beer, brandy, and oil. The principal cities are Strasburg, Mühlhausen, and Colmar. —As attested by monuments still extant, Alsace had a dense population of Celts several years before the Christian era. It was occupied by the Rauraci, the Tribocci, and the Nemetes at the time of the Roman invasion; was the theatre of the defeat of Ariovistus by Julius Cæsar, 58 B. C., and formed part of Celtic Gaul, as the Roman province of Germania Superior, called afterward Germania Prima. The Alemanni first invaded Alsace in the 3d century, and after the close of their long struggle with the Romans, the population, decimated by war, was rapidly filled up in the 5th century by Germanic settlers, who were called Ill-Sassen, *i. e.*, dwellers on the Ill, the main Alsatian affluent of the Rhine. After the defeat of the Alemanni near Zülpich in 496, Alsace became known under Frankish rulers as the duchy of Alsatia. In the 7th century, under the Frankish duke Adalric (Etticho) and his daughter Odilia, who became the patron saint of Alsace, great progress was made in Christianizing the country. In the 9th century it was part of Lothaire's empire. In 924 it was annexed to Germany by Henry the Fowler, but it was continually claimed as a Frankish possession until the extinction of the Carolingian dynasty in 987. It then remained for several centuries in the undisputed possession of Germany as an Alemannian or Swabian duchy, under various rulers and subjected to many vicissitudes. The

revolt of the Alsatian peasantry, the most violent outbreak during the religious conflicts of the 16th century, was quelled May 17, 1525, by the bloody victory achieved by Duke Anthony III. over the peasants. Part of Alsace was allotted to France by the treaty of Westphalia (1648). Strasburg was seized by Louis XIV. in 1681, and the whole country came under French authority by the treaty of Ryswick in 1697, with the exception of Montbéliard and Mülhausen, which were acquired by France

subsequently. In 1814 Saarlouis and Saarbrück were ceded to Prussia, and Landau and the adjoining localities to Bavaria. The French made strenuous efforts to Gallicize their Alsatian possessions, but German continued to be the language of the masses, except in the large cities, where the speech and modes of life of the upper classes were generally French. According to Böckh, in his work on the German-speaking nationalities in Europe (Berlin, 1870), there are hardly 100,000

out of the whole population who do not speak German. In the Franco-German war the recovery of the old German possessions of Alsace and Lorraine became a strong national aspiration. On July 22, 1870, the Rhine bridge at Kehl, opposite Strasburg, was blown up by the Germans. Weissenburg was stormed by them Aug. 4, and the battle of Wörth was fought Aug. 6. Strasburg surrendered Sept. 27, 1870; Schlettstadt, Oct. 24; Neu Breisach, Nov. 10; and Belfort, Feb. 16, 1871. Alsace was for-

mally ceded to the German empire by the treaty of peace of Frankfort, concluded May 10, 1871. W. Menzel, A. Schmidt, and Wagner wrote in 1870 on Alsace and Lorraine. Among recent French historians of Alsace are Boyer (Paris, 1862) and Baquol (3d ed., Paris, 1866).

ALSACE-LORRAINE (Ger. *Elsass-Lothringen*), a division of the German empire, officially designated as the German Reichsland (imperial territory), and composed of Alsace and those portions of Lorraine conquered from France in

the war of 1870, and formally ceded to Germany by the treaty of Frankfurt, May 10, 1871. It passed by the terms of its cession into the possession of the whole empire, and not of any one division of Germany, and it is under the immediate control of the imperial government. The territory originally occupied by the Germans in 1870, and formed in August of that year into a district under the temporary government of a governor general, included the French province of Alsace with its two departments Haut-Rhin and Bas-Rhin, two arrondissements (Kaufmanns-Saarbrück and Salzburg) of the department of Meurthe, and three arrondissements (Saargemünd, Metz, and Diedenhofen, Fr. *Thionville*) of the department of the Moselle. The canton of Schirmeck and a part of the canton of Saales, both from the department of Vosges, were added in December. The treaty of peace made important changes in the extent of these districts. The Germans restored to France the following portions of the conquered territory: 1. From the department of Haut-Rhin. Arrondissement of Belfort: the cantons Belfort, Delle, Giromagny, and 21 out of the 29 communes composing the canton of Fontaine. Arrondissement of Altkirch: three communes of the canton of Altkirch. Arrondissement of Colmar: four communes of the canton Masmünster. 2. From the department of Meurthe. Arrondissement of Saarburg: eight communes of the canton of Saarburg, and nine of the canton of Vic. Arrondissement of Salzburg: three communes of the canton of Salzburg. 3. From the department of Moselle. Arrondissement of Metz: 11 communes of the canton of Gorze. By an additional article, ratified in Berlin, Oct. 20, the comparatively unimportant communes of Raon-les-Leaux, Raon-sur-Plaine, and Igney, with a part of Avricourt, were also restored to France. By the treaty, however, there were ceded to Germany 12 communes of the cantons of Audun and Longwy, arrondissement of Briey, department of Moselle. The entire Reichsland, as permanently organized by Germany after these complicated changes, is bounded by Luxemburg, Rhenish Prussia, Rhenish Bavaria, Baden (from which it is separated by the Rhine), Switzerland, and the French departments of Haute-Saône, Vosges, and what remains of those of Meurthe and Moselle; area, 5,594 sq. m.; pop. in 1871, 1,549,459. The natural features of the country, and its history to 1870, are described in the articles ALSACE and LORRAINE.—The government, as organized by the Germans, centres in the provincial diet (*Landtag*). The Reichsland is divided into 23 circles (*Kreise*), each having a Kreisdirector at the head of its local government—an officer nearly corresponding to the sub-prefect of a French arrondissement. The old French division into communes (Ger. *Gemeinden*) and cantons (Ger. *Cantone*) is retained with some unimportant changes. Before its cession to Germany, the territory belonged to five French

departments, namely, Haut-Rhin, Bas-Rhin, Vosges, Meurthe, and Moselle; it is now divided into three *Bezirke* (districts), called Ober-Elsass (generally corresponding to the former Haut-Rhin), Nieder-Elsass (Bas-Rhin), and Deutsch-Lothringen (German Lorraine).—The educational establishments have been reestablished on the plan of similar German institutions, and education has been made by law independent of all sectarian influence. The language of the common people is generally German in Alsace; in Lorraine more French is spoken. Both languages are commonly understood, and near the former frontier both are used.

ALSEN, a Baltic island in the Little Belt, in lat. 55° N., lon. 10° E. It was taken from the Danes by the Prussians, June 29, 1864, and now constitutes, together with a portion of the opposite mainland (joined by a draw-bridge), the district of Sonderburg, in the Prussian province of Schleswig-Holstein; area, about 125 sq. m.; pop. in 1868, 34,551. The island is fertile, and contains fine woods and fresh-water lakes, which abound with fish.

ALSTED, Johann Heinrich, a German Protestant divine and author, born in 1588, died in 1638. He was for some time professor of philosophy and divinity at Herborn in Nassau, and afterward at Carlsburg in Transylvania. Among his writings are an *Encyclopadia*, in two large folios (Herborn, 1630), the most complete work of the kind that had then appeared; *Theaurus Chronologiae*; and *Triumphus Bibliorum Sacrorum*, intended to prove that the principles of all arts and sciences are contained in the Scriptures. His *Tractatus de Mille Annis* (1627) maintains that the millennium was to commence in 1694.

ALSTON, John, a merchant of Glasgow, and director of the asylum for the blind in that city, died in 1846. In 1832 the society for the encouragement of the useful arts in Scotland offered a gold medal for the best form of letter adapted to relief printing for the blind. Mr. Alston and Mr. Taylor of Norwich were constituted referees. An alphabet in Roman capitals was, after some modification by Mr. Alston, adopted by the society. From this time Mr. Alston devoted himself to the work of supplying the blind with books. The cost of preparing these is very great, yet Mr. Alston, aided by contributions, succeeded in publishing the Scriptures in 19 volumes, and 23 volumes of miscellaneous works, besides maps and cards.

ALSTRÖMER. I. Jonas, a public-spirited Swede, born of poor parents at Alingsås in West Gothland, Jan. 7, 1685, died June 2, 1761. He made a fortune in England by commercial speculations, and introduced into Sweden improved breeds of sheep, the culture of potatoes and of dye plants, established woollen and other manufactories at Alingsås, and contributed to the formation of the Levant and East India companies. He was ennobled and had a statue erected to him on the Stockholm exchange.

II. Klas, a botanist, son of the preceding, born

at Alingsås, Aug. 9, 1736, died March 5, 1796. A devoted pupil of Linnæus, he collected for him in his rambles over Europe, particularly Spain, various specimens of flowers, the most remarkable of which was that of a Peruvian plant, afterward extensively cultivated under the name of Alströmer lilies or incas.

ALTAI, a mountain range on the boundary between Russia and China, divided into various groups. The mountains were long designated as the Great and the Little Altai, and the name Altai is still occasionally applied to the vast network of ranges, chiefly in Chinese and partly in Russian territory, and extending, with irregular branches, from Siberia and China to the N. Pacific, diverging in many directions, intersected by numerous lakes and rivers, and including the Aldan and other mountains. The Altai range in a narrower sense extends from the vicinity of Tomsk, lat. 56° N., to the junction of the Bukhtarma and the Irtysh near Bukhtarminsk, lat. 50° N., and from the Kolyvan mountain on the west, lon. 82° E., to the Sayan chain on the east. The region embraced within these limits includes an area of about 40,000 sq. m., comprised in the Russian governments of Tomsk and Yeniseisk, principally in the former. The Altai system proper, sometimes called the Ore Altai on account of its mineral wealth, consists of several ridges extending from the banks of the Irtysh in a direction generally E. N. E. At their western extremity they rise above the valley of the Irtysh in hills about 500 or 600 ft. high, and within a distance of 15 or 20 m. attain a height of 3,000 or 5,000 ft.; this may be considered the average elevation of the greater part of the ranges, until they approach Lake Teletzkoi. Here they rise above the limit of perpetual snow, many of the peaks reaching an elevation of 10,000 ft., and are known as the Altai Bieli. Beyond Lake Teletzkoi there are two well defined ranges, the principal of which, called the Tangu Oola, is within the Chinese boundary, and is imperfectly known. The other is pierced by the river Yenisei, which divides it into the Sayanian range and the Ergik Targak Taiga. Eastward of this point the mountains stretch away into the independent chains running E. and N. E. as far as the sea of Okhotsk, and formerly included in the general appellation of the Altai system. Geologically the mountains have been described as a rocky promontory jutting out from the mainland of primitive rocks which forms the table land of Chinese Tartary on the S. into the ocean of diluvial deposits which forms the great Siberian plain. The geological formations, however, have not been carefully studied. Stratified rocks not yet classified form the greater portion of the Altai range. Clay slate, chlorite slate, and mica slate abound in the upper districts; and through these granite, gneiss, syenite, porphyry, and greenstone have forced their way. Limestone, carboniferous limestone, and sandstones especially rich in fossil remains, are also

found. The metals are gold, silver, copper, and lead, mines of which at some unknown remote period were worked to a great extent by some unknown people. They were reopened by the Russians in the last century at the W. end of the range; but of late attention has been given almost wholly to the washing of detritus brought down by the Irtysh, Obi, Yenisei, and other rivers, whose sands are rich in gold. The product of the other ores is not important. The diminished production of silver being ascribed to the exhaustion of the mines, investigations were instituted by Professor B. von Cotta at the instance of the czar (1858), and resulted in the publication of his geological and mineralogical work on the Altai (Leipsic, 1871). The scenery is grand, especially among the stupendous rocks and glaciers in the heart of the mountains, on the banks of the Katunya. The two pillars of the Katunya are the highest peaks of the Altai, rising to nearly 13,000 ft. The short summer is excessively hot. The extreme cold of the winter is made salutary by the clearness of the atmosphere. In the forests are birch, alder, aspen, acacia, willow, larch, fir, and Siberian stone pine trees. The dried leaves of the *saxifraga crassifolia*, used as a substitute for tea, are gathered in the Tchernaya mountain. The animals of the Altai region are bears, wolves, foxes, lynxes, mountain hares, wild sheep and boars, wild goats, muskions, and occasionally tigers. Venomous serpents are found in the valleys. The best furs are obtained from black-skinned sables, as well as from martens and from the kulonok (*mustela Sibirica*). A marmot peculiar to the Altai haunts the snow. There are otters, beavers, musk deer, numerous elks, large stags, and red deer. The most remarkable bird is the mountain swallow (*hirundo alpestris* or *Daurica*). Among the fishes are red and other salmon, eel pouts, pike, sterlet, and sturgeons; great numbers of the last are used for the manufacture of isinglass and caviare. There are excellent horses, fat-tailed sheep, and a few camels. Game, poultry, and bees abound. Mosquitoes are numerous in summer, especially in the lowlands. Most of the cereals are successfully cultivated, and even melons in the W. part.—The inhabitants of the Altai consist chiefly of white Kalnucks or Teleuts in the east, near Lake Teletzkoi, and the nomadic mountaineer Kalnucks in the southeast. They are governed by native chiefs, the Russian government interfering little with them excepting for the collection of the tribute of furs, to which even some of the tribes living beyond Russian jurisdiction are made amenable. Excepting the peasantry on the north and northwest, chiefly descendants of fugitive Russian serfs, who belong to the orthodox church, and a few tribes of Mohammedan descent, the great bulk of the Altai population are pagans worshipping in temples. Carsten's "Ethnological Lectures on the Altai" (St. Petersburg, 1851) divides the Altai nationalities and languages

into Tungusian, Mongolian, Tartar, Finnish, and Samoyed groups, subdivided into various branches, with different vernaculars. Peddlers from the provinces of Moscow and Vladimir periodically visit the Altai, and the great route of travel between St. Petersburg and Peking crosses the range near Lake Baikal, Kioklita being the Russian frontier town and Maimuteilin the Chinese. The Chinese Altai territory, which is little known, is chiefly situated east of the upper Bukhtarne and Lake Dzaiyang. The settled Russian Altai region is mainly comprised in the district of Kolyvan Voskresenski, the Russian designation of the mining region of the province of Tomsk, western Siberia, and which includes, besides the S. part of a district of the same name, the districts of Kolyvan, Barnaul, Kuznetzk, and Biisk; area, over 13,000 sq. m.; pop. 350,000.

ALTAMAHA, a river of Georgia, about 140 m. long, which is formed by the confluence of the Oronce and the Oemulgee, in the S. E. central part of the state. Its course is S. E. through sandy plains and pine barrens to the Atlantic, about 12 m. below Darien, and about 60 m. S. W. of Savannah. For vessels of 30 tons it is navigable through its entire extent.

ALTAMIRA, a town of S. Italy, capital of a district of the same name, in the province of Terra di Bari, 28 m. S. W. of Bari; pop. about 18,000. It is walled and beautifully situated in a fertile pastoral country. Neighboring remains are supposed to mark the site of Lupatua, a town of Apulia on the Appian way. The modern town was settled in the 13th century by colonists from Greece, and many of the present inhabitants are of Albanian origin and still wear the Albanian costume. The emperor Frederick II. endowed the town with a magnificent cathedral, and it also contains a college, a hospital, an episcopal palace, and other fine buildings. There are two annual fairs, and the principal products of the vicinity are wine and olives.

ALTAR (Lat. *altus*, high), a place or structure, usually elevated, on which to perform certain religious services. The use of altars in religious worship reaches back beyond the historical era. The earliest account we have of an altar (Gen. viii. 20) shows that it was used for the offering of sacrifices. Later in Biblical history, we find altars sometimes built apparently as memorials of some religious event, and sometimes with a further idea of a distinct act of worship, as where Jacob built an altar and poured a drink offering thereon. Generally, however, the idea of sacrifice attended the altar. In the Jewish system there were two altars, viz., of incense and of burnt offering, besides the table for the shew-bread. Among the surrounding heathen nations, the same custom of erecting altars for purposes of worship may be traced to the earliest antiquity. The altars of Baal, that god of the oldest pagan cultus, are frequently mentioned in Scripture. Among the Greeks and Romans

altars were erected to the various gods, and the services varied according to the character and functions of the divinities to which they were dedicated. The materials used in the construction of the ancient altars at first were probably rude stones. In Egypt they were highly wrought with sculptured representations of the gods. The Israelites at their exodus were therefore commanded to make their altars of earth, so that they could not violate the second commandment. Afterward they were made of shittim (acacia) wood and cedar, overlaid with precious metals. The Greeks and Romans made them of earth and rude stones at first, then of highly sculptured stone. There are to this day many cairns of stones in the northern part of Britain, which were probably ancient altars. Similar structures are found on the high tops of the Anti-Libanus range, and some of the structures found in Mexico and the valley of the Mississippi, and in South America, may have been erected for the same purpose. The form of altars has varied among various nations and at different times, as also their elevation. The Jews were forbidden to go up to their altars by steps. In the Latin and oriental churches, the altar is an elevated structure, on which the priest offers the sacrifice of the mass. In the Roman Catholic church, a permanent altar is a solid structure, the top of which must be a slab of stone. Within the altar is a hollow receptacle for the relics of martyrs or other saints, called the sepulchre. The altar is consecrated by a bishop with chrism. A portable altar is a small slab of stone, usually marble, consecrated and containing relics, which is placed on temporary or ordinary wooden and unconsecrated altars, in such a position that the oblation can be placed on it. Where there is sufficient wealth to permit it, the most costly marbles are used in the construction of altars, and the most sumptuous decorations are employed in their adornment. Altars on which the sacrament is reserved have a tabernacle, made in the shape of a small temple. In the East the altars have, instead of a tabernacle, an urn or casket suspended from the ceiling, in which the consecrated hosts are kept. In some Lutheran churches the altar has been retained. Some of the ancient altars remain also in the English churches, though they have been covered in some way, or at least disused. Generally speaking, altars have been abolished in the Protestant churches, and the existence of any such thing as an altar in pure Christian worship is denied. In the church of England and the Protestant Episcopal church of the United States there are, and always have been, many who advocate the use of an altar in place of a common table, and solid altars are to be seen in some churches; occasionally even very beautiful altars of marble, with emblematic devices, rich altar cloths, altar pieces, and conspicuous crosses. The liturgy, however, substitutes the word "table" in place of "altar,"

which occurs only in one or two occasional offices. In the early church the tombs of the martyrs, especially in the catacombs, were frequently used as altars, whence the present form is evidently derived. The earliest Christian writers use the words *mensa sacra*, *mensa Domini*, *Θυσιαστήριον*, and *altare*, indiscriminately as convertible terms. In the small early churches the altar stood on the floor of the sanctuary; in the churches of the 4th century, which were larger, it was elevated on a platform; and it was subsequently elevated still more, so as to be reached by an ascent of several steps. Until the 13th century it stood in the middle of the sanctuary, and the priest stood behind it, facing the people, as is still the case in the Lateran basilica. Afterward the altar was placed against the wall, or a screen, which occasioned the change in the posture of the priest. This seems to have been peculiar to Rome, however, as elsewhere there is no record of a change in this respect.

ALTDORF, or **Altorf**, a town of Bavaria, in the circle of Middle Franconia, 13 m. S. E. of Nuremberg, on the Schwarzach; pop. about 3,000. It contains an old palace, and manufactories of wooden toys and breweries. The principal trade is in hops. It was an imperial city before the 13th century, and again rose to importance in the 17th, through its university, which in 1806 was merged in that of Erlangen. The university buildings have since been occupied by a normal school for Protestant teachers.

ALTDORFER, **Albrecht**, a German painter and engraver, born at Altdorf, Bavaria, in 1488, died at Ratisbon in 1538. He is supposed to have been a pupil of Albert Dürer, and is distinguished in Germany for the romantic character of his conceptions. His principal painting, "The Victory of Alexander over Darius," is in the gallery of Schleissheim, near Munich, and his "Birth of our Saviour" in the imperial gallery of Vienna. His engravings are on both copper and wood.

ALTENA, a town of Westphalia, Prussia, on the Ruhr and Sieg railroad, in the district and 17 m. W. S. W. of Arnsberg; pop. in 1871, 7,122. It is situated in a beautiful valley surrounded on all sides by high mountains. The town has for centuries been the seat of a flourishing industry, comprising numerous manufactories of iron and steel wares. Near by, on a high cliff, is the castle of the old counts of Altena (later counts of the Mark), which now belongs to the order of St. John.

ALTENBURG. **I.** Or **Saxe-Altenburg**, a sovereign duchy of the German empire, bounded by Prussia, Saxony, Weimar, Meiningen, Rudolstadt, and Reuss-Gera, the last of which divides it into two parts, the E. division constituting Altenburg proper and the W. Saal-Eisenberg; area, 510 sq. m.; pop. in 1871, 142,122. It is traversed by spurs of the Erzgebirge, and in the west by ridges of the Thuringian Forest. The principal rivers are the Pleisse and the Saale. The duchy contains several large lakes and

mineral springs, extensive forests in the west, and coal mines in the east. It is among the richest in Germany in agricultural products, especially in rye and wheat; a great many cattle are raised, and the horse and sheep are of superior breed. Wild boars and deer abound. The manufactures are leather, woollen cloths, hosiery, linen goods, wooden wares, and brandy. The duchy joined the North German confederation in 1866, where it had one vote, which it also has in the empire. The local legislature or diet consists of one chamber with 30 members. The present duke, Ernest, who succeeded his father in 1853, is a general in the Prussian and a major general in the Saxon army. In former times the duchy belonged to the Osterland, and was ruled by the margraves of Pleissen. In 1803 it was divided into two principalities. In 1826 it assumed its present territorial form. The inhabitants are chiefly Wends by descent, and many in the rural districts retain the antique costumes. **II.** A city, capital of the preceding duchy, situated on the Pleisse, 24 m. by railway S. of Leipsic; pop. in 1871, 19,966. It is well built, and contains many churches, a museum of painting and statuary, a gymnasium, and a great number of educational and literary institutions. The most celebrated public building is the palace, situated on an escarped rock. Altenburg has manufactories of cigars, gloves, brushes, and haberdashery, and an important book trade. It was for some time an imperial city. In 1430 it was almost destroyed by the Hussites.

ALTEN-OETTING, or **Alt-Oetting** (the *Aulinga Tilla* of the middle ages), a small town in one of the most beautiful and fertile valleys of Upper Bavaria, 50 m. E. N. E. of Munich, and 2 m. S. of Neu-Oetting on the Inn; pop. about 2,500. It is annually frequented, on account of its famed picture of the Virgin, by many thousand pilgrims from Austria, Bavaria, and Swabia. The Jesuits had a college here, which was suppressed in 1773. In its place the Redemptorists founded a college in 1841, which is the principal house of the order in Germany. Alten-Oetting was in the 9th century long the residence of Carloman, the eldest son of Louis the German. Several German emperors, among whom are Henry III. and Henry IV., held their court here. Tilly is here buried with other members of his family, and the chapel which contains his tomb bears his name. Since Maximilian I. many princes and princesses of the Bavarian house have been entombed here.

ALTENSTEIN, a mountain castle in Saxe-Meiningen, not far from Eisenach, on the S. W. slope of the Thuringian Forest. It was the residence of Boniface, the apostle to the Germans, in the 8th century, and just behind it is the place where Luther was secreted by the elector Frederick the Wise in 1521. The names of "Luther's beech" and "Luther's spring" perpetuate the memory of the reformer's retirement in this place. The tree stood till 1841, when it was shattered by a tempest, and

a part of its fragments are preserved in the church of Steinbach; a small monument marks the place where it stood. Since 1798 Altenstein has been the summer residence of the court, and has been surrounded by a splendid park. In 1799 a grotto was here discovered, which is among the most remarkable natural curiosities of Germany. It is of vast proportions, and through its whole extent flows a rapid stream of water sufficiently deep to bear barges, and turning a mill at the place where it issues from the earth. The entrance to the cavern is through a subterranean gallery.

ALTENSTEIN, Karl, baron von Stein zam Altenstein, a Prussian minister of state, born in Anspach, Oct. 7, 1770, died in Berlin, May 14, 1840. He was called by Hardenberg into the ministry at Berlin in 1799. During the war of 1806 he fled with the court from Berlin to Königsberg, and after the treaty of Tilsit became the head of the department of finance. He took a principal part in the foundation of the university of Berlin in 1809. In 1815 he was sent with Wilhelm von Humboldt to Paris, to present the claims of Prussia for the restoration of the treasures of art and literature carried from the country by the French armies; and in the same year he was made a member of the commission for determining the boundaries of the Prussian possessions in Westphalia and in the province of the Rhine. After his return to Berlin he was made minister of public worship and education, and in this position he rendered lasting service to the universities, gymnasiums, and schools. Under his direction the university of Bonn was founded, and reforms were introduced into the several branches of popular instruction. He was a zealous partisan of the philosopher Fichte.

ALTERATIVES, a term applied by modern writers on medical science in a somewhat obscure manner. A certain class of substances are denominated "alteratives" in manuals of therapeutics. The effects produced by these substances, administered in comparatively small and frequent doses, are practically known, but the *modus operandi* is a mystery. As the same substances in large doses act as emetics, purgatives, or poisons, a name was required to designate the peculiar effects of these substances administered in minute doses; and the most appropriate word that could be found, apparently, was the word "alterative." As the manner of action of drugs in health and disease becomes more accurately known, the medicines thus designated will undoubtedly be removed to other classes, or this name will be replaced by something more rational and definite. It is probable that some alteratives act either by modifying the character of the nutritive material carried by the blood to the tissues, or by promoting the destructive metamorphosis of tissue outside the blood vessels. In these processes, diseased tissues, being the more weakly organized, experience the earliest effects, and in this way the good may be ob-

tained without the evil. The principal substances used as alteratives are iodine and mercury, and their respective combinations with potassium and other substances. Arsenical preparations are also used as alteratives in small doses. They are mostly employed in chronic diseases and cutaneous, scrofulous, and syphilitic affections. Many other substances are now used as alteratives in small doses, the effects being more or less immediate and temporary, or slow and lasting, according to the dose administered. Any powerful medicine given in frequent small doses may be called an alterative, therefore, as it acts continuously, gently, slowly, and, when well selected, often most efficiently. Each medicinal substance acts in proportion to the frequency and potency of the dose administered, when given alone, or with a neutral menstruum, such as mucilage or water. Ten grains of ipecacuanha, taken alone or in water, act as an emetic; but combined with a strong dose of opium (two grains of good quality, or three of an inferior kind), the ipecacuanha will not produce an obvious effect upon the stomach, but be absorbed into the blood and cause a profuse flow of perspiration, if the patient be kept warm in bed. Arsenic is a violent poison in large doses; in minute doses, frequently repeated, it is a cure for ague and fever. Many of the most active and poisonous preparations of mercury are highly beneficial in small doses, although dangerous in large ones.

ALTERNATE GENERATION. See JELLY FISH.

ALTHEA (Gr. *althēa*, to cure), a genus of plants belonging to the natural order *malvaceæ*. They have a double calyx, the outer whorl with from 6 to 9 sepals, and the inner with 5. *A. officinalis* is the marsh mallow, the knowledge of which in medical botany is of great antiquity. The mucilaginous roots and leaves of this plant are used in all cases in which emollient or demulcent substances are required. It is a perennial plant, with a white, fleshy root, 12 or 15 inches long. The stems are 2 or 3 feet high, and covered all over with a soft down. The leaves are also covered with down, which gives the whole plant a hoary aspect. The leaves are soft and stalked, the flowers of a pale rose color, appearing in very short clusters from the axil of the leaves. The corolla is like that of the common mallow. The demulcent lozenges sold under the name of *pâte de guimauve* are made of *A. officinalis*; they are made in large quantities in the south of France, particularly at Marseilles. The hollyhock, *A. rosea*, grows wild in China. (See HOLLYHOCK.)—*Althæa* is a common name of the ornamental shrub *hibiscus Syriacus*, also called rose of Sharon. (See Hibiscus.)

ALTHEN, Ehan, a Persian who introduced madder into France, born in 1711, died in 1774. He was sold to an Anatolian planter, who for 14 years kept him working on cotton and madder. On effecting his escape from slavery, he found his way from Smyrna to Marseilles and

Avignon, where the soil seemed to him favorable to the growth of madder. He failed to interest the public mind in favor of his plan, but a French lady, Mme. de Clausenette, consented to plant the seeds which he had brought with him from Smyrna. The experiment was successful and extensively imitated, but Althen, who had thus conferred a great benefit upon France, was left to die in the greatest penury; and on the same day that the honor of a monument in the Calvet museum at Avignon was paid to him by the French authorities, his only daughter died in despair at the hospital.

ALTHORP, Viscount. See **SPEYCE**.

ALTITUDE, the scientific or technical word for height. The altitude of a triangle is the distance from either corner of the triangle to the opposite side, when that side is considered as the base of the triangle. The altitude of a cone or a pyramid is the height of its vertex above the plane on which it stands. The altitude of a star is its height above the horizon. This altitude is measured in degrees, a star in the zenith having the greatest possible altitude of 90 degrees. Apparent altitude is that which the star or other heavenly body appears to have, from which the true altitude is obtained by making allowance for the various errors arising from the refraction of the air, the height of the observer, the distance of the body from the earth, &c.

ALTKIRCH, a town of the new German department of Upper Alsace, on the Ill, 16 m. E. of Belfort, France, and 70 m. S. of Strasburg; pop. about 3,200. It is a manufacturing town of some importance, and contains a fine modern church and a ruined castle, which in former times was occupied by the Austrian archdukes in their visits to Alsace. It was founded in the 12th century, and belonged to the counts of Pfirt (Ferrette). The German authorities have selected Altkirch as the town to be fortified as a counter-fortress to Belfort.

ALTMÜLL, a river of Bavaria, 150 m. long, rising 7 m. N. E. of Rothenburg in Middle Franconia, and emptying into the Danube at Kellheim, S. W. of Ratisbon. The Ludwig's canal connects it with the Regnitz, an affluent of the Main, thus uniting the North and Black seas through the Rhine and Danube.

ALT-OETTING. See **ALLEN-OETTING**.

ALTON, a city and port of entry of Madison county, Ill., on the left bank of the Mississippi river, 3 m. above the mouth of the Missouri, about 20 m. below the mouth of the Illinois, and 25 m. N. of St. Louis, Mo.; pop. in 1860, 6,332; in 1870, 8,895. Its length along the river is about 2½ m.; its average breadth about 1½ m. A little W. of the centre it is divided by a small stream called Piasa creek, which has its sources in springs within and near the city limits, and is arched over and used as a main sewer. The valley of this stream and the bottom land W. of its mouth along the Mississippi are the chief seats of business. Each side of this valley and up and down the river from it

the ground rises rapidly and in some parts abruptly into irregular and broken bluffs, the highest being 224½ feet above the river. The whole city is underlaid with limestone rock, which is full of fissures and caves, crops out in many places, and in the western part along the river forms perpendicular bluffs. Alton is the centre of a rich farming country. Besides the river navigation, three railroads connect it with all parts of the country. The principal manufacturing establishments (1872) are two large flouring mills, two iron foundries, an extensive woollen mill, glass works, a castor oil mill, a large tobacco manufactory, a manufactory of agricultural implements, a planing mill, and several lumber yards and steam saw mills. The packing business is carried on, but less extensively than formerly. Lard of excellent quality is made, and, with building stone, is exported largely. There are two banking houses, gas works, and a steam ferry to the opposite shore. There is a large Roman Catholic cathedral, Alton having been made a bishopric in 1868. The other churches are: one Baptist, one orthodox Congregational, one Unitarian, two Protestant German, one Presbyterian, one Cumberland Presbyterian, one Methodist, one Catholic, and one colored Baptist. Alton has a daily and weekly newspaper, a weekly paper in German, and a weekly religious journal, the "Cumberland Presbyterian," the organ of that denomination in the West. There are several benevolent societies and a library association. The state penitentiary, established here in 1827, was removed several years since to Joliet. The buildings are yet standing, and were used during the civil war as a government prison. Upper Alton, about 1½ m. E., is the seat of Shurtleff college, a Baptist institution. (See **SHURTLEFF COLLEGE**.) In 1807 there was one small building where Alton now stands, used by the French of Calokkia and St. Louis as a trading house with the Indians. The town was laid out in 1817.

ALTON, an Austrian noble family, of Irish descent. **I. Richard**, count d', a general, born in Ireland in 1732, died in Treves, Feb. 19, 1790. He entered the Austrian service very young, rapidly rose to high rank, and in 1788 became Feldzeugmeister. In November, 1787, he was appointed to the command of the Austrian Netherlands, then in insurrectionary ferment. His harsh measures provoked the first bloodshed at Brussels, June 22, 1788. After the victory of the patriots at Turnhout, Oct. 27, 1789, he gave the order to destroy all rebellious places; but in December, after the outbreak in Brussels, he retreated to Luxemburg, and was recalled to Vienna, but died on the way thither. **II. Edward**, count d', brother of the preceding, also a general, born in Ireland in 1737, died Aug. 24, 1793. He distinguished himself in the seven years' and Turkish wars. In 1792 he was imprisoned for writing in defence of his brother's conduct, but afterward commanded a division at the siege

of Valenciennes and a corps at that of Dunkirk, where he was killed. **III. Johann Wilhelm Eduard** d., a German naturalist, born in Aquileia in 1772, died in Bonn, May 11, 1840. He was educated at Vienna, visited Italy, and lived for a long time in the grand ducal park at Tiefurt, near Weimar, where he devoted himself to the study of the fine arts and natural history, especially of the horse. In 1817 and 1818, in company with his friend Pander, he explored France, Spain, Portugal, and Great Britain, for scientific purposes. On his return he became professor of archaeology and fine arts at the university of Bonn. He left a fine collection of paintings and engravings, part of which were purchased by the university and part by Prince Albert, who was one of his Bonn pupils. D'Alton is the author of works on the "Natural History of the Horse" and "Comparative Osteology," accompanied with many superb plates, engraved by himself. He took an active part in Döllinger's and Pander's investigations on the development of chickens in the egg. **IV. Johann Samuel Eduard**, son of the preceding, born at St. Goar, July 17, 1803, died in Halle, July 25, 1854. In 1834 he was appointed professor of anatomy and physiology at Halle. He continued the "Comparative Osteology" of his father, and published between 1827 and 1838 two volumes on the ostrich and birds of prey. In 1850 he published the first volume of his manual of the "Comparative Anatomy of Man." In 1853 he published *De Monstris, quibus Extremitates Superflue suspensae sunt*, and in 1854, in concert with Burmeister, *Der fossile Gaviol von Boll in Württemberg*.

ALTONA, the most important city of the duchy of Holstein, North Germany, situated on the right bank of the Elbe, below and immediately adjoining Hamburg, and for commercial purposes forming with it a single town; pop. in 1871, 74,131. It is well built, is a free port, and enjoys privileges favorable to its trade and prosperity. It was set up by Denmark as a rival to Hamburg, and passed with Holstein into the possession of Prussia in 1867. It has six churches, a gymnasium with a library of upward of 20,000 volumes, an orphan hospital, an infirmary, a college, an observatory, and a mint. It has an extensive trade, and very considerable manufactories. The chief manufacture is tobacco. There are also soap and oil works, sugar houses, distilleries, chemical works, rope walks, tanneries, and divers manufactories of cotton, silk, and leather. Its extensive railway and steamboat connections add materially to its importance. Altona was burned by the Swedes, under General Steenbock, in January, 1713, with circumstances of great barbarity.

ALTOONA, a city of Blair co., Penn., 244 m. by railroad W. N. W. of Philadelphia, and 115 m. E. of Pittsburgh; pop. in 1860, 3,595; in 1870, 10,610. It was laid out in 1849, and is situated at the head of Tuckahoe valley and at

the foot of the Alleghenies. It is on the line of the Pennsylvania central railroad, to which it owes most of its prosperity; the workshops of the company situated here are the most extensive in the state. The city contains 11 churches, a high school, 2 banks, 6 hotels, and 3 daily newspapers. At Altoona the western-bound traveller begins the ascent of the Alleghenies. In the course of the next 11 m. some of the finest views and the greatest achievements of engineering skill on the entire line are to be seen. Within this distance the road reaches the summit by so steep a grade that, while in the ascent double power is required to move the train, the entire 11 m. of descent are run without steam, the speed of the train being regulated by the brakes. The summit of the mountain is pierced by a tunnel 3,670 feet long. On the eastern slope is the famous "horse-shoe bend," formed by a very short curve in the road around the brink of a precipitous descent.

ALTORF, or **Altdorf**, capital of the canton of Uri, Switzerland, in a deep, narrow valley on the Reuss, near the S. E. extremity of Lake Lucerne, at the N. E. terminus of the St. Gothard road; pop. in 1870, 2,724. It is neatly built, and has a Capuchin convent and an old tower covered with paintings in honor of William Tell, which is popularly believed to occupy the spot where he shot the apple from his son's head, though recent research has proved it to be of a date anterior to the time in which that hero of the Swiss legends figures.

ALTO-RILIEVO, a term designating that species of sculpture in which the figure stands completely out from the ground, being attached to it only in some places, and in others worked entirely round like single statues; such are the metopæ of the Elgin marbles in the British museum. Donatelli's alti-rilievi at Florence are among the most perfect examples of this sort of art. The largest work ever executed in alto-rilievo is that by Algardi in St. Peter's at Rome, representing the repulse of Attila by St. Peter and St. Paul.

ALTURAS, a S. county of Idaho, bordering on Montana, and bounded S. and S. E. by Snake river; pop. in 1870, 689, of whom 314 were Chinese. The Salmon river, a branch of the Columbia, is the principal stream. The N. part of the county is occupied by the Rocky mountains. There are 9 quartz mills.

ALUM, a name given to a remarkable series of double salts, of which potash alum may be taken as the type. The alums are more or less soluble in water, crystallize in regular octahedra, and differ from the normal compound in the fact that the alumina and potash are replaced in whole or in part by their isomorphs. We can replace the alumina by the sesquioxide of iron, of manganese, or of chromium, and the potash by soda, the oxide of ammonium, the oxides of ammonium compounds, the oxides of rubidium, cesium, and thallium. Lithia is the only one of the alkalis that does not form

an alum. Selenic acid, isomorphous with sulphuric acid, and (it is believed) telluric acid, can be substituted for sulphuric acid in the composition of alums. The following is a list of alums actually known to chemists, together with their chemical formulas: 1. Ordinary potash alum, $(\text{SO}_4)_3\text{Al}_2 + \text{SO}_4\text{K}_2 + 24\text{H}_2\text{O}$. 2. Soda alum, $(\text{SO}_4)_3\text{Al}_2 + \text{SO}_4\text{Na}_2 + 24\text{H}_2\text{O}$. 3. Ammonia alum, $(\text{SO}_4)_3\text{Al}_2 + \text{SO}_4(\text{NH}_4)_2 + 24\text{H}_2\text{O}$. 4. Rubidium alum, $(\text{SO}_4)_3\text{Al}_2 + \text{SO}_4\text{Rb}_2 + 24\text{H}_2\text{O}$. 5. Cæsium alum, $(\text{SO}_4)_3\text{Al}_2 + \text{SO}_4\text{Cs}_2 + 24\text{H}_2\text{O}$. 6. Thallium alum, $(\text{SO}_4)_3\text{Al}_2 + \text{SO}_4\text{Tl}_2 + 24\text{H}_2\text{O}$. 7. Manganese alum, $(\text{SO}_4)_3\text{Mn}_2 + \text{SO}_4\text{K}_2 + 24\text{H}_2\text{O}$. 8. Chrome alum, $(\text{SO}_4)_3\text{Cr}_2 + \text{SO}_4\text{K}_2 + 24\text{H}_2\text{O}$. 9. Chrome-ammonium alum, $(\text{SO}_4)_3\text{Cr}_2 + \text{SO}_4(\text{NH}_4)_2 + 24\text{H}_2\text{O}$. 10. Iron alum, $(\text{SO}_4)_3\text{Fe}_2 + \text{SO}_4\text{K}_2 + 24\text{H}_2\text{O}$. 11. Iron-ammonium alum, $(\text{SO}_4)_3\text{Fe}_2 + \text{SO}_4(\text{NH}_4)_2 + 24\text{H}_2\text{O}$. 12. Thallium-iron alum, $(\text{SO}_4)_3\text{Fe}_2 + \text{SO}_4\text{Tl}_2 + 24\text{H}_2\text{O}$. 13. Selenic alum, $(\text{SeO}_4)_3\text{Al}_2 + \text{SeO}_4\text{K}_2 + 24\text{H}_2\text{O}$. To this list may be added alum of trimethylamine, alum of ethylamine, alum of methylamine, and alum of amylamine.—The history of alum dates back to a remote antiquity. Pliny in his *Historia Naturalis* mentions several kinds of *alumen*, and says that a black and a white occur in Cyprus, the former being used for dyeing dark wool and the latter for light fabrics. As he afterward says that *alumen liquidum* is colored black by nut galls, he either refers to an impure alum or confounds the substance with sulphate of iron or green vitriol. It is, however, safe to assume that the *στυπτηρία* of the Greeks and the *alumen* of Pliny have reference to impure varieties of what is now called alum. It was manufactured some centuries since at Ræca in Mesopotamia, whence Leibnitz traced the name *alumen roccæ*, or rock alum. In the 13th century the business was established near Smyrna, and in 1248 extended to Italy, where it was protected against foreign importations by the pope. From thence it spread over Germany, and in the reign of Queen Elizabeth was undertaken in England by Thomas Chaloner, and successfully prosecuted notwithstanding the anathemas of the pope. At first only potash alum was manufactured, but since the introduction of ammonia as a refuse product in the production of illuminating gas large quantities of ammonia alum have been made. The more recent development of the potash deposits of the Stassfurt mines has again brought back the production of potash alum to the first rank, and its manufacture is now conducted on an immense scale.—Potash alum occurs ready formed in nature, especially among volcanic rocks near Naples, on the Rhine, on the island of New York, and in numerous other localities. Where the quantity is sufficient to pay for the trouble, the decomposed rock is leached and the resulting liquor left to crystallize; but only a very small proportion of the alum of commerce is obtained in this way. There are three classes of raw material from which potash alum is manufactured:

1. Such as contain the constituents of alum in the native state; *e. g.*, native alum, alum stone, alum slates.
2. Such as only contain sulphate of alumina, and require the addition of an alkali; *e. g.*, a majority of the alum slates, alum earths, clay, and pyritous bituminous shales.
3. Such as only contain the alumina and require the addition of both the sulphuric acid and the alkali; *e. g.*, clay, cryolite, bauxite, and feldspar. By far the greater proportion of alum is made from alum earths and shales, although the employment of clay, cryolite, and feldspar is on the increase. The mineral alum stone or alunite forms seams in trachytic and allied rocks, where it has been formed as a result of the alteration of the rock by means of sulphurous vapors. It is met with at Tolfa near Civita Vecchia, at Montioni in Tuscany, in Hungary, and in other localities. The compact varieties of Hungary are so hard as to admit of being used for mill-stones. It was first observed at Tolfa in the 15th century, by J. de Castro, a Genoese, who had been engaged in the manufacture of alum from an alum stone or "rock alum" found near the Euphrates. The composition of alunite is very variable. One specimen from Tolfa was found to contain sulphuric acid 35.50, alumina 39.65, potash 10.02, and water 14.83. It is only when the alunite has been heated to 450° C. that the alum can be extracted from it by water. The stone is roasted in heaps on calcining kilns until it begins to give off sulphurous acid fumes, when the operation is suspended. The calcined material is then placed in troughs of masonry and sprinkled with water until it forms a slimy paste; this is leached in shallow pans with hot water, the lye concentrated and crystallized. Roman alum has a reddish hue, and has long been preferred on account of its freedom from soluble foreign substances. Much of what is now called Roman alum is colored red by the addition of brick dust. Most of the alum of commerce is made by the calcination of aluminous schists, which are argillaceous rocks, containing considerable quantities of sulphide of iron. This is converted by exposure to the air into ferrous sulphate and free sulphuric acid, $\text{FeS}_2 + \text{O}_7 + \text{H}_2\text{O} = \text{FeSO}_4 + \text{H}_2\text{SO}_4$; and the sulphuric acid, acting on the alumina contained in the clay, forms sulphate of aluminium. These aluminous schists are found in two different geological positions, *viz.*: in the transition strata (alum slate), in which position they are largely impregnated with bitumen; and in the lower tertiary strata, just above the chalk (alum earth). The latter are much less compact than the former; consequently their oxidation is easier, and sometimes takes place spontaneously.—The most extensive alum manufactory in Great Britain (1871) is at Hurlett, near Paisley. The next in magnitude is at Whitby, of whose state and processes an instructive account was published by Mr. Winter in the 25th volume of "Nicholson's Journal." The stratum of aluminous schist is about 29

miles in width, and is covered by strata of alluvial soil, sand-stone, ironstone, shell, and clay. The alum schist is generally found disposed in horizontal laminae. The upper part of the rock is the most abundant in sulphur, so that a cubic yard taken from the top of the stratum is five times more valuable than the same bulk 100 feet below. If a quantity of the schist be laid in a heap and moistened with sea water, it will take fire spontaneously, and continue to burn till the whole inflammable matter is consumed. Its color is bluish gray; sp. gr. 2.48. It imparts a bituminous principle to alcohol. The rock, broken into small pieces, is laid on a horizontal bed of fuel, composed of brush-wood, &c. When about four feet in height of the rock is piled on, fire is set to the bottom, and fresh rock continually poured upon the pile, until the calcined heap is raised to the height of 90 or 100 feet. Its horizontal area is at the same time progressively extended, till it forms a great bed nearly 200 feet square, having about 100,000 yards of solid measurement. The rapidity of the combustion is allayed by plastering up the crevices with small schist moistened; but notwithstanding this precaution, a great deal of sulphuric or sulphurous acid is dissipated. One ton of alum is produced from 130 tons of calcined schist; this result has been deduced from an average of 150,000 tons. The calcined mineral is digested with water in pits usually containing about 60 cubic yards. The liquid is drawn off into cisterns, and afterward pumped up again upon fresh calcined "mine." This is repeated until the specific gravity becomes 1.15. The half exhausted schist is then covered with water to take up the whole soluble matter. The strong liquor is drawn off into settling cisterns, where the sulphate of lime, iron, and earth are deposited. At some works the liquid is boiled, which aids its purification. It is then run into leaden pans 10 feet long, 4 feet 9 inches wide, 2 feet 2 inches deep at one end, and 2 feet 8 inches at the other. This slope facilitates the emptying of the pans. Here the liquor is concentrated at the boiling heat. Every morning the pans are emptied into a settling cistern, and a solution of chloride of potassium (either pretty pure from the manufacturer, or the crude compound from the soap boiler) is added. The quantity of chloride necessary is determined by a previous experiment in a basin, and is regulated for the workmen by the hydrometer. By this addition, the pan liquor, which had acquired a specific gravity of 1.4 or 1.5, is reduced to 1.35. After being allowed to settle for two hours, it is run off into the coolers to be crystallized. At a greater specific gravity than 1.35, the liquor, instead of crystallizing, would on cooling solidify in a magma resembling grease. After standing four days, the mother waters are drained off, to be pumped into the pans on the succeeding day. The crystals of alum are washed in a tub and drained. They are then put into a lead pan,

with as much water as will make a saturated solution at the boiling point. Whenever this is effected, the solution is run off into casks. At the end of 10 or 16 days the casks are unhooped and taken asunder, when the alum is found exteriorly in a solid cake, but in the interior cavity in large pyramidal crystals, consisting of octahedrons, inserted successively into one another. This last process is called "rocking." Mr. Winter says that 22 tons of chloride of potassium, or an equivalent of 31 tons of the black ashes of the soap boiler or 73 of kelp, will produce 100 tons of alum. Where much iron exists in the alum ore, the alkaline chloride, by its decomposition, gives rise to an uncrystallizable chloride of iron. For this reason it is preferable to the sulphate of potassium. —Alum may also be obtained from cryolite by heating the mineral with three times its weight of strong sulphuric acid, whereby anhydrous neutral sulphate of aluminum and acid sulphate of sodium are obtained; treating the resulting mass with a small quantity of cold water to remove the acid sodium salt; then digesting the anhydrous sulphate of aluminum with warm water, to convert it into the hydrated salt, and adding the proper quantity of sulphate of potassium. As the alum from cryolite is remarkably free of iron, it is highly prized by many manufacturers. —The discovery of an aluminous earth in the neighborhood of Baux, France, and hence called bauxite, has added to the class of materials for the manufacture of alum. To this the addition both of sulphuric acid and of a salt of potash is necessary. Bauxite is extensively employed in the manufacture of the sulphate of alumina (alum cake) and of the metal aluminum. —At the chemical works of Harrison Brothers, Philadelphia, ammonia alum is manufactured from a pure clay mostly obtained from New Jersey. The clay is dried and then ground and calcined in a reverberatory furnace. When thoroughly calcined and purified, it is while hot digested for some hours in sulphuric acid contained in large vats. The product is washed with water and concentrated, sulphate of ammonia having been previously introduced, and it is further purified by redissolving, then boiled by steam, and finally transferred to the crystallizing tubs. These are about eight feet high, and made of strong staves. At the end of eight or ten days, the staves of the tub being removed, a cylindrical mass of apparently solid alum is revealed. This being pierced near the bottom, the mother water at the centre flows off along the sloping floor into leaden subterranean cisterns, whence it is subsequently pumped and variously utilized. Each crystallizing vat yields about 21 barrels of alum ready for market. —The composition of pure potash alum is:

Potash.....	per cent.	9.89
Alumina.....	"	10.94
Sulphuric acid.....	"	33.65
Water.....	"	45.49
		100.00

or,

Sulphate of potash.....	per cent.	18.81
Sulphate of alumina.....	"	36.21
Water.....	"	45.48
		100.00

Its specific gravity is 1.724. It is soluble in 18 parts cold water and in equal weight of boiling water. It consequently rapidly crystallizes out of a hot saturated solution. Alum has a sweet astringent taste, an acid reaction, and, like sulphuric acid, dissolves many metals, for example iron and zinc, with evolution of hydrogen gas.—Burnt alum, or dried alum, is made by gently heating alum till the water is driven off. Ammonia alum readily loses all its ammonia when heated, and the sulphuric acid may be driven off the remaining sulphate, so that the pure earth alumina will remain.—The employment of alum in medicine and the arts is very extensive. It precipitates albuminous liquids and combines with gelatine. It causes dryness of the mouth and throat, and checks the secretions of the alimentary canal, producing constipation, and in large quantities nausea, vomiting, and purging. Its principal use is in dyeing. The goods are mordanted with it and put in the dye, when the colors are precipitated and fixed in the texture of the cloth by the alumina. Alum is added to the size in the manufacture of paper to prevent decomposition, and also to bookbinders' paste for a similar purpose. Baths of alum are used in the tanning of leather, and it is applied in the printing baths of photographers. It has also been employed in refining sugar and in the manufacture of pigments called lakes. The leather of Hungary is made by impregnating strong hides with alum, common salt, and suet; and in the coloring of morocco the puce tint is communicated by logwood with a little alum. When alum is added to tallow, it makes it harder. Printers' cushions and the blocks used in the calico manufactory are rubbed with burnt alum to remove any greasiness which might prevent the ink or color from adhering. Water can be purified by means of alum; the mud that water holds in suspension collects on the addition of 0.001 part of alum (this is equal to seven grains per gallon) in long thick streaks, coagulates as it were, and is immediately precipitated. This process, the principle of which is inexplicable, was first introduced by the Chinese, and has been imitated in various parts of the world. The operation was well known from a very early period in the highlands of Scotland, according to Dr. Clark, where it is practised with peat water. The Parisian laundresses use it, but it has not been introduced into any of the establishments for the purification of drinking water, partly because alum is a substance never naturally combined in water, and may be received as a real impurity, and partly on account of public prejudice. In bottling fruits for preservation, alum water is used. A novel application of alum is seen in the lining of some iron safes with a mixture of alum and

sulphate of lime; as the alum contains 24 equivalents of water, when the safe is heated it keeps the sides cool from the evaporation of the water, the contents of the safe remaining uninjured. It is used in the manufacture of bread to increase the whiteness of the flour. According to Liebig, this is very injurious, as he supposes the soluble phosphates to combine with the alumina, forming insoluble salts, and the beneficial action of the phosphorus is lost to the system. In the manufacture of hard alum is used as an adulterant. Dr. Hassall says that alum is generally put into the vat in breweries to give the beer a smack of age; it also imparts a heading to porter, which landlords are so anxious to raise to gratify their customers. Alum dissolved in water is used in the adulteration of gin; and it is added to artificial port wine, to increase the brilliancy of the color.

ALUMINA, the only known oxide of aluminum. It occurs colorless as corundum, and colored by traces of oxide of chromium and cobalt in the ruby and sapphire. It is found in a few places in larger quantities in the form of emery, which is nearly pure alumina. It is very widely disseminated in nature in combination with other bases in the form of double silicates, constituting feldspars, micas, and a large series of important minerals, from the decomposition and disintegration of which clays are composed. It forms the greater portion of the crust of the earth, and, in the form of clay, affects the fertility of every soil. It is not taken up by plants, except in rare cases, nor is it found in the animal kingdom. There has recently been discovered a mineral in the vicinity of Baux, France, to which is applied the name bauxite. It differs materially from clay in being simply a hydrated oxide of alumina and iron without any silica. It is entirely infusible, and crucibles and fire brick made of it remain unchanged when ordinary fire-clay material loses shape and partially fuses. It is extensively employed in the manufacture of sulphate and other salts of alumina, and of the metal aluminum. When perfectly pure, bauxite is composed of sesquioxide of alumina 52.00, sesquioxide of iron 27.60, and water 20.40; but its composition varies considerably, and some varieties contain small quantities of silica and lime. It differs especially from kaolin in not being a silicate but an oxide of alumina. Well known minerals analogous to it are gibbsite and diaspore.—Alumina may be prepared by adding ammonia to any of its soluble salts (alum for instance), when a gelatinous precipitate of the hydrate of alumina is thrown down, having the formula, according to the present chemical theories, of $Al_2H_6O_6 = Al_2O_3 \cdot 3H_2O$, after being dried in the air. To obtain it more dense and free of iron, it is now customary to pass carbonic acid gas through a dilute and cold solution of aluminate of soda, prepared in the United States from the mineral cryolite, which is brought from Greenland to be used in the manufacture of

glass and soap. The pure anhydrous alumina is prepared by the calcination of the hydrated oxide obtained as above described, or by exposing ammonia alum to a lively red heat. A peculiar modification of alumina is obtained, according to Walter Crum, by long-continued boiling of acetate of alumina: the acetic acid is liberated, and there remains a hydrated oxide soluble in water. A second modification of soluble alumina was discovered by Professor Graham, which can be obtained by the dialytic decomposition of a solution of hydrate of alumina in chloride of aluminum: it has properties differing from either of the other forms.—*Properties of alumina.* When pure it is a white, light powder, devoid of taste and odor, infusible excepting before the oxyhydrogen blow-pipe, when it constitutes a viscous fluid that can be drawn in strings like melted quartz, and on cooling yields a crystalline mass sufficiently hard to scratch and cut glass. Calcined alumina is absolutely insoluble in water, but if it has not been heated to redness it combines with a certain portion of water with disengagement of heat. Hydrated alumina is white when moist, but becomes translucent by desiccation, and sometimes yellow if it has been precipitated in the presence of organic matter. Its affinity for coloring matter is so great that it readily absorbs the organic dyes from solutions, and has extensive application as a mordant, as a clarifying agent, and in the manufacture of lakes. The hydrate of alumina after calcination is soluble only with difficulty in acids, but readily soluble when freshly precipitated. The hydrates, prepared according to the methods of Crum and Graham, are soluble in water and possess characteristic properties. Several of the metallic oxides, as soda and potash, if fused in a silver crucible with alumina, combine with it and form aluminates. The minerals corundum, sapphire, and ruby have been made artificially by Deville and Caron, by heating the fluoride of aluminum in a carbon crucible, underneath which is suspended a platinum capsule containing boric acid; at an elevated temperature the fluorine reacts on the boric acid and yields a fluoride of boron and a crystalline metallic oxide. By adding variable quantities of sesquioxide of chromium, good imitations of the ruby, sapphire, and corundum can be obtained; and it is said that Bonsdorf has made the mineral gibbsite by exposing a solution of aluminate of potash to the action of an atmosphere of carbonic acid. When metallic aluminum is heated to redness in the air or in oxygen gas, it burns brightly and is converted into alumina, 53.3 parts of the metal taking up 46.69 parts of oxygen to form the pure earth. The compound thus produced is inferred to be sesquioxide because it is isomorphous with the sesquioxides of iron and chromium, and is capable of replacing these oxides in combination in any proportion.

ALUMINUM, or *Aluminium*, one of the metals of the earths never found native, but occurring

in combination with other elements in 195 different species of minerals, and consequently constituting a large part of the solid crust of the earth. Among the minerals and rocks containing this metal may be mentioned the following: ruby, sapphire, corundum, emery, gibbsite, bauxite, turquoise, lapis lazuli, topaz, cryolite, feldspar, clay, and slates. Although so abundant, it is only within a few years that the metal has been prepared in a free state, and even at the present time the manufacture is too expensive to admit of its common use in the arts. Davy, Berzelius, and Oersted attempted to decompose the oxide by means of the electric current, but without success. Oersted, who discovered the chloride, failed in his efforts to decompose this salt by metallic alkalis. It was first prepared in 1827 by Wöhler, who obtained a gray metallic powder on decomposing the chloride with potassium under a gentle heat. In 1845 Wöhler obtained it in the form of a metallic button by passing vaporized chloride of aluminum over heated potassium. Its chemical and physical properties were then determined, and the subject allowed to rest till 1854, when it was a second time discovered by Deville. He heated the crude chloride of aluminum in an upright iron cylinder, connected by a pipe with a smaller horizontal cylinder containing iron nails, which reduced any perchloride of iron present to the less volatile protochloride, and also detained any hydrochloric acid or chloride of sulphur present. The vapor of aluminum chloride passed next through a long wrought-iron cylinder containing three dishes holding a pound of sodium each, and heated on the lower side to dull redness. The reaction is sometimes so violent as to require a careful regulation of the heat. Metallic aluminum is formed along with the double chloride of sodium and aluminum. This mass is then heated in an iron vessel or clay crucible until it is entirely melted and the double salt begins to evaporate. When cold the chloride of sodium found on top is removed, the buttons of aluminum are washed with water, dried, and heated to redness, when they may be pressed together. The loss of aluminum by this process is very considerable. The method was afterward abandoned, and the following mixture employed: chloride of aluminum and sodium, 400 grammes; common salt, 200; fluor spar, 200; sodium, 75 to 80. The double salt is previously fused and heated almost to redness, the common salt fused or strongly ignited, the fluor spar powdered and well dried. The double salt and common salt are broken up into a coarse powder, mixed with the fluor spar, and placed in a crucible with alternate layers of sodium, the whole being covered with a layer of common salt. It is heated gently at first, then more strongly, until the melting point of silver is nearly but not quite reached. The mass is stirred with a clay pipe stem, and poured out on a dry slab of limestone. The aluminum is readily separated

from the slag, and should yield 25 grammes from 75 grammes of sodium. In this experiment the fluor spar should be free from silica, and the sides of the crucible be protected by a layer of alumina prepared from a paste of 4 parts ignited aluminum and 1 part aluminate of lime. The process requires some experience in order to succeed. It is much easier and simpler to employ cryolite instead of fluor spar. In 1855 H. Rose in Berlin, and Dr. Percy in England, prepared aluminum from cryolite. The pulverized mineral was mixed with half its weight of common salt, and the mixture arranged in alternate layers with sodium (2 parts sodium to 5 parts cryolite), in an earthen or iron crucible covered with a layer of pure cryolite, and the whole covered with common salt. The crucible, well covered, is heated to a bright red heat by means of a blast lamp for half an hour, then allowed to cool, and the contents removed with a chisel, at the same time tapping the crucible with a hammer. In 1858 Gerhard invented and patented an improvement, consisting in the use of a reverberatory furnace with two hearths, one above the other, communicating by an iron pipe. In the lower is placed the mixture of sodium with the aluminum compound, and in the upper a stratum of common salt, or of a mixture of sodium and cryolite, or of the slag from a former operation. This layer when melted is made to run into the lower furnace in quantity sufficient to cover completely the mixture contained therein, so as to protect it from the air.—Several attempts have been made, but with doubtful success, to separate aluminum from its compounds by means of the ordinary reducing agents, hydrogen and carbon. Johnson has patented the following process: Mix together sulphide of aluminum and anhydrous sulphate of aluminum, in such proportions that the oxygen present is just sufficient to convert all the sulphur into sulphurous acid ($Al_2S_3 + Al_2(SO_4)_3 = 4Al + 6SO_2$). The mixture is heated in a non-oxidizing atmosphere to a red heat. Corbelli of Florence mixes the impure sulphate with 2 parts ferrocyanide of potassium and $1\frac{1}{2}$ of common salt, heating the whole to redness. Knowles decomposes the chloride by means of cyanide of potassium. Bunsen in 1854 obtained aluminum by electrolysis of the fused chloride of aluminum and sodium in a red-hot crucible, ten elements of a Bunsen battery being required. Messrs. Bell Brothers of England commenced producing aluminum a few years since from the ammonia alum of commerce, but afterward employed a native hydrated oxide known as the mineral bauxite. (See ALUMINA.) The bauxite, having first been reduced to fine powder by grinding under an edge-stone, is mixed with a quantity of soda slightly more than is necessary to form aluminate of soda with the alumina of the mineral, and heated in a reverberatory furnace. The aluminate of soda thus produced is afterward decomposed, and furnishes

the alumina for further decomposition by means of chlorine and sodium as above described. The electro-galvanic deposition of aluminum, although frequently attempted, does not appear to have been successfully accomplished.—*Properties of aluminum.* Aluminum is a bluish white metal, without odor or taste, nearly as malleable as gold and silver; density of the fused metal 2.50, of the hammered 2.67; melting point between that of silver and zinc; nearly as good a conductor of electricity as silver; does not oxidize in the air, even at a strong red heat; does not decompose water excepting at a white heat; is not blackened by sulphuretted hydrogen. It is not attacked by nitric acid, either dilute or concentrated, at ordinary temperatures, and very slowly even at the boiling heat; neither is it acted upon by sulphuric acid diluted to the degree at which that acid dissolves zinc; but hydrochloric acid, either dilute or concentrated, dissolves it easily even at low temperatures, with evolution of hydrogen. Caustic soda and potash readily dissolve it, forming aluminates of those bases. Ammonia acts but slightly on it. Professor Würtz of New York prepares an amalgam of aluminum by heating thin foil on mercury in a glass tube so drawn out that the foil cannot swim on the mercury. This amalgam is more readily decomposed in the air and in water than sodium amalgam. Aluminum is a powerful reducing agent for solutions of chlorides, and in the preparation of the rare elements boron and silicon. An alloy of aluminum with silver, called third silver (*tiers-argent*), composed of one third silver and two thirds aluminum, is chiefly employed for forks, spoons, and tea service, and is harder than silver and more easily engraved. Another alloy, called *minargent*, is composed of 100 parts copper, 70 parts nickel, 5 parts antimony, and 2 parts aluminum. The beautiful tone of the metal has suggested its use in the manufacture of bells, and a successful application of it for this purpose has been made. Mixed with copper in the proportion of 10 parts of aluminum and 90 of copper, it forms a beautiful alloy known as aluminum bronze, now frequently employed for the manufacture of watch cases, watch chains, imitation jewelry, sheathing for stairs, and bearings of machinery. The alloy of aluminum with iron is crystalline and of no value in the arts. Experiments made in 1865 at the United States mint on alloys of aluminum for coins were not sufficiently successful to induce the government to adopt them. The difficulty encountered in soldering and welding aluminum, and the high cost of its production, have seriously interfered with its extensive application in the arts. It can hardly be said to have fulfilled all the expectations that were raised at the time of the revival in its manufacture introduced in 1855 by Deville.—*Salts of aluminum.* These are very numerous, many of them extensively employed in the arts. Alum and the oxide alumina are separately de-

scribed. The chloride, Al_2Cl_6 , can be prepared by passing dry chlorine gas through a heated mixture of alumina and charcoal. It is a volatile compound, and is used as above described in the manufacture of the metal aluminum. The hydrated chloride of alumina is easily prepared by dissolving aluminum in hydrochloric acid. It is sold in commerce, under the name of chloralum, as a disinfectant and antiseptic, and is also recommended for salting paper in photography. Sulphate of aluminum is known in a crude state as alum cake, and is prepared on a large scale by roasting aluminous shales as described under ALUM. It can be prepared in a small way by dissolving the hydrate of alumina in sulphuric acid. Acetate of aluminum is prepared by precipitating acetate of lead with sulphate of aluminum or with a solution of alum. It is extensively used as a mordant in calico printing, especially in producing madder reds, whence it is called "red liquor."

ALUMNUS (Lat., from *alere*), to nourish, originally the designation of a student who was supported and educated at the expense of the *alumnat*, an institution which, especially after the reformation, was endowed for the particular purpose of extending hospitality and education to youths who could not afford to pay for their living and tuition. Maurice of Saxony endowed three such institutions in Pforte, Meissen, and Grimma, which are to this day in active operation. The alumni have to adhere to the rules of the establishment and to perform various services for the school and the church, such as singing in the choir and the like, while the *extraneers*, the name given to students who pay for their board and tuition, are not bound to perform such services. In ordinary parlance, every graduate of a university or college is now an alumnus.—In jurisprudence, the term *alumnat* is the generic expression for the general responsibilities attached in the eyes of the law to the relationship of the foster-father (*nutritor*) toward the child whom he has undertaken to support and educate.

ALUNNO, Nicolò, of Foligno, an Italian painter of the 15th century, one of the masters of the Umbrian school, which was the forerunner of the Roman. His earliest known work bears the date of 1458, and his latest that of 1499. His *Pietà* in the cathedral of Assisi, of which only a portion remains, was regarded by Vasari as his master work. His other works are chiefly found in Perugia and Foligno.

ALFRED, Alred, or Alfred of Beverley, an English historian, died probably in 1129. He is said to have been a native of Yorkshire and one of the canons and treasurer of the church of St. John in Beverley. He left an "Epitome of British History" from the time of the fabulous Brutus to the 29th year of Henry I., written in good Latin, and compiled with a care unusual for that day. It was published by Hearne at Oxford in 1716. The work bears a strong resemblance to that of Geoffrey of Mon-

mouth, both having probably been drawn from the same sources.

ALUTA, Alt, or Olt, a northern affluent of the Danube, which rises in the Carpathians of eastern Transylvania, and, after flowing S. and then W., crosses the Carpathians S. of Hermannstadt, traverses Wallachia, and empties near Turna, opposite Nicopolis. Its entire course is about 330 m. Its principal tributary is the Oltetz, in Wallachia.

ALVA, or Alba, Fernando Alvarez de Toledo, duke of, a Spanish general and statesman, born in 1508, died Jan. 12, 1582. He was descended from a family which boasted its extraction from Byzantine emperors; and one of his ancestors, a Palæologus, conquered Toledo, and transmitted its appellation as a family name. From his earliest years he was trained to arms, and imbibed a hatred of infidels, which was afterward naturally transferred to those at enmity with the church of Rome. At 16 years of age he fought at Fontarabia, and in 1530 he accompanied the emperor Charles V. in his campaign against the Turks. At this period he seemed like one of the romantic heroes of chivalry. On one occasion he rode as fast as his steed could bear him from Hungary to Spain and back again, merely for a hurried visit to his young bride. In 1535 he took part in Charles's expedition to Tunis. In 1546-7 he was generalissimo in the war against the Smalcaldian league, winning his greatest honors at the battle of Mühlberg, in which he totally routed the Protestant forces. In 1554 he went with the Spanish crown prince to England, and shortly before that prince's accession to the throne as Philip II. on the abdication of Charles V. was made generalissimo of the army in Italy, engaged in a war with Pope Paul IV. Although he revered the successor of St. Peter, he was greatly displeased with Philip for obliging him to make peace with the pontiff, whose capital he had seized. To patience and cunning he united ferocity and a thirst for blood scarcely human; he hardly knew the meaning of pity, though frequently alluding to his clemency in his letters to Philip. The personal appearance of this extraordinary man well merits description. He was tall, thin, erect, with a small head, dark sparkling eyes, cavernous cheeks, and a stern expression, rendered more striking by a long, thin, waving, and silvered beard. In manners he was cold and haughty, and was even more inaccessible than his royal master. The spoliation of the churches in the Netherlands by the iconoclasts had enraged Philip more than any of the other troubles in his Flemish provinces; and their armed invasion having been determined on, 10,000 picked veterans were placed under the command of the duke of Alva. Refused a passage through the French dominions, the force embarked at Cartagena, May 10, 1567, and landed at Genoa. The whole army was under the most perfect discipline, and attached to it was a force of 2,000 prostitutes, enrolled and distributed,

doubtless to prevent the troops from any outrages in lands through which lay their march. In three divisions they made their way over Mont Cenis, and through Savoy, Burgundy, and Lorraine, and without the least opposition entered the territory of the Netherlands. Great was the alarm in the disaffected provinces when it was learned that Alva was on his march. William of Orange, who was not to be deceived by any show of clemency, had retired into Germany. The duke's interviews with the duchess of Parma, then regent of the Netherlands, were brief and formal; but in spite of courtly etiquette, neither could well conceal dislike of the other. Margaret, enraged at being superseded, soon took her departure, and Alva was left alone to fulfil his mission. Establishing his headquarters at Brussels, he at once proceeded in his work of vengeance. The "Council of Troubles" was set up, to inquire into and punish all past offences; and so merciless were its labors, that it was styled by the populace the council of blood. Counts Egmont and Horn, the two idols of the people, who had been foremost in asserting the religious liberties of the Netherlands, but who were guilty of no treason, were beheaded in the great square of Brussels, June 5, 1568. The execution of other popular leaders immediately followed; burnings at the stake and decapitation thenceforth were decreed by wholesale, and during the whole period of Alva's six years' administration in the Netherlands blood flowed like water. Throughout the land his name, and those of his terrible subordinates in the blood council, Hessel and Vargas, came to be feared and hated. The least suspicion of any person, however innocent, especially if he was rich, drew down the vengeance of the council; for Alva had promised before he left Spain to enrich the treasury of Philip by a golden river a yard deep, drawn from the confiscated wealth of heretics; he even named 500,000 ducats per annum as the sum. Military operations had begun before the fatal 5th of June. Count Louis of Nassau having invaded Friesland, Alva took measures to oppose him vigorously. At first the count met with some success, and at the battle of Heiligerlee defeated the Spaniards under the duke of Arceberg, who was killed. Alva was roused to fury at the news, and to expiate the loss of the duke beheaded 18 nobles besides hastening the execution of Egmont and Horn, and then left Brussels to meet the count in the field. An attempt to destroy the dikes and inundate the country was frustrated by the arrival of Alva's forces, and at the battle of Jemmingen he utterly routed Louis and destroyed his army. William of Orange persevered, and, mustering another army, sought in vain to bring Alva to an engagement. Twenty-nine times did the prince change his encampment, and as often did the Spanish forces hover in his rear. The duke's skill in the campaign of 1568 was a masterpiece of tactics; he had no-

thing to gain, the prince everything to hope for, by a battle. The country people of Brabant, the scene of this masterly inactivity, refused the prince supplies; and Alva had caused the irons to be taken out of every mill, so that not a bushel of corn could be ground in the province. Frustrated in his hopes of a battle, William was further dejected by the supineness of the country. Not a single city opened its gates to him; he was forced to quit the Netherlands and disband his army soon after, while Alva erected a colossal bronze statue of himself in the citadel of Antwerp, and ordered a series of magnificent fêtes to be celebrated at Brussels. He was soon engaged in a quarrel with Elizabeth of England, who had seized in her ports \$800,000 of Spanish funds. Alva retaliated by ordering the arrest of every Englishman in the Netherlands, and the seizure of all their property; and between the two angry spirits, Flemish prosperity was well nigh annihilated. But the duke was disappointed in his hopes of forcing a golden stream to flow into the king's coffers; with all his abilities as a soldier, he was a wretched financier; and so far from supporting his army on the confiscations of the people, and supplying Philip with gold besides, as he boasted he would, during the six years of his rule twenty-five millions of money were sent to him from Spain, yet he left the Netherlands without a dollar in the treasury. Among his odious schemes were a tax of the hundredth penny, or one per cent., on all property, real and personal, to be paid instantly and collected once; a perpetual tax of the twentieth penny, or 5 per cent., on every transfer of real estate; and a tax of the tenth penny, or 10 per cent., assessed upon every article of merchandise or personal property, to be paid as often as it should be sold. No sooner was this monstrous imposition declared than every one in the land excepting the duke himself perceived how utterly abortive and ridiculous a scheme it would prove. The towns rebelled, and examples by dozens were made of refractory citizens to no purpose. The king was petitioned, and finally, after all the severity of Alva, a temporary compromise was effected, by which the towns were to pay \$2,000,000 yearly for the two following years, that is, until the month of August, 1571. At length universal revolt was manifested. The shops were all closed; "the brewers refused to brew, the bakers to bake, the tapsters to tap." Alva thereupon resolved to hang 18 of the tradesmen of Brussels at the doors of their own shops, without trial. This summary work was prevented, however, by the news of the capture of Briel by the "Water Beggars," adherents of the prince of Orange. The revolution and capture of Flushing soon followed, and the first half of the year 1572 was distinguished by a series of triumphs for the patriot party. The nation shook off its fetters in one sudden bound of enthusiasm, and Oudewater, Dort, Leyden, Gorcum, Gouda, Horn, Alkmaar, Edam, and many

other towns, ranged themselves under the standard of the prince of Orange. His triumph, however, was short, for the news of the massacre of St. Bartholomew, in August, fell with frightful effect upon his followers, utterly paralyzing their hopes and efforts; his armies melted away, the towns forsook their allegiance to him, and almost in solitude he retired to Holland, the province which best preserved its fidelity. He had but a few days before considered Charles IX. of France as his ally, and was expecting an army of assistance led by Admiral Coligni, when he heard the news of his murder. On many of the offending cities, even those which returned to obedience, Spanish vengeance fell with terrible retribution. At length, at the siege of Alkmaar, after investing the city for seven weeks, the Spaniards were obliged to retreat; and from that moment a brighter day dawned on the Netherlands. Finally, disgusted with the hopelessness of his cause, and furious at the intrigues of those in power about him, Alva obtained his recall, received his successor, Don Luis de Requesens y Zuñiga, Nov. 17, 1573, and on the 18th of the next month left the provinces for ever. His parting advice was, that every city in the Netherlands should be burned to the ground, except a few to be permanently garrisoned; and he boasted that during his six years' rule he had caused 18,000 persons to be executed. But to this immense number must be added those who perished by siege, battle, and merciless slaughter; and the list defies all computation. Every conceivable mode of death and torture was wreaked upon the victims of his royal master's vengeance. At the sack of Haarlem 300 citizens, tied two and two and back to back, were thrown into the lake; and at Zutphen 500 more, in the same manner, were drowned in the river Yssel. Thousands of women were publicly violated, and unborn infants ripped from the wombs of their mothers. Yet Alva was always complaining to Philip II. of the unjust hatred shown toward him, and the "ingratitude" of the Netherlanders in return for his "clemency." He was well received by Philip II., but some time afterward fell into disgrace with the monarch, from espousing the cause of his own son, who had debauched a maid of honor. He was imprisoned and banished until required for the conquest of Portugal. This he accomplished in 1580, and died at the age of 74 years.

ALVAR, *Awur*, or *Machery*, a native state of Hindostan, in Rajpootana, between lat. 27° 4' and 28° 13' N., and lon. 76° 7' and 77° 14' E.; area, 3,573 sq. m.; pop. about 280,000. It is a hilly district, inhabited by a savage, predatory people known as Mewattis, and long famous for their hostility to Europeans. Under British influence, however, their rude character has been greatly modified. The state is governed by a rajah who is under the control of the governor general's agent for the Rajpoot states.—*Alvar*, the capital, is situated at the

base of a rocky range, 110 m. S. S. W. of Delhi and 900 m. N. W. of Calcutta. It is a small, ill-built town, surrounded by a wretched mud wall, and overlooked by a fort on the hill. The rajah's palace and some Hindoo temples are the principal buildings.

ALVARADO, a river and town in Mexico, in the state of Vera Cruz. The town is situated on the left bank of the river, about 3 m. from its mouth, and 35 m. S. E. of Vera Cruz; pop. about 2,000. It consists mostly of cane cottages roofed with palm leaves. The country south of the river has numerous plantations of cacao, and produces much rice, both of which articles are sent to the other states of Mexico. There is a dockyard at Alvarado, and a port capable of admitting vessels not exceeding 13 feet draught; and it has considerable commerce with Vera Cruz. The climate is very unhealthy.

ALVARADO, *Pedro de*, one of the conquerors of Spanish America, born at Badajoz toward the end of the 15th century, died in 1541. In 1518 he sailed with his four brothers for Cuba, whence he accompanied Grijalva in his exploring expedition along the coast of the American continent. Grijalva was so delighted with the aspect of the country that he called it New Spain, and sent Alvarado back to Cuba to report to Governor Velasquez what they had seen and what they had heard, for the first time, about the immense empire of Montezuma. In February, 1519, he accompanied Cortes in his expedition, and took an active and remarkable part in all the incidents of the conquest of Mexico. Cortes, while engaged in the battle against Narvaez, left the city of Mexico under charge of Alvarado, but by his cruelty and rapacity the latter caused an insurrection, and narrowly escaped with his life. In the famous retreat of the night of July 1, 1520 (*la noche triste*), Alvarado distinguished himself by his gallant exploits, and to commemorate his bravery an enormous ditch over which he leaped to escape from the hands of the enemy is called to this day "el salto de Alvarado." On his return to Spain he was received with great honor by Charles V., and appointed governor of Guatemala, which he had conquered in 1523. He married a daughter of the illustrious house of Cueva, from which the dukes of Albuquerque are descended, and returned to America, accompanied by a host of adventurers. Guatemala became highly prosperous under his government. Having authority to extend his conquests, he embarked on the Pacific an expedition of 500 men to effect the capture of Quito, and landed near Cape San Francisco, whence he marched into the interior; but among the Andes he met the forces of Pizarro, prepared to resist his advance. Disclaiming any intention to interfere with his countryman's rights, he received 120,000 pieces of eight as an indemnification for his outlay and losses, and, after a friendly meeting with the conquerors of Peru, returned to Gua-

temala. Visiting Spain soon afterward, he appeased the emperor's displeasure at this affair, obtained in addition to his former command the governorship of Honduras, and then fitted out from Guatemala a new expedition of discovery, consisting of 12 large ships, two galleys, 800 soldiers, 150 horses, and a large retinue of Indians. Sailing W. and N. W. along the Mexican coast, he was driven by stress of weather into the port of Los Pueblos de Avalos, in Michoacan. Here a messenger from the Spaniards of the interior asked his assistance in putting down a revolt of the Chichimecas of New Galicia. He landed with a part of his force, made a rapid march to the encampment of his countrymen, and with them attacked the Indians, who were strongly posted among the mountains. The Spaniards were defeated and put to flight, and Alvarado was killed by his horse falling upon him at the crossing of a river. The expedition was then abandoned.

ALVAREZ, Francisco, a Portuguese traveller, born in Coimbra, died after 1540. He was chaplain of King Emanuel, and in 1515 accompanied his embassy to the negus or emperor of Abyssinia, then known to the Portuguese as Prester John. Going first to India, they were delayed by various causes, among which was the death of the original ambassador, Duarte Galvam, and the substitution of Don Rodrigo de Lima, a soldier quite unfit for the charge. Landing at Massowah April 6, 1520, their journey through the interior was beset with many difficulties and dangers; but at last, on Oct. 20, they were received at the temporary court of the negus, an encampment in Shoa. Alvarez made himself acceptable to all parties, especially to the Abyssinian priesthood, who respected his religious character, and to the negus, who conceived such admiration for him that he appointed him ambassador to the Vatican—a mission which Alvarez could only discharge many years afterward, in 1533. The embassy left the Abyssinian court at the beginning of 1521, with a view of returning to Portugal; but a quarrel which broke out among the company, and which called for the interference of the negus, led to their remaining in Abyssinia till 1526, when Alvarez returned to Lisbon, where he was received with great distinction by John III., King Emanuel having died in 1521. The king prompted him to compile an account of his observations during his six years' stay in Abyssinia; and he accordingly prepared an itinerary in five books, which was published in Lisbon in 1540, under the title *Verdadeira Informação do Preste João das Indias*. Only a few copies were printed, and it soon became very rare. A mutilated copy was obtained by Ramusio, in whose collection will be found "The Journey in Ethiopia of Francisco Alvarez."

ALVAREZ, Juan, a Mexican general, leader of the revolution which in 1855 drove Santa Anna from power, born about 1790, died in 1870. He was of Indian blood, and always exercised an

extraordinary influence over the people of southern Mexico. Being governor of Guerrero in 1853, he had little difficulty in rousing his mountaineers to insurrection. The outbreak took place at Acapulco, at the beginning of the following year. In the decree promulgated by Alvarez, in March, 1854, which became noted as the plan of Ayutla, Santa Anna's deposition was officially announced, and republican institutions were proposed to the people. After Santa Anna's downfall, Gen. Carrera was intrusted for six months with the charge of the government, which, however, he relinquished in September in favor of Alvarez, whose nomination as president of Mexico was ratified by the assembly of Cuernavaca, which for that purpose he had convoked himself on Oct. 4, 1855. On Nov. 15 he made his entry into Mexico, escorted by a body guard of Indians. His abolition of the privileges of the clergy and the army met with such opposition that he tendered his resignation, substituting in his place his former minister Comonfort, Dec. 11; and after procuring \$200,000 from the national exchequer, and what arms and munitions he could get, he returned to southern Mexico.

ALVINZKY, Joseph, baron, an Austrian field marshal, born in Transylvania, Feb. 1, 1735, died in Buda, Sept. 25, 1810. He distinguished himself during the seven years' war at Torgau, at the capture of Schweidnitz, and in the engagement at Töplitz. During the peace he introduced many reforms in the tactics of the Austrian troops. In 1789 he took part, under Field Marshal Loudon, in the campaign against the Turks, and, although he did not succeed in reducing Belgrade, the emperor Joseph II. conferred upon him the dignity of lieutenant field marshal. Subsequently he was sent to Liège to quell an insurrection. He was not successful, but the confidence in his ability as a tactician remained the same, and in 1796, after the defeats of Beaulieu and Wurmser, he was put at the head of the Austrian army against Bonaparte. He obtained some small advantages over the French at the Scalda, at Bassano, and at Vienza, but he lost the two great battles of Arcole (Nov. 17, 1796) and Rivoli (Jan. 14, 1797), and was recalled, and even accused of treachery. The emperor Francis, who had been one of his military pupils, did not notice these imputations, and appointed him in 1798 superior commander of Hungary, where he reorganized the army, and 10 years later made him field marshal.

ALXINGER, Johann Baptist von, a German poet, born in Vienna, Jan. 24, 1755, died May 1, 1797. Though he was a lawyer, and held the title of court advocate, he availed himself of his legal station only to arrange disputes or plead for the poor. His principal productions are two chivalresque epics in Wieland's style, *Doolin von Mainz* and *Bliomberis*. His works were published in Vienna in 1812 in 10 vols.

ALZEY, a town in the grand duchy of Hesse, province of Rhenish Hesse, situated on the

Selz, 18 m. S. by W. of Mentz; pop. in 1867, 5,358. The chief industries are tanning and the manufacture of tobacco. It was founded in the time of the Romans, and had for some time in the middle ages its own lords, ruins of whose castle are still extant.

AMADEUS, a name very common in the ruling family of Savoy, and first borne by the eldest son of Count Humbert, in the beginning of the 11th century. The most noteworthy rulers of this name are: **I. Amadens V.**, count of Savoy, the son of Thomas II., born in 1249, succeeded his uncle Philip in 1285, and died at Avignon in 1323. He obtained the surname of Great. He largely increased his dominions by marriage, purchase, and donations. Among his exploits is mentioned a repulse of the Turks from Rhodes, then in the possession of the knights of St. John, a triumph which was believed to have led to the adoption of the "cross of Savoy," and the device F. E. R. T., or F E R T, generally explained by *Fortitudo ejus Rhodum tenuit*; but both the exploit and the explanation are now considered unauthentic. His daughter was married to Andronicus III., emperor of Constantinople. In order to induce Pope John XXII. to preach a crusade in favor of his son-in-law, he undertook a journey to Avignon, where he died. **II. Amadens VIII.**, count of Savoy, and for some time pope or anti-pope, succeeded his father Amadens VII. in 1391. He purchased the country of Genevois for 45,000 florins, and thus the house of Savoy became so powerful that the emperor Sigismund in 1416 erected Savoy into a duchy. John Paleologus, duke of Montferrat, agreed to hold the marquisate of Montferrat as a fief of the house of Savoy. By marriage and donation Amadens made yet further acquisitions. In 1434, however, he abandoned his duchy to his son and retired to the monastery of Ripaille, where he lived so luxuriously that *faire Ripaille* became a saying in the French language, signifying to make good cheer. He had never received holy orders, but was elected pope and crowned at Basel by the cardinal of Arles, under the title of Felix V. The papal dignity was contested by Eugenius IV., who was supported by France, England, Italy, Spain, and Hungary. Eugenius died, and the cardinals at Rome elected Thomas de Sarzana (Nicholas V.). Amadens resigned the papal crown in his favor in 1449, stipulating, however, that he should be perpetual apostolical legate in his late temporal dominions, that he should continue to wear the pontifical dress except in a few particulars, that he need not go to Rome to attend any general council, and that the pope should rise to receive him, and permit him to kiss his cheek instead of his foot.

AMADEUS I. (*Amadeo Ferdinando Maria*), king of Spain, duke of Aosta, second son of King Victor Emanuel of Italy, born May 30, 1845. He early held the rank of lieutenant general in the Italian army and that of rear admiral in the navy, and showed much interest

in naval affairs. He married, May 30, 1867, the wealthy Italian princess Maria del Pozzo della Cisterna, whose mother was a countess de Merode. His nomination as king of Spain, proposed by Gen. Prim, was sanctioned by Victor Emanuel, subject to the approval of the European powers, which was given in October, 1870, and to the ratification by a majority of the cortes, which took place on Nov. 16. He reached Madrid Jan. 2, 1871, Gen. Prim having been assassinated four days previously. He was himself beset by assassins (July, 1872), by Carlist risings, and by other dangers and administrative difficulties. Becoming discouraged, he abdicated the throne for himself and his heirs, Feb. 11, 1873, and returned to Italy, the cortes immediately proclaiming and organizing a republic.

AMADIS OF GAUL, the mythical hero of one of the early romances of chivalry, written by Vasco de Lobeira, a gentleman of the Portuguese court, who died in 1493. The Portuguese original is lost, and the earliest known version is the Spanish one of Montalvo, made between 1492 and 1504. It has been translated into various languages, and extended to five times its original length, and was the most popular as it is the best of all the fictions of its class. Amadis, the pattern of a perfect knight, is supposed to have flourished soon after the beginning of the Christian era, and to have gone through a variety of adventures in England, France, Germany, Turkey, and more or less imaginary countries. He is the son of an imaginary king of Gaul (perhaps Wales), and crowns his adventures by marrying Oriana, daughter of Lisuarte, king of England.

AMADOR, an E. county of California, bordering on the Sierra Nevada, bounded S. E. by the Amador river, a tributary of the Sacramento, and drained by the branches of the San Joaquin; pop. in 1870, 9,582, of whom 1,627 were Chinese. Gold, copper, marble, and quartz abound. The productions in 1870 were 16,678 bushels of wheat, 51,815 of barley, 36,760 of corn, 73,010 lbs. of wool, and 54,165 gallons of wine. There were 36 quartz mills for the production of gold, 9 saw mills, and 2 newspapers. Capital, Jackson.

AMALARIC, the son of Alaric II., and last Visigothic king of Spain, born in 501, died in 531. He was not yet six years old at his father's death, and his bastard brother would have supplanted him had not his grandfather Theodoric, king of the Ostrogoths, seized the throne and preserved it for his grandson until he reached manhood. He married Clotilda, daughter of Clovis, king of the Franks, in 527, and having treated her with great cruelty to induce her to embrace Arianism, her brother Childebert marched against him, and defeated him in battle. He was killed in the flight.

AMALASONTIA, or *Amalasintha*, daughter of Theodoric the Great, king of the Ostrogoths, born in 498, died in 535. Her husband Eutharic having died, her intellect and learning decided Theodoric to make her regent of Italy

during the minority of her son Athalaric, to whom he bequeathed that kingdom. Assuming power in 526, and availing herself of the aid of Cassiodorus, she showed great administrative talent; but her efforts to educate her son were thwarted by the Gothic nobles and by his own intractable disposition, and his debaucheries destroyed him in his youth. She still endeavored to retain power, but through the influence of Justinian was imprisoned and strangled by her cousin Theodatus, whom she had married and made co-regent.

AMALEKITES, a Bedouin tribe, who, according to Arabian traditions, lived in very early times near the Persian gulf, but were gradually driven westward by the Assyrians. When they were first known by the Israelites, they inhabited the peninsula of Sinai and its neighborhood to the north, thus controlling the routes across the isthmus of Suez. They are mentioned as defeated by the four kings, and again as harassing the march of the Israelites out of Egypt. They were afterward defeated at Rephidim, but in turn vanquished the Israelites near Hormah, where they had the Canaanites as allies. They are mentioned several times after this, but no longer as powerful; and they seem to have been almost exterminated by Saul and David.

AMALFI, a city and seaport of S. Italy, in Principato Citra, on the gulf of Salerno, 24 m. S. E. of Naples; pop. about 5,000, and with several

industries. The macaroni of Amalfi is famous, and is exported to all parts of the world.—Amalfi is believed to have been founded in the 4th century, but is not mentioned in history till the 6th. It early became an independent republic, governed by doges, and the principal centre of eastern trade, with a population of 50,000, the dependent territory comprising 500,000. It originated a new maritime code (*Tabula Amalphitana*), introduced into Europe an improved knowledge of the mariner's compass, and preserved the earliest known MS. of the Pandects. The inhabitants also acquired distinction in the crusades as the founders of the hospital of St. John of Jerusalem, from which the knights of Malta derived their name. In 1075 Robert Guiscard was called to the aid of the republic against the duke of Salerno, and afterward annexed it to his dukedom of Apulia; but it maintained a partial independence till 1181, when it capitulated to King Roger of Sicily, retaining the right of municipal self-government. Its decline in commercial importance was hastened by wars with the Pisans, by the encroachments of the sea upon its harbor from the 12th century, and the destruction of its quays and public works by a great storm in 1343. In later times the titles of duke and prince of Amalfi were held by various families.

AMALGAM (Gr. *ἀμα*, together, and *ζαμίν*, to marry; or according to some, *μάλαγμα*, to emollient, from *μάλασσειν*, to soften), an alloy

of two or more metals, one of which must be mercury. This metal has a remarkable power of dissolving most of the other metals and forming combinations that may be applied directly to various uses; and, moreover, as the mercury is easily expelled from them by heat, these combinations are used as a means of bringing other metals into a condition of convenient application to many purposes. Thus, gilding is sometimes effected by washing other metals with a solution of gold in mercury. The mercury is driven off by heat, and the gold remains coating the surface. A process is pat-

Amalfi.

independent villages about 7,000. It is encircled by mountains and precipices, at the mouth of a gorge, from which a little torrent dashes into the gulf, furnishing power for numerous mills and manufactories. It has been an archbishop's see since 987, and besides the ancient cathedral, in the Romanesque style, there are several fine churches and a Capuchin convent. The coasting trade, fisheries, and manufactures of paper, soap, and macaroni are the principal

industries in England for covering iron with zinc, which is based on this principle. A considerable degree of cold is produced in forming some amalgams. Thus, in mixing at a temperature of 65° F. 118 parts of tin and 201 of lead, both in filings, 284 of bismuth in fine powder, and 1,616 of mercury, the temperature falls to 18°. Many of the amalgams are definite compounds, from which the mercury in excess may be squeezed out; but sometimes the liquid that thus escapes

is found to be itself an amalgam, containing a smaller proportion of the harder metals, seeming to indicate two definite compounds of different proportions. This is observed with the amalgam of mercury with silver, and also with tin. In tinning mirrors, the glass plates are laid upon smooth stone tables covered with the amalgam. The solid portions adhere in a thin film to the glass; and this is a compound of atomic proportions. The liquid squeezed out by the weight placed upon the glass proves also to be an amalgam containing but a small proportion of tin.—Amalgams are prepared by putting the harder metals, reduced to small size, in mercury, and dissolving them with or without heat, as may be required. When the metals are not easily dissolved, they may be rubbed together or triturated in a mortar, or melted, and the mercury heated and poured into the fused metal. This is the process for preparing an amalgam of 4 parts mercury, 2 zinc, and 1 part tin, for the electrical machine. The zinc is first melted, the tin added, and then the hot mercury stirred in. It is to be shaken till cold, then triturated and sifted in a fine sieve. An amalgam of mercury with iron is prepared by rubbing together in a mortar clean iron filings and zinc amalgam, and adding a solution of perchloride of iron. By rubbing and heating this mixture a bright amalgam of iron and mercury is produced. Some amalgams take a crystalline form, thus indicating combination in definite proportions; and there is also a native amalgam of this character of mercury with silver. This is found in dodecahedral crystals, consisting of 1 atom of silver and 2 of mercury=36 per cent. of the one and 64 of the other. One part of gold heated with 6 parts of mercury crystallizes on cooling in four-sided prisms. Tin amalgam made of 3 parts of mercury and 1 of tin forms cubic crystals. Amalgams freed from their excess of mercury are, when freshly made, dry pasty substances, which soon become hard like stone. This property makes some of them convenient for filling cavities of teeth, but the injury the mercury may effect upon the system renders their use highly objectionable.

AMALGAMATION, the process of extracting gold and silver from the gangues in which they occur in nature by combining them with mercury. The ores are crushed and then washed through different machines in which mercury is placed. This seizes upon the little particles of the metals that come in contact with it, and brings them together into one mass, from which the earthy matters are all washed away. Any greasy substance present almost wholly prevents this effect, the grease adhering in a film upon the surface of the mercury, and thus rendering impracticable the close contact necessary for their union. The amalgam is from time to time taken out of the washing machines, squeezed through cloth or dressed deerskin, the liquid portion replaced, and the solid distilled in an apparatus suitable for saving the mer-

cury, which is then ready for use upon another lot of ore. The silver residue from distillation needs refining to render it perfectly pure. There are two processes for separating silver from its ores by amalgamation—the European process in barrels, and the American in heaps. The ore is treated in the European process by pulverizing the ore and roasting it with an admixture of common salt; by this means all the silver, which was originally a sulphide, is converted into the chloride. The roasted ore is then placed in barrels which can be revolved upon a vertical axis, and is thoroughly loosened and stirred up with water. Iron in the form of nails or scrap is then added, which takes the chlorine from the silver and yields the latter in the metallic state. Mercury is then added in larger quantity than is sufficient to amalgamate all the silver. After the barrel has revolved for an hour or more the mercury will have taken up the silver, and is then drawn off. This mercury is filtered and distilled as above described. The American process of amalgamation in heaps has the advantage of simplicity, and although not so perfect in its extraction of silver, it does not require fuel and expensive apparatus. The ore is first broken up to the size of a pea by means of rude stamps, and then ground to fine powder in round cylindrical tubs with bottoms of stone. Each tub has a horizontal arm revolving with its centre upon the vertical axis of the tub, and having at each end a chain attached to a stone weighing from 50 to 100 pounds. When the arm is revolved, these stones are dragged round and pulverize the ore. The ore is then placed on an amalgamating floor built of stone, and is mixed with a little salt and mercury. After some days the mercury is collected, filtered, and distilled as above described, to save the silver.

AMALIA, Anna, duchess of Saxe-Weimar, second daughter of Duke Charles of Brunswick-Wolfenbüttel, born Oct. 24, 1739, died April 10, 1807. She was married to Duke Ernest of Weimar in 1756. After her husband's death in 1758 she took the reins of government, and held them so well that Saxe-Weimar was able speedily to recover from the effects of the seven years' war, and escaped the famine of 1773. In 1775 she resigned the administration to her son, and devoted herself to the cultivation of literature. For 30 years she lived in the society of Wieland, Goethe, Herder, Schiller, and other men of eminence.

AMALIE, Marie Friederike, queen of Greece, born Dec. 21, 1818. She is a daughter of the late grand duke Paul, and half sister of the reigning grand duke Nicholas of Oldenburg, and was married to King Otho of Greece Nov. 22, 1836. She imparted a high tone to the court circles of Athens, and was much respected in Greece on account of her firmness, her benevolence, and her varied accomplishments. In 1836 she acted as regent during the foreign occupation of Athens. A Greek student made an attempt to shoot her in 1861. On Oct. 24,

1862, after the deposition of her husband, she went with him to Bavaria, and since his death (July 26, 1867) has resided at Bamberg. Her sister married in 1855 Maximilian de Washington, a Bavarian baron, a descendant of the English Washington family, resident in Styria.

AMALIE, *Marie Friederike Auguste*, duchess, a German dramatist, eldest sister of King John of Saxony, born in Dresden, Aug. 10, 1794, died in the palace of Pillnitz, Sept. 18, 1870. She wrote two dramas under the name of Amalie Heiter (Dresden, 1829-'30). Among her subsequent productions, which are noted for a love of humanity and virtue, her comedies *Der Onkel* and *Die Fürstenbraut* became very popular. The latter was performed in Paris under the title *Une femme charmante* (1840). Others of her plays were also adapted to the French stage. A complete edition of her dramatic works was published in Dresden, for the benefit of the women's association, under the title of *Originalbeiträge zur deutschen Schaubühne* (6 vols., 1837-'42). A 3d edition of the 1st volume appeared in 1858, and a French version of it (*Comédies*) at Paris in 1841. Six of her dramas were translated into English by Jameson (London, 1846), and six others anonymously (1848). She composed operas and sacred music.

AMALS, or *Amali*, the name of the royal family of the Goths. Of this family were all the sovereigns of this nation until the division into Ostrogoths and Visigoths. After that event the Ostrogothic kings were Amals until the extinction of the male line in Theodoric the Great. According to the legendary chronology recorded by Jornandes, the Gothic bishop and chronicler Amal, or Amala, who gave the name to the family, was the fourth descendant of Gapt, the first Gothic king. Amal is supposed to have signified spotted.

AMALTHEA, in Greek mythology, the nurse of the infant Zeus. She is commonly supposed to have been a goat, who, with her two young ones, was translated to the skies, where all three were metamorphosed into stars by the father of the gods. Zeus, according to one of the various myths on the subject, broke off one of the horns of the goat Amalthea, and presented it to the daughters of Melisseus, king of Crete. This horn was endowed with such miraculous power that whenever the possessor wished, it would instantly become filled with whatever might be desired.

AMANUS, the ancient name of a mountain range, a branch of Mount Taurus, extending in a N. E. direction from the gulf of Issus toward the Euphrates, and separating Cilicia from Syria, which it bounds on the north.

AMAR, *J. P. André*, a French revolutionist, born in Grenoble about 1750, died in Paris in 1816. Elected in 1792 to the convention for the department of Isère, he voted for the execution of Louis XVI. within 24 hours, and for the rejection of the appeal to the people. Being sent as a commissary to his own department, he showed himself a merciless persecu-

tor of his neighbors, systematically denounced the Girondists on every occasion, and contributed his part to the fall of the Dantonists, then called *modérés*, and the Hebertists, stigmatized as anarchists. He appeared to favor Robespierre's system, but materially contributed to his defeat before the convention. When in 1795 Collot d'Herbois, Billaud-Varennes, and Barrère were condemned to be transported, he presented himself as their advocate. The consequence of this act was his confinement in the fortress of Ham. He regained his liberty by the decree of amnesty rendered by the convention on its final adjournment. By order of the directory, he was subsequently arrested as an accomplice in the conspiracy of Drouet and Babouf, but released for want of legal testimony. However, he was exiled from Paris during Napoleon's reign, and spent the rest of his life in obscurity.

AMARANTH (*amarantus*; Gr. ἀμαράνθος, unfading, because the flowers retain their bright colors when dead), a genus of plants of the family of *amarantaceæ*. This genus is rich in species, most of which grow within the tropics (about 60 in Asia, 105 in America, 10 in Africa), some without the tropics (about 20 in Asia, 25 in America, 28 in New Holland, several in Africa, 5 in Europe), either in groups or singly, in dry stony situations or among thickets, few in salt marshes. The most ornamental exotic species, cultivated in Europe and in the United States, all annuals, are: *A. caudatus* (love-lies-bleeding), native of India, from 2 to 3 feet high;

Amarantus caudatus (Love-Lies-Bleeding).

leaves oval, oblong, reddish; flowers crimson, in long hanging clusters; a gigantic variety is 9 feet high. *A. sanguineus*, of India; stem and leaves blood-red; leaves oval, often emarginate; flowers red, small, axillary, with inter-nodal clusters. *A. speciosus*, of Nepal; pyramidal, 6 feet high; flowers purplish crimson along the branches. *A. tricolor*, of China;

branchy, 3 feet high; leaves yellow, red, and green; flowers green, lateral. *A. hypochondriacus* (prince's feather), with erect flower spikes and purplish foliage, is a native of Virginia. These hardy species can be sown in the open border, while the less hardy require a gentle hot-bed, whence they may be potted off singly, in rich soil, and well watered. The above-named species blossom from June to October. Many of the species, having mucilaginous leaves, are used as pot herbs, with lemon juice. *A. viridis* is emollient, good for cataplasms. The seeds of *A. frumentaceus* and *anardhana* are eaten in India. *A. obtusifolius* is diuretic. Some others are variously employed in South America.

AMARAPURA, or **Ummerapura**, a city of the Burman empire, 6 m. N. E. of Ava, near the left bank of the Irrawaddy. It was founded in 1783, and made the capital of the country, but in 1819 the seat of government was transferred again to Ava. In March, 1810, the whole city, then containing over 170,000 inhabitants, was burned to the ground. In 1827 the population was not over 30,000. Many of the public buildings present a magnificent spectacle, having their roofs richly gilt within and without. One of its temples, a vast edifice adorned with sculptures, contains a colossal bronze statue of Gautama. A whole street was formerly occupied by goldsmiths. Dr. Adolf Bastian, who visited Amarapura in 1861-'2, describes it as entirely decayed, only a suburb inhabited by Chinese exhibiting any activity.

AMASIA, **Amasieh**, or **Amasyah**, a city of Asia Minor, in the pashalic of Sivas, on the Yeshil-Irmak, 50 m. S. S. W. of Samsun on the Black sea; pop. about 25,000. It is situated in a deep valley enclosed by precipitous rocks, upon one of which, on the left bank of the river, are the remains of an ancient acropolis and two Hellenic towers. Four bridges, one probably of Roman construction, cross the river within the limits of the city. The houses are of stone, but mean and small; the bazaars are poor; and the principal buildings are in ruins. There is an active trade in raw silks, wine, madder, grain, and cotton. The early history of the town is unknown. It was the metropolis of Pontus under the Roman domination of Asia Minor. Strabo the geographer was born here, and gives a minute description of the place. The tombs of the kings, of which he speaks, are still to be seen, scooped out of the face of the rock upon which the citadel stands.

AMASIS, or **Amosis** (Eg. *Ahames* or *Ahmes*, the new moon, or engendered by the moon), the name of two Egyptian kings. **I.** The first Pharaoh of the 18th dynasty. He reigned from 1525 to 1499 B. C. He led the insurrection against the Hyksos in Lower Egypt, besieged and captured their great stronghold, Avaris, pursued them into Canaan, captured there a number of towns, and thus began that series of Egyptian wars in western Asia, in which his successors carried their arms even beyond the

Euphrates. **II.** The last ruler but one of the 26th dynasty, reigned from 569 to 526 B. C. He erected monuments in various parts of Egypt, and particularly adorned Saïs. He was a good sovereign, and is mentioned especially by Herodotus as having had friendly intercourse with Solon, and with the celebrated Polycrates of Samos. He encouraged Greeks to settle in Egypt, and maintained good relations with Cyrene and other Hellenic states. Under his son Psammenitus, who reigned only six months, Egypt was conquered by Cambyses.

AMATI, a family of Cremona, celebrated for the perfection attained by many of its members in the construction of violins and instruments of that class. **I. Andrea**, born in Cremona between 1500 and 1520, died about 1577. He is said to have served an apprenticeship as a violin maker at Brescia, and he established a shop of his own at Cremona while still a young man. The instruments used in the chamber concerts of his time, such for instance as the lutes, theorbos, guitars, and mandolins, were all soft-toned, and sweetness rather than power of tone was sought in their construction. Following this taste, his violins are remarkable for their exquisite softness of tone and the beauty of their workmanship. They are of small and medium patterns, the arch elevated; the wood of the bottom runs with the grain, the sounding-boards are moderately thick, and the varnish is of a clear brown. Very few of his instruments now exist. Charles IX. possessed a collection of 24 violins, viols, and basses made to his order by Andrea Amati. They were very elaborately ornamented, having the arms of France and various other devices painted in colors on the back.

II. Nicolò, a younger brother of the preceding, known for the excellence of his violoncellos. He is believed to have outlived Andrea, though the exact dates of his birth and death are uncertain. **III. Antonio**, son of Andrea, born at Cremona about 1550, died in 1635. He was his father's pupil, and succeeded him in business.

For a time he was associated with his brother Geronimo, and the instruments bearing their joint names are much esteemed. Antonio adopted the models of his father, but made a much greater number of small than of large instruments. His violins produce delicate, sweet, and pure tones, but they have little power. The first and second strings are the best, the third a little dull, and the fourth slightly dry in tone. His violins are all of exquisite finish; the arch is high in the centre, and the fir of which the sounding-boards are made is of a fine and delicate grain. **IV. Geronimo** (date of birth and death unknown), youngest son of Andrea, was a pupil of his father. His violins were generally of a larger pattern than those of his father and brother, and inferior to them. No violins bearing his mark subsequent to 1638 are known to exist. **V. Nicolò**, son of Geronimo, born Sept. 3, 1596, died Aug. 12, 1684. He was the most celebrated of the family, and

the greater part of the instruments known as Amatis are from his hands. He not only made great changes in the models and proportions adopted by his family, but gave to his details a higher finish and to his curves a greater perfection, while he discovered a mellower and more beautiful varnish. The relation of the swells and the thicknesses of his instruments is better planned than in those of his father or his uncle. Thence it is that, while preserving their distinguishing sweetness of tone, they attain more power and brilliancy. Some violins at which this maker would seem to have worked with unusual care are masterpieces of art. One of two dated 1688 was at Milan in the collection of Count Cozio de Salabue. In perfection of finish, purity and mellowness of tone, this instrument was considered a marvel. The great violinist Alard also possessed one of the finest instruments that ever came from the hand of this great maker. The weakest point in his violins is the second string, which, owing, it is believed, to the too sudden decrease in the thickness of the belly toward the sides, is thin, the notes Si and Do being particularly liable to this objection. As is the case with the instruments of all the other makers of this family, the tones of those made by Nicolò are slender, but in an especial degree sweet, round, and silvery.

AMATITLAN, a town of Guatemala, Central America, about 18 m. S. of the city of Guatemala, in lat. $14^{\circ} 30' N.$, lon. $90^{\circ} 17' W.$; pop. about 15,000. It lies in a volcanic region, near and somewhat below a mountain lake of the same name. It is a principal seat of the cochineal cultivation. The houses are of one story and of mud, roughly moulded. Hot springs abound in the neighborhood. The waters of the lake have a high temperature, and are supposed to possess medicinal qualities.

AMATIS LUSITANUS (that is, the Portuguese), whose proper name was JOAO RODRIGUEZ DE CASTEL BRANCO, a Jewish physician, born in Portugal in 1511, after the expulsion of all unconverted Jews from the country, died in 1568. He was ostensibly brought up as a Christian, studied at Salamanca, travelled in France, the Netherlands, and Italy, and dissected 12 human corpses in Ferrara, which was a great feat for a time when religious and popular prejudices ran so strong against the practical prosecution of anatomical science. Having settled in Ancona, he was persecuted as a Jew, and obliged to leave the town after the accession of Paul IV. in 1555. He fled from city to city to save himself from the inquisition. At last he obtained safe refuge at Salonica in Macedonia, where he passed the remainder of his days.

AMAUROSIS (Gr., from *ἀμαυρός*, dark), partial or complete loss of sight, dependent on a change in the nerve structure of the eye. The term was formerly used to denote any loss of sight the cause of which could not be appreciated by the naked eye; but the invention of the ophthalmoscope has been the means of restricting it to those cases in which the optic

nerve or its expansion, the retina, has undergone atrophy, or its component parts are so pressed upon that they are no longer capable of performing their functions. The tissue which holds together the fibres of the optic nerve being in close connection with that covering the bone in its vicinity, and with the membranes of the brain, an inflammation of these latter may by extension induce the disease. A hæmorrhage (apoplexy), or a tumor near or in the nerve, may by pressure cause this condition; or even a plugging of the artery which should supply the nerve with blood; or, finally, certain diseases of the brain or spinal cord, or of the nerve itself. The disease is usually progressive. If the cause be mechanical from pressure, of recent origin, and removable by treatment before change in the nerve structure has proceeded too far, the vision may be restored or its further loss prevented. Such cases are exceptional.

AMAURY, or **Amalie**, the name of two kings of Jerusalem. **I.** Count of Joppa, born in 1135, died July 11, 1173. He was crowned king of Jerusalem in 1162, on the death of his brother Baldwin III. He was a vain, ambitious, and imprudent prince, and passed the eight years of his reign in making war on the natural ally of the Franks, the sultan of Egypt, and his only sure support against the inroads of the Seljuk Turks. Having invaded Egypt with some success, he was soon forced to the defensive by Saladin, who continued his conquests under Baldwin IV., the son and successor of Amaury.

II. Of Lusignan, king of Cyprus, was called to the tottering throne of Jerusalem when near its downfall. His nominal reign there lasted from 1194 to 1205. He called upon the western nations to aid him against the Saracens, but the crusaders preferred stopping at Constantinople, and partitioning the Byzantine empire, to the more dangerous service against the Moslems. He left Cyprus to his son Hugo de Lusignan.

AMAURY OF CHARTRES. See **ALMARIC OF BÈNE**.

AMAXICHI, or **Amakuki**, a seaport town of Greece, capital of the nomarchy of Leucas, at the N. E. extremity of Santa Maura, Ionian Islands, separated by a narrow channel from Acarnania; lat. $38^{\circ} 50' 15'' N.$, lon. $20^{\circ} 43' E.$; pop. about 5,500. From the liability to earthquakes, the houses are chiefly of wood and of one story. It is rendered unhealthy in summer by numerous salt marshes. The harbor has an extensive mole, but is only available for small craft. The town is defended on the N. by the strong castle of Santa Maura. It is the see of a Greek archbishop.

AMAZIAH, king of Judah 838-809 B. C. See **HEBREWS**.

AMAZON, or **Amazons** (Port. *Rio das Amazonas*), the largest river on the globe, flowing easterly from the Andes to the Atlantic, and draining about a third of South America, or an area variously estimated from 1,500,000 to 2,500,000 sq. m. The Apurimac, an affluent

of the Ucayali, is by some considered as its source; but it properly rises in Lake Lauricocha near the mines of Cerro Pasco. The head waters, under the name of Tunguragua or Upper Marañon, flow northerly 500 m. in a series of rapids between the Peruvian Cordilleras, and on reaching the boundary of Ecuador run E. N. E., maintaining this course to their exit under the equator. But the Amazon is a vast river system, rather than one river. More than 350 branches and lesser tributaries unite in the grand trunk of this giant stream. From lat. 3° N. to 19° S., a distance, measured by the windings of the mountain chain, of 2,000 m., there is not a stream that descends the eastern slope of the Andes that does not contribute its waters to swell this mighty flood. Besides the Tunguragua, we find on the S. side the Huallaga, rising within a few miles of its source, and having nearly the same course and length; it is navigable by steamers to Yurimaguas and by canoes to Tingo Maria. About 200 m. below its mouth enters the magnificent Ucayali. This tributary rises near Cuzco, and has a length of about 1,200 m., with an average width for 250 m. above its mouth of half a mile, and a current of 3 m. an hour. A small steamer has ascended 773 m. from Nauta. Several large but little known streams succeed, as the Javari, Jutahi, Tefé, and Purús, the last of which has been ascended 1,800 m. But the largest contributor to the Amazon is the Madeira. At its junction it is 2 m. wide and 66 feet deep. Its extreme length is probably 2,000 m., and it is navigable 480 m. Of its affluents, the Beni rises near Lake Titicaca, and the Mamoré is separated only 15 m. from the source of the Pileomayo, the largest affluent of the Paraguay. The Tapajós, 1,000 m. long, rises within 20 m. of the head waters of the Paraguay, and is navigable 160 m. above Santarem. East of the Tapajós are the Xingú and Tocantins, navigable about 150 m., the latter of which, however, is an affluent of the Pará, and not of the Amazon proper. From the north, the great river receives the Negro, 1,200 m. long. This tributary is of commercial importance, not only because of the rich region through which it flows, but also because it is connected with the Orinoco by the natural canal Cassiquiare. Nearly parallel to the Negro are the Japurá and Putumayo, each 1,000 m. long; and further W. flow the Napo and Pastaza, rising in the Quítonian Andes, the former navigable 500 m., the other a torrent. The total length of the Amazon from its source to Pará, following the curves, is 2,750 m. If we consider the Ucayali as the head, it will measure 3,000. Lient. Hernndon estimated its length from the source of the Huallaga at 3,944 m. Though not the longest, the Amazon is the most voluminous river on the globe. The water passing Obidos every second amounts to 500,000 cubic feet, and its freshening influence is perceptible 500 m. from the coast. Some idea of its magnitude may be

gained from the fact that 900 m. from its mouth it receives a tributary 2,000 m. long. The usual current is 3 m. an hour. The depth varies from 42 feet in the upper part to 312 at its mouth; at Tabatinga, where it crosses the Brazilian frontier, it is 66 feet. It is deep at the very edge, not having those sloping shores which characterize most streams. At Nauta, 2,300 m. from the sea, it is $\frac{3}{4}$ m. wide; at the entrance of the Madeira it is 3 m.; below Santarem it is 10 m.; and if we include the Pará, its mouth is 180 m. wide. The Pará river, however, is distinct, and is joined to the Amazon by very narrow channels.—Like other tropical rivers, the Amazon is subject to periodical inundations. The banks, usually high, are overflowed, and vast tracts are flooded. The rise above the lowest level is between 7 and 8 fathoms. At Ega the rise begins about the close of February. The tide of the ocean is perceptible at Obidos, 450 m. up. The bore, or *pororoca*, as it is termed by the natives, is a phenomenon worthy of remark. It was well described by La Condamine, more than 100 years ago, in these terms: "During three days before the new and full moons, the period of the highest tides, the sea, instead of occupying six hours to reach its flood, swells to its highest limit in one or two minutes. The noise of this terrible flood is heard five or six miles, and increases as it approaches. Presently you see a liquid promontory, 12 or 15 feet high, followed by another, and another, and sometimes by a fourth. These watery mountains spread across the whole channel, and advance with a prodigious rapidity, rending and crushing everything in their way. Immense trees are instantly uprooted by it, and sometimes whole tracts of land are swept away." It is difficult for vessels to withstand such a tide, and hence those accustomed to the navigation of the river avail themselves of *esperas*, or resting places, where their vessels may be sheltered from its violence. Another characteristic feature is the system of back channels joining the tributaries, and the *igarapés* or canoe paths through the forest. One may go from Santarem 1,000 m. up the Amazon without ever entering it. The water of the upper Amazon and of the Pastaza, Huallaga, Tapajós, Xingú, and Tocantins is blue or olive-green; that of the lower Amazon and of the Madeira, Purús, Jutahi, Javari, Ucayali, Napo, Putumayo, and Japurá is yellowish; of the Negro and Tefé, black. The temperature of the water will average about 80°. The river is full of islands and sand bars, and the axis of the channel is constantly changing. A vast amount of sediment is carried into the sea, but there is no delta proper, the Marajó and other islands in the great estuary having a rocky base.—The immense valley of the Amazon is walled in by the Andes and the highlands of Guiana and Matto Grosso. No other region of equal area has such a remarkably uniform character, and its geological formation is of deep interest. Scarcely any-

thing is visible but variegated clays and a reddish sandstone. Prof. Agassiz has considered it a cretaceous basin filled with glacial drift; but Prof. Orton in 1867 discovered a highly fossiliferous deposit in the clay formation, containing extinct shells, showing it to be of pliocene or miocene date. The region traversed by the Amazon and its affluents is covered with vast forests, and possesses a soil of extraordinary fertility. "It," says Humboldt, "the name of primeval forest can be given to any forest on the face of the earth, none perhaps can so strictly claim it as those that fill the connected basin of the Orinoco and the Amazon." "From the grassy steppes of Venezuela to the treeless pampas of Buenos Ayres," says a later traveller just referred to, "expands a sea of verdure, in which we may draw a circle of 1,100 m. in diameter which shall include an evergreen, unbroken forest. There is a most bewildering diversity of grand and beautiful trees—a wild, unconquered race of vegetable giants, draped, festooned, corded, matted, and ribboned with climbing and creeping plants, woody and succulent, in endless variety. The exuberance of nature displayed in these million square acres of tangled, impenetrable forest offers a bar to civilization nearly as great as its sterility in the African deserts." Palms, leguminous trees, and giant grasses are the predominant forms. The most valuable for commerce are the caoutchouc tree and Brazil-nut tree, and more than 100 varieties of beautiful woods eminent for their hardness, tints, and texture.—Animal life is not so conspicuous in the forest as in the river. The latter is crowded with strange fishes (of which the largest is the *pirarucá*, 8 ft. long), alligators, turtles, anacondas, porpoises, and manatees. Mammals, birds, and reptiles are scattered through the forest in great variety, but few appear in any one place. The common forms are monkeys, jaguars, tapers, capybaras, peccaries, sloths, deer, armadillos, toucans, and macaws. The shores are likewise thinly inhabited; the most important tribes are the Mundurucús, Ticunas, and Yaguas. The largest towns are Pará, Santarem, Manáos, and Iquitos.—The Amazon presents an unparalleled extent of water communication. It starts within 70 m. of the Pacific, and with its tributaries touches Guiana and Paraguay. The Amazon was opened to the world in 1867, and regular lines of steamers ascend to Yurimaguas on the Huallaga. The most important exports are rubber, cacao, nuts, copaiba, cotton, hides, piaçaba (palm fibre), sarsaparilla, farina, tonka beans, annatto, and tobacco. The Amazon navigation company (Brazilian), established in 1854, had in 1872 a capital of \$2,200,000, and 9 steamers, 5 of which ply exclusively in the Amazon waters: 2 between Pará and Loreto in Peru, distance 2,100 m.; 1 on the Peruvian branch of the river, 288 m.; 1 from Pará to Obidos, 400 m.; 1 from Santarem to Faro; total distance, round trips, 10,491 m. Total receipts in

1869 for passengers and freight, \$207,452 08. Imports, \$402,580 40; exports, \$364,614 19.—Yañez Pinzon discovered the mouth of the Amazon in 1500; but the river was first navigated by Orellana, Pizarro's officer, who in 1541 descended from the Napo to the Atlantic. In 1637 Texeira ascended by the Napo to Quito, and Father Acuña, who accompanied him, published the first description. The name Amazona is derived either from the Indian word *amassona*, boat-destroyer, or from Orellana's story of his fight with a nation of female warriors; which fable probably grew out of the fact that the men part the hair in the middle and wear long tunics. The old names of the river, Orellana and Paraná-tinga, are obsolete. Alto Amazonas, or Upper Amazon, is applied to all above the Negro. To the middle Amazon, between Tabatinga and Manáos, the name Solimoens is sometimes given. The part above Tabatinga, or the Peruvian portion, is called Maraón, which includes the Tunguragua.

AMAZONAS. I. The northernmost province of Brazil, bounded N. by Guiana and Venezuela, N. W. by Colombia, W. by Ecuador and Peru, S. by Peru, Bolivia, and the Brazilian province of Matto Grosso, and E. by the province of Pará. Its limits have not been precisely defined; pop. about 80,000. The surface is covered by virgin forests, and but little known. In this province, at and near the town of Manáos, the river system of South America unites. The principal streams are the Amazon (which above Manáos is called the Solimoens), Negro, Putumayo, and Madeira. **II.** A N. department of Peru, bounded N. by Ecuador; area, about 18,000 sq. m.; pop. 44,000, besides about 60,000 Indians of nomadic tribes. It is traversed by the Andes. The soil, which is watered by the Maraón and several of its affluents, is extremely fertile, and produces wheat, corn, rice, all sorts of fruits and vegetables, sugar cane, tobacco, cacao, coffee, cotton, indigo, quinine, and sarsaparilla in abundance. Its virgin forests are rich in mahogany, cedar, and other valuable timber. The chief industries are the manufacture of sugar, rum, cottons, and woollens, and the salting of fish. Capital, Chachapoyas.

AMAZONIA, a title given by the geographers of the 17th and 18th centuries to an unexplored tract in the central portion of the Amazon basin, supposed to be inhabited by a tribe of warlike women, who governed themselves, and would tolerate no males in their community.

AMAZONS (Gr. *a* privative and *μαστός*, breast), a race of warlike women, whose original seat is said to have been in the country adjoining the Caucasus. They were believed to be governed by a queen, and to propagate the species by cohabiting once every year with the Gargareans, a nation of men whose territory was separated from that of the Amazons by a chain of mountains. Their male children were either sent to the Gargareans or put to death. Their female children were deprived of the

right breast, and trained by their Amazon mothers to war, hunting, riding, and agriculture. The favorite deities of the Amazons were Mars and the Taurian Diana. The Amazons were fabled to have made extensive conquests in the early ages, in Asia, Africa, and Europe, and to have founded several cities in Asia Minor and the islands adjoining it, such as Ephesus, Smyrna, Cyme, and Paphos. It is a question with ancient writers whether these extraordinary women ever existed.

AMBASSADOR, or **Embassador**, a term generally applied to the highest class of diplomatic representatives in foreign countries. In an official sense it designates only those who are accredited by one potentate to another, and who represent the sovereign himself, while ministers plenipotentiary and envoys extraordinary, although accredited to the crown, represent only the state, and not the person of its chief. The queen of England, for instance, sends ambassadors to the most influential sovereigns, but only a minister plenipotentiary to the United States. The American minister plenipotentiary and envoy extraordinary (the title ambassador being not often used, although it is mentioned in the act of congress of 1856 relating to the diplomatic service) is consequently outranked at European courts by the ambassadors of the pettiest sovereign princes. The legates and nuncios of the pope are entitled to the same social and diplomatic privileges as ambassadors. An ambassador may at all times demand a personal interview with the sovereign as a matter of right, while the minister plenipotentiary can only claim an audience as a favor. Ambassadors extraordinary are those sent on special missions, and occupy a still more exalted position than those called ordinary, who permanently reside at a court. Ambassadors in the principal non-Christian countries enjoy extra-territorial rights, based upon the fiction that they carry along with them the whole territory of their sovereign, so that the country represented is deemed to be present in China, Japan, Turkey, &c., as well as its sovereign himself, in the person of the ambassador. The extra-territorial rights of ambassadors and other official representatives of Christian powers in the East are guaranteed by treaties, and are predicated upon their jurisdiction over more or less extensive communities of their countrymen and over other persons under their protection.

AMBER, a hard, light, nearly transparent resinous substance, found in loose pieces in alluvial deposits, or scattered along the coast after severe storms. It was regarded by the ancient Greeks and Romans with superstition, and in mythology was spoken of as the tear drops shed by the sisters of Phaëthon, and petrified as they fell into the sea. The electrical phenomena first exhibited by this substance (which the Greeks called *ἤλεκτρον*) added to its mystery. It was even believed by some of the philosophers to be possessed of a soul. The

Arabs, noticing the same phenomena, gave it the name in their language of *karabé*, catch-chaff. The Romans called it *succinum*, and the ancient Germans *glissum*. The ancient trade in amber is described in Sir George Cornwall Lewis's "Historical Survey of the Astronomy of the Ancients" (London, 1862). Amber is now generally understood to be a fossilized vegetable gum. The trees from which it exuded stood in forests of past epochs, and are now found forming strata of bituminous wood beneath beds of sand and clay. The wood is more or less impregnated with the amber; and this is also met with depending from the trunks in the form of stalactites, and again in rounded pieces mixed with pyrites and coarse sand under the layer of trees. Such a bed is worked as a mine for the amber near the coast of Prussia. The fossil stratum is from 40 to 50 feet thick, and is followed to the depth of 100 feet below the surface. In other countries it is found in beds of brown coal and of lignite; and it is probable that the pieces of it picked up on the seashores have been washed out from the extension of these repositories beneath the waters of the sea.—On the Prussian coast of the Baltic, between Königsberg and Memel, amber is more abundant than in any other known locality. From this source the great demand for this material in the Mohammedan countries is principally supplied. The trade was first appropriated by the grand masters of the Teutonic order, who often paid by it the whole expense of their court. After it became a royal monopoly it was guarded by most stringent laws; "strand riders" patrolled the coast, and a peasant concealing or attempting to sell a piece of amber he had found was hanged on one of a range of gallows kept standing *in terrorem*. Since the beginning of the present century the government monopoly has been farmed out to private contractors. Prosecution for theft may still be instituted against persons who retain pieces of amber they have picked up, and any one passing certain limits of the beach may be punished as a trespasser. The amber is washed ashore in considerable quantities near the village of Stürmen. Not only is it found in the sands on the shore, but also in the interior at a greater or less depth beneath the surface of the earth. At present the chief amber diggings in the north of Prussia are on the N. and W. coasts of Samland, N. E. of Königsberg. These are worked by an open excavation into the mountain near its base, in which the amber-bearing bed is laid bare, sometimes presenting a thickness of 2½ feet. Exhausted in one place, a new excavation exposes it in another. The fishing and picking of amber from the sea furnishes employment to great numbers of people. This is generally undertaken after a storm, when the swell of the waves is moderate. The workmen wade into the sea, and catch in nets the seaweed which is borne in by the waves. This is spread on the shore, where the women and

children collect from it pieces of amber of various sizes, which is delivered by them to the superintendent. This mode of procuring amber is always less laborious and often more productive than digging. In winter, when the sea by the shore is covered with ice, the ice crust is broken through and the seaweed and amber are picked up through the opening. The fishers frequently go out in small boats when the supply near the shore fails, and in this way a large quantity of amber is found, though it is less valuable than that gained by digging. Bag nets are used in fishing for amber, and long spears in drawing large pieces out of the surf. The production in 1869 by digging, fishing, and spearing on the coast of Samland was 700 quintals. The dredging machines at Schwarzort on the Cur Flats obtained 795, and the diving at Brüsterort, between the Cur and the Fresh Flats, 215; making a total of 1,710 quintals, valued at 700,000 thalers. The diving apparatus used was placed in the Paris exhibition of 1867 by Capt. Rouquayrol Venayrouse, its inventor.—Amber is used almost wholly for small ornaments, as necklaces, and especially for the mouthpieces of pipes. A varnish is also prepared from it, as well as an oil used in medicine, and succinic acid, a useful reagent in chemical investigations, so called from *succinum*, the Latin word for amber. The largest piece of amber known is one weighing 13½ lbs., in the mineralogical museum at Berlin. The value of the specimens is not at all proportionate to their sizes. A piece of a pound weight might sell for \$50, while one of 13 lbs. weight would readily bring \$5,000.—Amber is of a yellow brownish or whitish brown color, transparent or translucent, and resembles rosin. Its specific gravity is 1.08. It is nearly as hard as calcareous spar, and is susceptible of a fine polish. When rubbed it becomes negatively electrical. Heated to 448° F., it melts, and then takes fire, burning with a yellow flame, and evolving much black smoke and an agreeable odor. The analyses that have been made of it give proportions of carbon varying from 70 to 80 per cent., hydrogen from 7 to 11, and oxygen from 7 to 8. Its principal ingredient is a resin insoluble in alcohol, which forms 80 to 90 per cent. of the whole. With this is found a resin soluble with difficulty in alcohol, and a trace of an odorous volatile oil. The products of its distillation are inflammable gases, water holding succinic and acetic acids and empyreumatic oil in solution (the spirits of amber of old pharmacy), sublimed succinic acid (salt of amber), and an empyreumatic oil (oil of amber). The residue is 12 to 13 per cent. of charcoal.—Pieces of amber are often met with containing the remains of insects that have become entangled in the substance when it was of thinner consistency. Their legs and wings are sometimes seen detached from the bodies, as if the insects had struggled hard to disengage themselves from the sticky mass. These insects resemble more those of tropical

climates than such as are now known in the regions where amber is found. According to Tausche (1860), there have been found in amber 5 species of crustacea, 33 of myriapoda, and 205 of arachnida; of insects, 24 species of aptera, 60 of hemiptera, 8 of orthoptera, 87 of neuroptera, and, according to Loew (1864), 850 of diptera, the latter chiefly of the proboscidean division. Leaves of fern plants, and occasionally some mineral substances, are also met with in amber. Loew believes the amber fauna to be a fragment of a larger fauna, and chiefly found in sluggish waters and ponds and in rotting wood.—It is not known when the property possessed by amber of attracting light substances when rubbed was first noticed. It is spoken of by Thales of Miletus, Theophrastus, and Pliny. Electricity is excited to such a degree in the processes of working amber into the forms in which it is sold, that the workmen are affected with nervous tremors, and are obliged to change frequently the pieces they handle, that the excited electricity may be dispersed.—Amber has recently been discovered in various parts of Courland. It is also found in several other parts of Europe, Asia, and in E. Africa. False amber is sent from India to China, and is sold for nearly the same price as the genuine article. Amber is found at various places in the United States, occurring in the greensand formation and in the clays which succeed it, associated with lignite. The principal localities are at Amboy, N. J., at Gay Head on Martha's Vineyard, and at Cape Sable in Maryland.—The commerce in amber is divided by its tints, the bright yellow transparent variety being esteemed in Europe, while the clouded whitish yellow is preferred throughout Asia, far more than the other is elsewhere, not alone for jewelry, but for general decoration of personal utensils. It forms the favorite mouthpiece of the oriental tobacco pipe, from its presumed power of resisting infection, the more necessary where it is discourteous to wipe a pipe passed from one person to another, as much the symbol of unity as the calumet of our Indians. Singular to say, Americans follow the orientals in preferring the whitish mottled variety. Gum copal has been substituted for amber, which it resembles, but it can be distinguished by its enclosing modern insects, while amber holds only extinct varieties; also by copal burning steadily, while amber has marked scintillation.

AMBERG, a town of Bavaria, formerly capital of the Upper Palatinate, on both sides of the Vils, 35 m. E. of Nuremberg; pop. in 1871, 11,688. It is a neat and well built town, with a great number of churches, schools, colleges, hospitals, and other public buildings, a royal palace, an arsenal manufacturing from 10,000 to 20,000 stand of arms yearly, a salt magazine, manufactures of glass, iron, cotton, tobacco, stoneware, and hats, and important iron mines, yielding about 8,000 tons yearly. In the neighborhood of Amberg the rear guard of the

French under Jourdan was defeated by the archduke Charles, Aug. 24, 1796.

AMBERGER, Christoph, a famous German painter of Amberg (whence the name), born at Nuremberg about 1490, died at Augsburg in 1568. His best productions are his portraits, in the style of Holbein, whom he imitated. His historical paintings are small, and hard and sharp in style.

AMBERGRIS, a perfume, generally used in its alcoholic solution. It is a morbid secretion of the liver of the spermaceti whale, and is principally found floating upon the seas of warm climates intermixed with remains of the food of whales; it is also met with in the intestines of the whale. When of good quality it is of a bright gray color, streaked with black and yellow, so soft that it may be flattened in the fingers, and exhaling an agreeable odor if rubbed or heated. Its fracture presents a fine grain, its cut surface a waxy appearance. It is somewhat lighter than water, fuses at 140° to 150° F., and at a higher temperature gives out a white smoke, which condenses into a crystalline fatty matter. It contains about 85 per cent. of a peculiar fatty, fragrant substance called ambreine, which is extracted by boiling in alcohol, and separating the crystals that form in the cooled solution.—Persons engaged in whale fishing look for ambergris in the intestines of the spermaceti whale, and are most successful in finding it in those that appear torpid, sick, and lean; whence it would seem that the substance is a product of disease. It is in the lower part only of the intestinal canal, mixed with the feces, that the substance is found. The lumps of it are from 3 inches to a foot in diameter, and from 1 lb. to 20 or 30 lbs. in weight. The largest piece known was bought by the Dutch East India company of the king of Tidore; it weighed 182 lbs. A piece weighing 130 lbs. was found inside of a whale near the Windward Islands, and was sold for £500 sterling. Genuine ambergris emits a fragrant smell when a hot needle is thrust into it. It also melts like fat to a uniform consistence. The counterfeit does not present these peculiarities.

AMBIORIX, one of the most famous of the Gallic chiefs who fought against Julius Cæsar toward the middle of the first century B. C. Conjointly with the superannuated Cativolens, he was ruling over the Eburones, on the lower Meuse, when the country was invaded by Cæsar, who strove to corrupt him, but only made him dissemble while waiting his opportunity. During Cæsar's second excursion to England, Ambiorix organized an extensive conspiracy, which broke out after the Roman legions had gone into winter quarters. Having by stratagem induced one garrison to leave their fort, he massacred them to a man. He was about to attack another camp when Cæsar marched to its relief, and easily dispersed the assailants. Cativolens took poison, but Ambiorix, with a few friends, made his escape into the forests.

AMBLETEUSE, a small decayed seaport of France, on the English channel, in the department of Pas-de-Calais, 5 m. N. of Boulogne. Here James II. landed on his flight from England in 1689. Napoleon, while meditating an invasion of England in 1804, attempted unsuccessfully to improve the harbor of Ambleteuse for his flat-bottomed boats. In the vicinity is the famous granite column erected by Napoleon to the grand army in 1805.

AMBOISE, a town of France, in the department of Indre-et-Loire, on the left bank of the Loire, 14 m. E. of Tours; pop. in 1866, 4,188. The town was rendered conspicuous at the opening of the French religious wars, in the 16th century, by the plot framed there against the Guises, known as the conspiracy of Amboise. The ancient castle, which has been the residence of several kings of France, stands on a rocky precipice, and is almost inaccessible. It is of Roman origin, was rebuilt in the 4th century, and lastly renovated by Louis Philippe. Abd-el-Kader was confined here during the greater part of his captivity. The town has manufactures of firearms and files.

AMBOISE, George d', a French statesman and cardinal, born at Chaumont-sur-Loire in 1460, died in Lyons, May 25, 1510. As a younger son he was destined for the church, and was titular bishop of Montauban at the age of 14, and later archbishop of Rouen. During the lifetime of Charles VIII. he belonged to the party of the duke of Orleans; and when the latter ascended the French throne as Louis XII. in 1498, Amboise at once became prime minister. He prevailed on the court of Rome to annul the marriage of Louis XII. with Jeanne de France, and received from Alexander VI. the cardinal's hat. He accompanied Louis XII. into Italy, and arranged the affairs of Milan after its conquest by the French troops. At the death of Alexander VI. he aspired to be pope, but the Italian cardinals passed him over, and elected first Pius III. and afterward Julius II., in spite of his lively antagonism, which threatened a schism. He left a large fortune.

AMBOYNA, or **Amboina** (Malay, *Ambon*, dews), an island in the Malay archipelago, the most important though not the largest of the Moluccas or Spice Islands, between lat. 3° 26' and 3° 48' S., and lon. 127° 57' and 128° 27' E.; length 85 m., average breadth 10 m.; area, about 300 sq. m.; pop. 32,000. A deep, narrow bay, called the bay of Binnen, 14 m. long, almost bisects it. The two halves are composed of high hills rising abruptly from the sea, and covered with tall, coarse grass, groves of the cocoa palm near the shore, and thick forests in the valleys and near some of the summits. The island is of primitive formation. It is subject to earthquakes every year, after which fevers commonly prevail, but in other respects the climate is very healthy. There are few animals except the wild hog, deer, and horse. Birds are abundant and of many species, and the coasts have long been famous for multitudes

of beautiful shells. The commonest fruits are the coconut, mango, banana, nutmeg, and pineapple, the last having been introduced from the West Indies. Excellent indigo is raised, and the cajuput tree furnishes a medicinal oil. Indian corn has been introduced, and now forms with sago the staple food of the Malay natives. Cacao is extensively cultivated, and is rapidly supplanting the clove, of which, however, there are still valuable gardens on the hillsides. The production of cloves was once a valuable monopoly of the Dutch government. At the time of the Spanish occupation (1581-1607) it was immeasurably greater than it is now. The spice is cultivated on this island and the three little islands of Haraku, Saparua, and Nusalaut, lying immediately east of it, and the total yield of the four is about 785,000 lbs., of which Amboyna supplies about one third. The population of Amboyna consists principally of Malays, most of whom profess Mohammedanism. Savage aborigines called Horaforas still exist in the forest, and there are Chinese, Europeans, and half-breeds at the capital. The native villages are governed by rajahs appointed by the Dutch resident. The island was discovered by the Portuguese in 1515, was acquired by Spain in 1581, when Philip II. conquered Portugal, captured by the Dutch in 1607, and by the English in 1615, and retaken by the Dutch in 1622, when a horrible massacre of the English settlers took place, for which Cromwell afterward compelled the Netherlands to make compensation. In 1796 the island was once more taken by the British. They restored it at the peace of Amiens in 1802, seized it a third time in 1810, and it reverted finally to Holland in 1814.—**Amboyna**, the capital of the island and of the Dutch government of the same name, which includes Amboyna, Ceram, Amblauw, and Buro, is situated on the S. E. shore of the bay of Binnen, in lat. 3° 40' S., lon. 128° 15' E., 8 or 9 m. from the sea; pop. 14,000, of whom 9,000 are natives, 400 Arabs, 300 Chinese, and 700 nominally Europeans, though nine tenths of them are half-caste Dutch. The city has a pleasant aspect from the sea, occupying a level area, with broad, straight, and well shaded streets. It has a hospital, a public garden, and two Christian churches. The government is administered by a Dutch assistant resident, subordinate to whom are a rajah for the Malay population and a "captain China" for the Chinese. There is a fort called Nieuw Victoria. Good anchorage is found in the harbor, and the port is annually visited by about 200 vessels and praus of all kinds. There is a monthly mail steamer to Batavia. The imports, valued at \$200,000 to \$300,000 annually, consist chiefly of cotton goods and rice, and the exports of cloves, cocoa, cajuput oil, nutmegs, mace, and various kinds of wood. The port has been free since 1854, but the trade is much less prosperous than it was during the last English occupation.

AMBACIA (now *Arta*), a town of ancient Greece, on the left bank of the Arachthos, N. of the Ambracian gulf (now gulf of Arta), which separated Epirus from Acarnania, though originally the town was included in the latter division. It was colonized by the Corinthians about 660 B. C., and early acquired importance. About the time of Alexander the Great it became subject to the kings of Epirus, of whom Pyrrhus made it his capital, and adorned it with public buildings. Having joined the Ætolian league, it was taken by the Roman conquerors in 189 and stripped of its works of art. At a later period its inhabitants were transported to the new city of Nicopolis, at the western extremity of the gulf, opposite Actium, founded by Augustus Cæsar to commemorate his victory over Mark Antony off the last named place. (See **ARTA**.)

AMBRIZ, one of the divisions of the Portuguese colony of Angola in W. Africa; area, 89,800 sq. m.; pop. reported at about 2,100,000, but much less according to the official statements of the Portuguese government. The town of Ambriz, or Oporto do Ambriz, is at the mouth of the Loge or Ambriz river, in lat. 7° 52' S. It was formerly the port of the small negro kingdom of Ambriz, the capital of which is Quibanza. The Portuguese annexed the town in 1855; in 1865 it contained 16 factories or trading stations, two of which were American.

AMBROSES, a nation of Gaul, who lived near the Alps between Switzerland and Provence. They joined the Cimbric and Teutonic in their invasion of the Roman territories, and were routed, together with the latter, and almost annihilated, by Marius, in the battle of Aquæ Sextiæ (Aix), in 102 B. C. Their women, after a futile attack upon the Roman soldiers who were following in pursuit of the flying foe, offered to yield on the condition that their chastity should be respected. This proposition being rejected, they first slew all their children and then themselves.

AMBROSE, Saint, one of the fathers of the Latin church, born at Treves, in Gaul, in 340, died at Milan in 397. His father was the Roman governor of Gaul, but his mother was a Christian. He was trained to the law, and intrusted at an early age with the government of a province. His probity and wisdom in this public administration seemed to justify his removal to the place of bishop, although at the time of his election he had not even been baptized. The various objections and stratagems by which he tried to escape the honor thus pressed upon him were all disregarded; and at the age of 34 he was consecrated bishop of Milan, and continued to hold this office until his death, a period of more than 22 years. His predecessor, Auxentius, was an Arian. The sympathies of Ambrose, however, were with the supporters of the Nicene creed. He would not tolerate the Arian worship, and though he protected an Arian priest from the

violence of the mob, he resisted the dictation of the empress Justina, who wished that an Arian bishop should be appointed for the city. He rebuked Valentinian, defied Maximus, and compelled Theodosius to a humiliating penance and submission. When all the officers of the court were silent upon the massacre which in a fit of anger Theodosius had ordered at Thessalonica, Ambrose declared to the emperor that his crime was beyond absolution without a special act of penance, and that the mass could not fitly be celebrated in such a presence. His boldness prevailed, and the emperor humbly obeyed his orders, and continued ever after to be his firmest friend. His contest with Symmachus is scarcely less remarkable. At the instigation of this learned man, then prefect of Rome, the senate took the occasion of a famine in 383 to ask that the pagan worship might be revived. Ambrose was prompt to throw against the scheme all the force of his authority and eloquence. He was by no means the equal of his adversary in graces of rhetoric and fulness of scholarship, but his earnestness, and perhaps in some degree his threatenings, won the cause.—The writings of Ambrose fill two folio volumes in the editions of Erasmus (Basel, 1527) and the Benedictines (Paris, 1686-90). His moral teaching has throughout an ascetic tone, though less austere than that of the Greek fathers. He was hostile to all amusements and all pleasures of sense, and commended the monastic life as the truest way of Christian obedience and spiritual growth. He wrote treatises on "Widows," on "Virginity," on "Penance," and on the "Duties of Ministers," which satisfied the severe taste of Jerome much better than his seven books on "Faith and the Holy Spirit," which that harsh critic pronounced to be at once weak, fantastic, and stolen from the Greeks. His panegyrics, as we read them now, hardly justify his reputation for a wonderful oratory. Of his letters only a part have come down to us. They show very faithfully the character of the man, his moderation, courage, fidelity, practical wisdom, and unaffected piety. There was a dignity in his manner and bearing which made him appear at once like a ruler and a saint. Arbogastes, a Roman general, making war upon the Franks of the Rhineland, was asked by one of their chiefs whom he had conquered if he was a friend of Ambrose. From motives of policy he gave an affirmative answer. "No wonder that you have beaten us," was the reply, "since you have the favor of a man whom the sun itself would obey if he should command it to stand still." The most valuable legacies of Ambrose to the church were the hymns which he wrote and the improvements which he made in the method of chanting the sacred offices. The most famous of these are the morning song, *Æternæ verum Conditor*; the evening song, *Deus Creator omnium*; the Christmas chant, *Veni, Redemptor gentium*; and the short hymn to the Trinity,

which Luther translated and adopted. These hymns of Ambrose are not to be praised for the beauty of their diction or for any artistic merit. They are rude, loose, and as far from the musical flow of later Christian rhyming as from the ancient finish of classic Latin verse. But their vigor, their fervor, their striking imagery, not less than their association with the revered name of their author, give them a place in the veneration of the faithful. The body of Ambrose is kept in the ancient basilica of Milan which bears his name, and his feast day is observed by the Latin church on the 7th of December, the day of his ordination as bishop. He has also the honor of a place among the saints of the eastern church, and his name is classed on their registers with the names of Basil, Athanasius, and the two Gregories.

AMBROSIA, in Greek mythology, the food of the gods, which was brought to Zeus by pigeons, and which conferred upon the dwellers on Olympus eternal youth and immortality. It supplied the place of all terrestrial comestibles. Favorites of the gods are recorded to have had it given to them as a great favor. It was also used by the gods to anoint their body and hair; hence we read of the ambrosial locks of Zeus.

AMBROSIAN CHANT, a method of singing hymns first introduced into the western church by St. Ambrose, about 386. Although generally supposed to be the foundation of all church music, it was in fact derived through the eastern church from the Greeks, and is so little known at this day, that it is impossible to say more of its general character than that it was constructed on the ancient Greek tetrachords, and embraced the four authentic modes, the four plagal or collateral ones being added by Gregory to form what is known as the Gregorian chant. The Ambrosian chant, and indeed all kinds of church music, were at first limited strictly to the performance of the psalms and doxologies, from an apprehension among the early fathers and bishops that heretical doctrines might creep into the services by the introduction of original hymns. Ambrose, however, in imitation of the Greek fathers, subsequently wrote several hymns, including, it has been erroneously supposed, the *Te Deum*, which he caused to be habitually sung according to the new method in his church; and St. Augustine, who was baptized there, speaks with great delight of the impression which the performance of the psalms and hymns made upon him. The Ambrosian chant continued to be used in the services of the church until about the commencement of the 7th century, when it was superseded by the new method adopted by Pope Gregory.

AMBROSIAN LIBRARY, a collection founded in Milan in 1609 by Cardinal Federigo Borromeo, archbishop of that city, and named in honor of St. Ambrose. It is especially rich in MSS., for the collection of which learned men were sent into all parts of Europe, and into Asia. A very large number of palimpsests belong to this

library; some of them are exceedingly rare and valuable, among which may be mentioned Cicero's *De Republica*, fragments of his orations, and the letters of Marcus Aurelius and Fronto. The palimpsests were mostly obtained from the monastery of Bobbio, and were discovered by the librarian, Angelo Mai, in 1814. There is a MS. of Virgil, valuable for its marginal notes by Petrarch, among which is one relative to his first meeting with Laura. The library at present contains about 90,000 printed volumes and more than 15,000 MSS., besides a large collection of statuary, antiques, medals, and pictures. Among these are Raphael's cartoon of the "School of Athens" and the studies of Leonardo da Vinci. Many of the treasures of this library were carried to France during Napoleon's campaigns in Italy, and some of them have never been returned. A printing press is connected with the library, and several professors and editors are constantly engaged in collating and translating the MSS.

AMBULANCE (Lat. *ambulare*, to walk), a temporary and movable military hospital, formed on the field of battle for the immediate succor of the sick and wounded. The word is technically applied to covered wagons on springs, and to such other vehicles as are used for moving wounded men from the field of battle to the temporary hospitals, or for carrying the sick and wounded with the moving columns or to the permanent hospitals. The ambulance is a comparatively modern invention, due mainly to the French. Military surgery was formerly but little understood, and those who were wounded on the field of battle were left to the care of those around them, without any selection of fit persons for the duties of surgery. Nor do we find any trace of a regularly organized system of military hospitals, moving with the army, until the time of Henry IV. of France. The movable ambulances at first consisted of a cumbrous depot of surgical and medical appliances, kept with the baggage at a distance. At present two kinds of ambulances are recognized: one fixed or general, the other movable and light. The larger and reserved ambulances remain with the heavy baggage at some distance from the field of battle, and may be established either in permanent buildings or in large tents or temporary structures. In the late war in France the temporary hospitals fitted up in the palace of Versailles and in the public buildings of Paris were called ambulances. The lighter and more strictly movable ambulances accompany the soldiers on the field. The system was brought to its highest state of efficiency in the United States army during the civil war. The surgeons accompanying the troops are supplied with abundant means, such as lint, plaster, and bandages, for dressing wounds, and with the necessary instruments for surgical operations. Ambulances, or small spring wagons drawn by one or two horses (to which the term is in the United States commonly confined), and con-

taining all the necessary appliances, including beds, for transporting two or more patients, follow close after the troops on the march and in approaching the field of battle. The ambulances of each division or corps d'armée are organized into a corps under the command of a subaltern of the line, styled ambulance officer. Railway cars and steamboats have been provided with beds and all other conveniences for carrying sick and wounded soldiers to the permanent and more distant hospitals. The American ambulance system, with local modifications, is now used by most civilized nations.

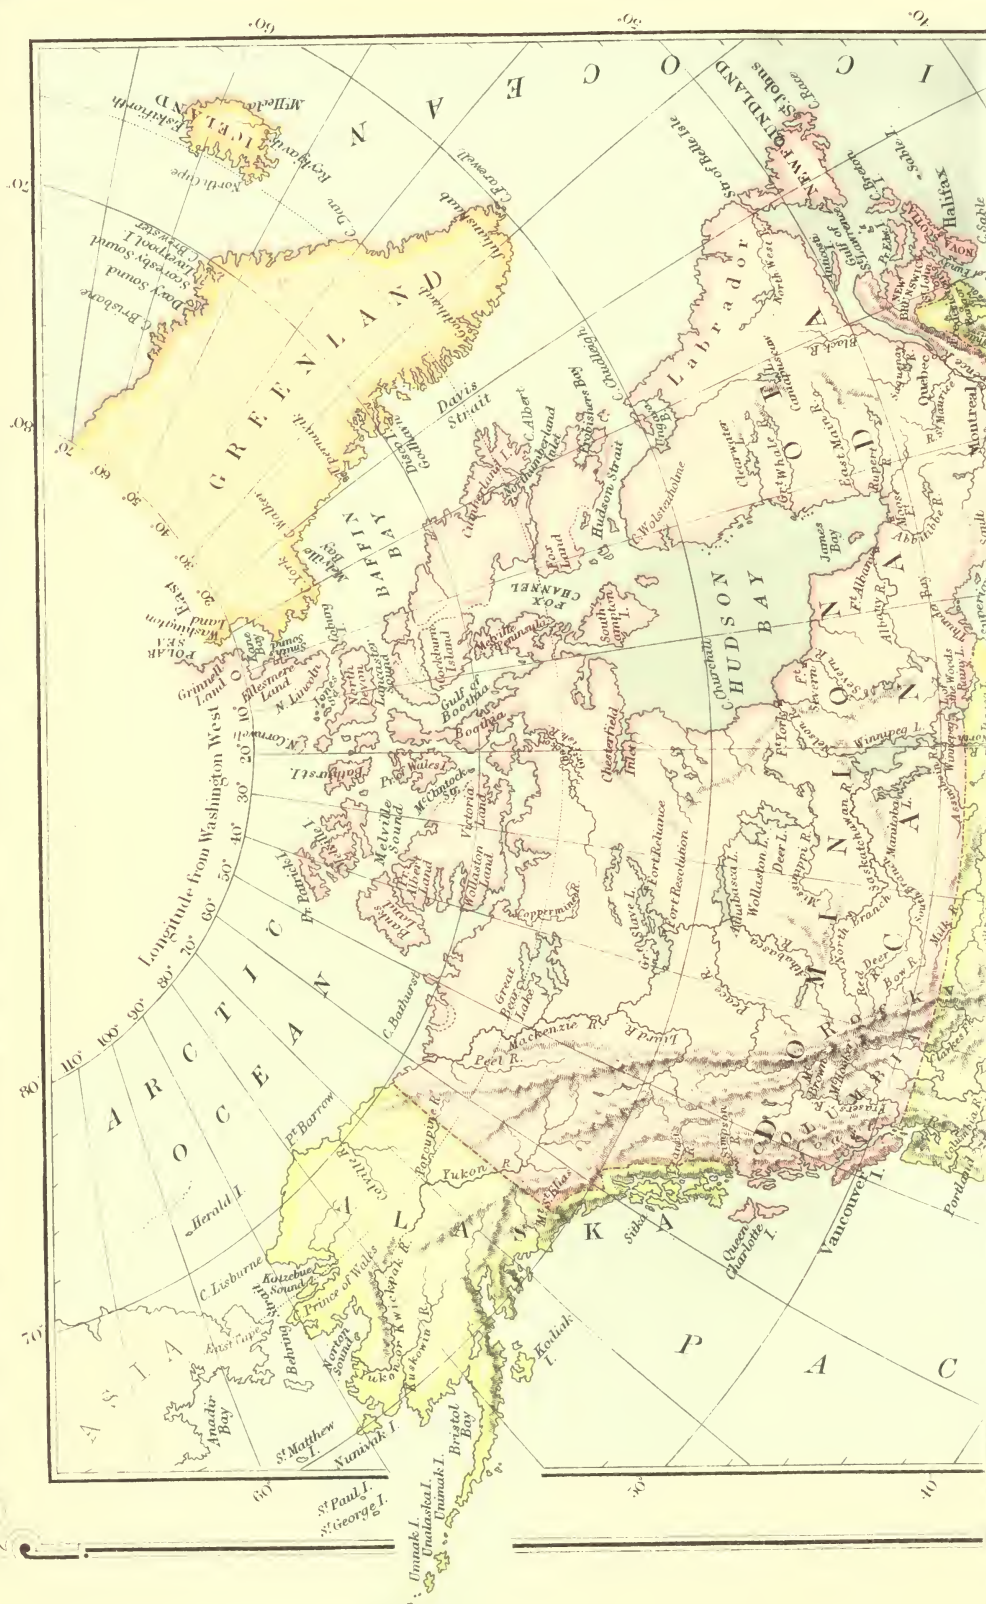

AMELIA, a S. E. county of Virginia, drained by the branches of the Appomattox river, which almost encircles it; area, 300 sq. m.; pop. in 1870, 9,878, of whom 6,823 were colored. It is intersected by the Richmond and Danville railroad. The surface is somewhat diversified. The productions in 1870 were 64,607 bushels of wheat, 70,509 of corn, 62,688 of oats, and 1,037,721 lbs. of tobacco. Capital, Amelia Court House.

AMELOT DE LA HOUSSAYE, Abraham Nicolas, a French author, born in Orleans in 1634, died in Paris, Dec. 8, 1706. After his return from Venice, whither he went in 1669 as secretary of an embassy, he devoted himself to history, politics, and philosophy. His principal work was a "History of the Government of Venice," besides which he wrote several volumes of miscellaneous memoirs, and translated four books of Tacitus, Machiavelli's "Prince," in the notes to which he spoke of his author as a great satirist, and Paolo Sarpi's "History of the Council of Trent," with very free annotations. This translation of Fra Paolo was attacked by the ultramontanists, who presented three memorials for its suppression, while it was defended and eulogized by the Gallicans. The "History of Venice," by its exposure of the secret policy of that republic, raised a great outcry there; and it is said that, through the intervention of the Venetian senate, Amelot was thrown into the Bastille.

AMELOTTE, Denis, a French writer, born in Saintes in 1606, died in Paris, Oct. 7, 1678. His life of Charles de Coudren, second general of the congregation of the Oratory, of which he was a member, contained some strictures on Duvergier de Hauranne, which brought him into collision with the Port Royalists. His influence with the chancellor Séguier prevented the publication of their translation of the New Testament, and in 1666-8 a translation of his own in 4 vols. 8vo, with annotations, was published, which, although imperfect, was superior to any of its predecessors, and is still extensively used.

AMENOPHIS, Amenoph, or Amen-hotep, a name borne by three Egyptian kings belonging to the 18th dynasty, which commenced with Amasis or Aahmes I., about 1525 B. C. I. The second Pharaoh of that dynasty, who married the widow of Aahmes, continued the conquests begun by his predecessor, after the expulsion

of the Hyksos, in southern Canaan; subdued the Shasu of the desert east of Egypt; and made an expedition toward Ethiopia, to extend the southern frontiers of his kingdom, and restore the financial prosperity of the country destroyed by the shepherd kings. He reigned 21 years (1499-1478). **II.** The son and successor, in 1414, of Thothmes III., and father of Thothmes IV., of whom little is known. His reign was short. **III.** The son of Thothmes IV., devoted himself during a reign of at least 36 years (about 1400-1364) to the improvement of his kingdom. Ancient Egypt was never so prosperous nor so extensive as under his administration. It extended into Syria as far as the western bank of the Euphrates, and south, embracing a part of Ethiopia. Monuments of the greatness of Amenophis III. exist all over Egypt, among them the two large colossi, one of which is celebrated as "the vocal Memnon."

AMERBACH, Johann, a German printer, born in Swabia, died about 1520. He was educated in Paris, and established his press at Basel in 1481, publishing the works of St. Ambrose (1492), and the first collected edition of the writings of St. Augustine (1506), from which the name of St. Augustine type was given to a variety of large letter used in the book. He proposed to publish the works of Jerome also, and to this end had his three sons thoroughly educated in Hebrew, Greek, and Latin. The edition was, some years after his death, issued by Froben. Amerbach was one of the first to substitute the Roman for Gothic and Italic letters.—His son **Boxiraz** (1495-1562), professor of civil law at Basel, was one of the most intimate friends of Erasmus and his general legate. He was distinguished as a Latin and Greek scholar and writer.

AMERICA, one of the four great recognized continental divisions of the globe. It is bounded N. by the Arctic ocean; E. by the Atlantic, which separates it from Europe and Africa; W. by the Pacific, which separates it from Asia; and S. by the Antarctic ocean. The longer axis of the American continent runs almost due north and south. Measured on its central line, lon. 70° W., its length from the arctic regions to Patagonia is about 10,500 m. From east to west it presents two shorter axes, each of something more than 3,000 m.: one from Labrador to British Columbia, nearly in lat. 51° N.; the other between Capes St. Roque in Brazil and Parina in Peru, in about lat. 5° S. The American continent is separated into two not very unequal parts by the isthmus of Darien or Panama, less than 30 m. wide at its narrowest point. All north of this isthmus (taken in its more extended sense) is known as North America; all south of it as South America; the greater part of the isthmus itself being styled Central America. Estimates of the area of America vary considerably, some authorities making it a little more than 14,000,000 sq. m., others raising it, including Greenland, to more than 17,000,000 sq. m. It may be set down at

15,000,000 sq. m., of which about 8,000,000 are in North America and 7,000,000 in South and Central America. The area is thus about four times that of Europe, nearly a third greater than that of Africa, and about six sevenths that of Asia. Geographically, America lies within the arctic, the northern and southern temperate, and the tropical zones. About one seventh is unavailable for cultivation; the remainder is not surpassed in capacity to sustain life by any equal area of the globe. The population, including that of the islands, is about 85,000,000, not far from $\frac{1}{15}$ that of the entire globe.—The geology of America is worthy of careful study. The oldest strata are a range of crystalline rocks which crop out from the St. Lawrence and the great lakes to the Arctic ocean; these consist chiefly of gneiss, granite, and trap. In North America this primary range is about 1,500 miles in length, with a breadth of 200, seldom reaching an elevation of 800 feet. It forms the western slope of the Andes and Rocky mountains. It extends over the eastern part of South America, hidden in the valley of the Amazon by alluvial deposits. In the central portion it dips under the Silurian strata, but is free from superincumbent deposits, showing that even in the Silurian age it formed dry land, and has suffered less disturbance than is manifested in most other formations. The Silurian rocks, consisting of sandstone, limestone, slate, shale, &c., are divided into several periods, and abound in fossil remains. The Silurian strata dip under the Devonian, which are in parts overlaid with conglomerate. The latter forms the basis of the carboniferous strata which occupy large portions of Pennsylvania and the valley of the Mississippi. At the close of the carboniferous period the continent, nearly as large as at present, was scarcely elevated above the ocean. The great mountain ranges are of more recent origin. They were forced through the Silurian, Devonian, and carboniferous strata, dislocating and disturbing the hitherto horizontal layers. It is where the ancient rocks have been penetrated by masses of igneous rock that the precious metals are usually found. The volcanic fires have long since been extinct in the Appalachian range; but proofs of their former existence are found in the metamorphosed Silurian and carboniferous rocks of New York and Pennsylvania, which were long supposed to be primary granite. This igneous force still manifests itself in the volcanoes of the Andes and Cordilleras. Volcanoes still active, at greater or less intervals, mark the whole of the Andean range from Chili to Alaska, the most intense action within the historical period being in Ecuador, within two or three degrees of the equator. Here is the volcano of Cotopaxi, one of the two or three in constant eruption.—The animals native to America differ in many respects from those of the other hemisphere. This is especially the case with the larger species. The elephant, hippopotamus, and rhi-

noceros of the eastern continent are in America represented by the much smaller tapir; the camel and dromedary by the llama and vicuña; the lion and tiger by the jaguar and panther. Of the carnivora the bear is the only species in America which exceeds its congeners in the other hemisphere, the grisly bear of California being the largest of its species. The American bison exceeds in size any others of its kindred, and the largest members of the deer family are natives of America. Among the carnivora native to America are the grisly, white, black, and brown bears; wolves and foxes of various species; the puma, jaguar, lynx, and wild cat. Of the marsupialia, there is every variety of the opossum; of the rodentia, the beaver, hare, marmot, mouse, porcupine, and squirrel; of the ruminantia, many varieties of deer, among which are the moose or elk and reindeer, the bison, musk ox, sheep, goat, and antelope. The quadrupeds (apes) differ specifically from their congeners on the eastern continent; all of them have long tails, and many prehensile tails, which is a peculiarity of American species. The horse and ox are introductions from Europe. Among the birds there are some species, as the wild turkey, toucan, and humming bird, peculiar to America. There are eagles, and others of the same family, vultures (among them the great condor of the Andes), ravens, crows, and an immense variety of the smaller birds, few of them being identical with those bearing the same names in Europe and Asia. Serpents are numerous. Among these are the great boa and the rattlesnake, peculiar to America. Alligators swarm in the tropical and subtropical rivers; turtles in the tropical seas. The lakes and streams are prolific in fish, among which the salmon have a wide range. The cod fisheries of the banks of Newfoundland are unequalled in productiveness. Some regions are infested with insects, especially mosquitoes. There is a native wild bee, but the common hive bee was introduced from Europe.—The vegetable productions of America are very numerous. The pine, oak, and maple are characteristic of the temperate regions; palms, of many species, of the tropical. In some parts of southern America the trees are so knotted together by twining plants as to render the forests impenetrable to wild animals, except through narrow paths which they have constructed. Maize is the only important cereal native to the new world. Nearly all the fruits of the old world have been introduced into America, where they flourish in their appropriate latitudes. The vine is a native, and within a few years its cultivation has received great attention.—We proceed to give more detailed statements under the general divisions of the continent. I. NORTH AMERICA extends from the arctic region southward to near lat. 15° N. It is bounded N. by the Arctic ocean, E. by the Atlantic and gulf of Mexico, S. by the gulf and Central America, and W. by the Pacific. Its entire eastern coast line from Barrow strait to

the southern extremity of Mexico, including the shores of Hudson bay and the gulf of Mexico, is about 13,000 m.; the western coast, being less deeply indented, has a shore line of not more than 11,000 m.; or 24,000 in all. Reclus, counting in the adjacent islands, gives the shore line of North America as 29,969 m.; South America, 16,012; together about one third more than that of Asia, about three times that of Africa, and considerably more than twice that of Europe. To the maritime system of North America properly belong also the great lakes, or inland seas, which it is estimated contain a third of all the fresh water of the globe.—North America has three main systems of mountains and watersheds, which divide it into four great hydrographical basins: 1, that which empties its waters into the Pacific ocean; 2, into the Arctic; 3, into the Atlantic; 4, into the gulf of Mexico. Each of these great basins is divided into two or more parts. The Rocky mountain range, skirting the Pacific coast, is a continuation of the Andes of South America. At the isthmus of Panama it sinks low, rarely attaining the height of 1,000 ft., with depressions of less than half that altitude. From the isthmus the range rises gradually, through Mexico and the United States, up to lat. 60° N., where it begins to sink into the Arctic basin. This mountain range bears different names in different parts of its course. Through Mexico, where it forms a broad table land, it is known as the Mexican Cordilleras. It is only in the United States and the British possessions that it bears the specific name of Rocky mountains. The Spaniards designate the whole as the Sierra Madre (Mother Range). Its general elevation is from 5,000 to 9,000 ft., with many summits much loftier. Among these are Orizaba and Popocatepetl in Mexico, which exceed 17,000 ft., and several in the United States and British America of from 12,000 to 18,000 ft. Mt. St. Elias, about lat. 60° N., reaches or surpasses the height of 17,850 ft. This range follows the shore line at various distances, the greatest deviation being about lat 40° N., where the Pacific slope of the Rocky mountains has a breadth of some 600 m., upon which are situated the states of California and Oregon, and the territories of New Mexico and Utah. The Rocky mountain range is not a single ridge, but rather, like the Cordilleras of South America, a parallel pair of ridges. Between the two lies the isolated basin of the Great Salt lake. As the Rocky mountains run so near to the coast of the Pacific, the rivers flowing from them, draining only a small area, are necessarily small. The Columbia and Sacramento, flowing directly into the Pacific, and the Colorado, flowing into the gulf of California, are the only ones of any considerable size. The Yukon, although flowing into Behring sea, a part of the Pacific ocean, belongs to a different hydrographical system. Skirting the Atlantic coast is the Appalachian range. Starting from the promontory of Gaspé, on the gulf of St. Law-

rence, it runs southwestward for 1,300 m. to northern Alabama, where it sinks to the level of the gulf slope. The Appalachian system consists of several parallel ridges, divided into two main lines. The eastern ridge is made up of the Green mountains of Vermont, the Highlands of New York, the South mountains of Pennsylvania, and the Blue Ridge of Virginia, North Carolina, and Georgia. The western ridge comprises the Adirondaek, Catskill, Alleghany, and Cumberland ranges. Between these two ridges lies an almost continuous valley, with a breadth of from 15 to 60 miles, designated in various parts as the valleys of the Champlain, the Hudson, the Cumberland, the great valley of Virginia, and the valley of Tennessee. The general tendency of the Appalachian ridge is to a greater elevation as it runs southward; the White mountains of New Hampshire being merely an isolated projection from the central mass of the Green mountain range. Except in a few points this range rarely reaches an elevation of 4,000 ft. Mount Mansfield, the highest summit of the Green mountains, is 4,359 ft.; Mount Marey, the highest of the Adirondaeks, 5,337; Mount Washington, the loftiest of the White mountains, 6,285, an elevation exceeded by many points near the southern extremity of the chain, the highest being Mitchell's peak, in North Carolina, 6,732 ft. The Appalachian chain is pierced at intervals by gaps which give passage for rivers, canals, and railways, linking the Atlantic slope with the valley of the Mississippi. The Appalachian ridge forms the watershed between the streams which flow into the Atlantic, with the exception of the St. Lawrence, and those which fall into the Mississippi, and thence into the gulf of Mexico. Several of these rivers are of considerable size, such as the Merrimack, Connecticut, Hudson, Delaware, Susquehanna, Potomac, and James. The Atlantic slope of North America, from the St. Lawrence to Florida, varies in width from 50 to 200 m., the mean elevation of its upper margin being from 150 to 1,000 ft. Throughout its whole extent it is without marked transverse ridges. The Rocky mountains and the Appalachians form two sides of a triangle, only the latter is broken off without reaching the point of junction. The third side of this triangle is formed by a broad low swell, without any defined crest, and rarely reaching the elevation of 1,500 ft. This swell, starting from the eastern base of the Rocky mountains in about lat. 50° N., runs eastward, separating the waters which fall into the Arctic ocean and Hudson bay from those which find their way into the gulf of Mexico. So gradual is the rise that we can define its summit only by noticing whether the general course of the streams is northward or southward. This low swell divides the continent of North America east of the Rocky mountains into two nearly equal parts, the northern half of which is almost all incapable of cultivation. A little

west of the head of Lake Superior this swell divides. One branch sweeps southeastward, the other northeastward, forming between them the basin of the lakes whose waters pass through the St. Lawrence into the Atlantic. So slight is the elevation of the southeastern watershed that a canal with no cutting of more than 100 feet would open an outlet for the waters of Lake Superior, Michigan, Huron, and Erie into the Mississippi, and thence to the gulf of Mexico, instead of into Ontario, and through the St. Lawrence into the northern Atlantic. The lake basin of North America is thus closely connected with that of the Mississippi. Between the eastern slope of the Rocky mountains and the western slope of the Appalachian range lies the basin or valley of the Mississippi. This is in some respects the most notable on the globe. Its area is about 1,250,000 sq. m., being only exceeded in extent by the valley of the Amazon. Latitude, elevation, and rainfall combine to render every part of it capable of supporting a dense population. Next to it in this respect comes the basin of the Plata in South America. The most striking physical feature of the basin of the Mississippi is its uniform plain-like character. From the mouth of the river to its sources there is nothing like a mountain. At its junction with the Missouri it is but 381 ft. above the level of the sea; at its source in Lake Itasca it is 1,680 ft., the average descent for the whole distance being less than eight inches to the mile. Its great affluent, the Missouri, from Fort Benton to the junction, falls only ten inches to the mile. The Ohio, from Pittsburgh to its mouth, falls less than five inches to the mile. The Red river falls a little more than a foot, the Arkansas not quite two feet to the mile. Except on its exterior rim, the basin drained by the Mississippi and its main branches falls less than six inches to the mile. The consequence is that there are no rapids to obstruct navigation, each river being navigable as far as the depth of water will permit. The entire navigable length of these rivers is about 40,000 m. The hydrography of the remaining regions of North America is of little consequence, the Rio Grande being the only other river of any importance upon the eastern side.—With the exception of purely tropical productions, North America has nearly every species of grain, fruit, and vegetable. It has given to the eastern continent maize, which next to rice is the cereal which enters most largely into human consumption, directly as an article of food, and indirectly as sustenance for animals.—North America is rich in nearly every valuable mineral. Iron is so widely diffused, especially within the United States, that it may be considered universal. Copper is found in many localities, the most abundant deposits being in the region of Lake Superior. Gold and silver have been found in every part of the Rocky mountain and Appalachian chains, the deposits in Mexico, California, and the adjacent

regions probably exceeding those of all the rest of the globe. Lead is found in various parts, the main locality, probably the most productive in the world, being in Illinois, Iowa, Missouri, and Wisconsin. Quicksilver has hitherto been found chiefly in Mexico and California, where the mines equal in productiveness those of Austria. Zinc has been found only within a limited area, mainly in New Jersey and Pennsylvania. Tin is the only valuable metal which does not occur in large quantities. The coal fields of North America comprise more than seven eighths of all known to exist. Those already explored exceed the entire area of Great Britain. Salt is widely diffused, the principal saline springs being in New York, Virginia, and Michigan. Petroleum, which may properly be classed among mineral substances, abounds within a comparatively limited area, the central point being in northern Pennsylvania, thence extending northward and westward.—Politically North America is divided into British America, the United States, and Mexico. British America occupies the whole northern half, with the exception of Alaska, the extreme northwestern angle, formerly Russian America, but now by purchase belonging to the United States. It is bounded N. by the Arctic ocean, E. by Davis strait and the Atlantic, S. by the United States, and W. by Alaska and the Pacific (where its shore line is very narrow, only about 350 m.). Its entire area is about 3,500,000 sq. m.; but with the exception of a border on the St. Lawrence and the lakes, and a very narrow strip on the Red river, and a portion on the Pacific, the whole of British America lies north of the line of cultivation. The population is 4,455,000, of which the larger part are of European descent. Nearly all of habitable British America is now consolidated as the Dominion of Canada.—The United States occupy the central part of North America, from the Atlantic to the Pacific. They are mainly bounded N. by British America (Alaska occupying an isolated position), S. by Mexico, E. by the Atlantic, and W. by the Pacific. The total area, including Alaska (580,107 sq. m.), is about 3,600,000 sq. m. The population by the census of 1870 is 38,558,371, of whom 33,589,377 are white, 4,880,009 colored, 63,254 Chinese, and 25,731 settled Indians.—Mexico is bounded N. by the United States, E. by the gulf of Mexico and the Caribbean sea, W. by the Pacific, and S. by Central America. It has an area of nearly 800,000 sq. m., and a population estimated in 1868 at 9,173,052, of whom more than half are set down as Indians, and only about 1,000,000 whites, the remainder being of mixed blood and negroes. II. CENTRAL AMERICA, occupying the greater part of the isthmus of Darien, comprises the states of Guatemala, San Salvador, Honduras, Nicaragua, and Costa Rica, which since 1863 have formed a loose political union, under the name of States of Central America. They contain about 175,000 sq. m.,

with a population estimated in 1865 at 2,665,000, of whom 1,500,000 are Indians, 1,000,000 of mixed blood, 130,000 whites, and 25,000 blacks. Central America lies wholly within the tropics; but many parts of it are sufficiently elevated to give a temperate climate. III. SOUTH AMERICA extends from Cape Gallinas, lat. 12° 30' N., to Cape Horn, lat. 55° 59' S., its extreme length being 4,550 m. The distinguishing physical feature is the chain of the Andes or Cordilleras, which borders the whole W. coast, at a distance of from 50 to 100 m. from the shore, gradually sinking at the southern extremity to the level of the ocean, a few summits appearing as rocky islands. From lat. 22° S. northward the range widens, spreading into a series of ridges generally parallel, the westernmost ridge, almost continuous, being the Andes proper, or Cordillera of the coast. The main line follows, or rather constitutes the isthmus of Panama, an offshoot striking northeasterly to the Caribbean sea. This last is divided into several parallel ridges, through the intervening valleys of which the Atrato and the Magdalena flow northward into the Caribbean. The general chain is nowhere broken through, and thus forms a complete separation between the waters which flow into the Pacific and those which fall into the Atlantic. On the Pacific side there is no considerable river. From the eastern base of the Andes several ranges of highlands divide the whole country into a number of shallow basins. Topographically South America is divided into seven distinct regions: 1. The shore of the Pacific, 50 to 100 m. in breadth, the extremities of which are fertile, the centre being a sandy desert. 2. The elevated table lands lying between the folds of the main Andes and the other Cordilleras; the chief of these are those of Quito and Bogotá. 3. The basin of the Orinoco, a series of llanos, or level plains thinly wooded, but covered during the wet season with late herbage, which withers in the dry season, when the heat is intense. 4. The great basin of the Amazon, covering about 2,600,000 sq. m., for the most part densely wooded and thinly peopled. 5. The basin of the Rio de la Plata, a series of plains, known as pampas, the river banks clothed with forests, and the interior covered with luxuriant grass, which supports immense herds of cattle, millions of which are annually slaughtered for their hides. The cattle here probably excel in number those of all the rest of the globe. 6. The mountainous region of E. and S. Brazil, extending from the Atlantic to the interior, where it almost imperceptibly joins with the two former regions. 7. Patagonia, occupying the whole breadth of the continent from about lat. 40° S. to Cape Horn. This region is almost wholly unexplored. The Argentine Confederation claims dominion over a great part of it; but practically it is inhabited only by savages, with scarcely a trace of even a tribal government. About three fourths of South America lie geographically within the tropics; but the

climate is greatly modified by the elevation.— With the exception of a small tract in the N. E. angle, comprising French, Dutch, and British Guiana, no part of South America is under the dominion of any foreign power. The present political divisions are eleven in number. We enumerate them in geographical order, commencing at the north: 1. Venezuela, in the north, bordering on the Atlantic and Caribbean sea; area, 425,000 sq. m.; pop. about 1,250,000. The only census ever taken was in 1847, when the population was 1,267,000, since which it has probably decreased somewhat owing to frequent revolutions. The bulk of the population are of mixed Indian and negro blood, hardly one in a hundred being put down as pure whites. 2. The United States of Colombia, formerly known as New Granada, bounded N. by the Caribbean sea and Central America, E. by Venezuela, S. by Brazil and Ecuador, and W. by the Pacific. It comprises the southern part of the isthmus of Darien, the Panama railroad running through it. Area, 500,000 sq. m.; pop. in 1864, 2,794,000, since which time partial enumerations indicate a slight increase. Most of the population is of mixed races. Those in whom European blood predominates over Indian are about 1,480,000; Indian over European, 440,000; Indian and negro, 440,000; pure Indian, 150,000; negro, 90,000. 3. The empire of Brazil, the only monarchy, stretching westward in its northern part from the Atlantic to Colombia, in its southern part to Bolivia. It includes the greater part of the basin of the Amazon. Area, 3,140,000 sq. m. The population is variously estimated at from 10,000,000 to 12,000,000. The best native authority gives it in 1867 at 11,780,000, of whom 9,880,000 were free, 1,400,000 slaves, and 500,000 uncivilized Indians. The proportion of people of mixed blood is small compared with other South American states. 4. Uruguay, bounded by Brazil, the Atlantic, and the Argentine Confederation; area, 75,000 sq. m.; pop. 300,000. 5. Paraguay, bounded by Bolivia, Brazil, and the Argentine Confederation, the only country with no seacoast; area, 70,000 sq. m.; pop. in 1857, 1,300,000, but since greatly reduced by war and famine. 6. Bolivia, extending from Brazil to the Pacific; area, 575,000 sq. m.; pop. 2,000,000. 7. The Argentine Confederation, extending from Bolivia and the Andes to the Atlantic; area, 600,000 sq. m.; pop. 1,800,000. 8. Patagonia, occupying the extreme southern end of the continent; area, 350,000 sq. m. The population is insignificant, consisting wholly of savages, destitute of any organized government. All the foregoing states are E. of the Andes. The remaining ones are on the Pacific shore, the summits of the range, and its eastern slope. 9. Ecuador, upon and just S. of the equator; area, 275,000 sq. m.; pop. about 1,300,000, of whom half are reckoned as whites, though many are of mixed blood. Its cultivated parts comprise a narrow strip on the Pacific, the ele-

vated valley of Quito, between the ridges of the Cordilleras, and the eastern slope of the latter. Within its limits are several of the loftiest peaks of the Andes. 10. Peru, S. of Ecuador, crossing the Andes, and extending down the eastern slope; area, 600,000 sq. m.; pop. 2,500,000, of whom 15 per cent. are whites and 57 per cent. Indians. 11. Chili, occupying the narrow Pacific coast S. of Bolivia and W. of the Argentine Confederation and northern Patagonia; area, within its established limits, about 150,000 sq. m.; pop. in 1868, 1,900,000. IV. ISLANDS OF AMERICA. The islands not immediately adjacent to the mainland, which may be properly considered as belonging to the American continent, are grouped as follows: 1, the Greater Antilles, including Cuba, Hayti, Jamaica, and Porto Rico; 2, the Lesser Antilles, including Barbadoes and about 30 others; 3, the Bahamas, about 500 in number, most of them uninhabited. Their total area is not far from 100,000 sq. m., with a population of over 4,000,000. With the exception of Hayti, these are subject to different European powers. To these may be added Greenland, belonging to Denmark, the population of which numbers only a few thousands.—The area and population of the American continent may be summed up in round numbers as follows:

COUNTRIES.	Area, sq. m.	Population.
NORTH AMERICA.		
British America.....	3,500,000	4,455,000
Mexico.....	800,000	9,175,000
United States.....	3,600,000	8,558,000
Totals, North America.....	7,900,000	52,188,000
CENTRAL AMERICA.		
Costa Rica.....	20,000	185,000
Guatemala.....	49,000	1,180,000
Honduras.....	47,000	350,000
Nicaragua.....	55,000	400,000
San Salvador.....	10,000	600,000
Totals, Central America.....	175,000	2,665,000
SOUTH AMERICA.		
Argentine Confederation.....	600,000	1,800,000
Bolivia.....	575,000	2,000,000
Brazil.....	3,140,000	11,780,000
Chili.....	150,000	1,900,000
Colombia.....	500,000	2,000,000
Ecuador.....	275,000	1,300,000

Paraguay.....	70,000	325,000
Patagonia.....	350,000	400,000
Peru.....	600,000	2,500,000
Uruguay.....	75,000	300,000
Venezuela.....	425,000	1,250,000
Totals, South America.....	7,240,000	26,250,000
ISLANDS.....	100,000	4,000,000
Totals, America.....	15,410,000	85,192,000

—The history of America, as authentically recorded, hardly goes back five centuries, or about 100 years before the colonization by the Europeans. For everything earlier we have only the ruins left by extinct races, and traditions in which the mythical element is predominant. It is certain that the Northmen

visited Greenland as early as the 10th century, and planted a colony there, with which they maintained an almost continuous intercourse. They also sailed for some distance down the Atlantic coast; but there is no evidence that they ever reached further south than New England, or penetrated a score of miles into the interior. But wherever Columbus and his followers went, they found the country peopled more or less densely by a race or races to whom they gave the general appellation of Indians. When and whence they came is unknown. The widely spread race which we group together as Esquimaux bear a strong resemblance to the inhabitants of Siberia on the one side and those of Lapland on the other. They may have reached America from one side by way of Iceland, or on the other by crossing Behring strait; not impossibly by both. But in either case intercourse with their European and Asiatic kindred was early interrupted. There is little likelihood that any intercourse existed between the dwellers on Baffin bay and those on Behring strait. Both live mainly on the products of the sea—salmon in the one case, and seals in the other; consequently they never move far from the shore. There is no evidence that they have ever moved southward to more hospitable regions than those which they now inhabit. The name Esquimaux is of French origin. In the regions around Baffin bay they call themselves Innuits, which means simply folks. In almost every respect they differ widely from the tribes who were found spread over the whole of what now constitutes the United States E. of the Rocky mountains. The early explorers found this whole region peopled by a race homogeneous in physical character and way of life. It is clear, however, that they had been preceded by another race of a higher type. This race, known as the mound-builders, certainly occupied the whole extent of the valley of the Mississippi, and penetrated as far north as the copper region of Lake Superior, where they have left behind them evidences that they had made no inconsiderable advances in the art of working metals. Their principal memorials are found in the earthworks which they erected. Of these many thousands have been found in the single state of Ohio. Their number and magnitude prove them to have been the work of a numerous people organized into large communities. How and when this people disappeared is beyond even plausible conjecture. Passing southward, we come to Mexico, which was found occupied by a people more advanced in many respects than we can suppose the mound-builders to have been. The ruling race at the time of the conquest were the Aztecs; but they had occupied this place for only a few generations. They were apparently immigrants to the table land of Anahuac; but it is still a disputed question whether they came from the north or the south. Their civilization was undoubtedly engrafted

upon an earlier one, to which the name of Toltec has been given. In the southern Mexican states of Yucatan and Chiapas, and in Honduras and Guatemala, are ruins of large cities which evince a still higher grade of culture. The existence of these great ruins shows that this region, where the present population is hardly ten to the square mile, was once densely peopled. In the part of South America E. of the Andes, the aboriginal population never attained to any form of civilization. That portion of South America occupying the elevated valleys between the various ranges of the Andes, within the present states of Peru, Bolivia, and Ecuador, was the seat of a civilization known as that of the Incas. The time of its origin is variously stated; some place it back three or four thousand years or more; but a more probable date is about A. D. 1000. It was at its height at the period of the Spanish conquest. Taken as a whole, the civilizations of the prehistoric races of America are generally regarded as purely indigenous, having no connection with and but slight resemblance to those of any other peoples. (See AMERICAN ANTIQUITIES.)—The historical period of America as fairly written begins with the discovery of the West Indian islands by Columbus in 1492. In the course of different voyages he sailed for some distance along the shores of the continent. In 1497 the Cabots discovered Newfoundland, and coasted as far down as Florida. The Spaniards took the lead in conquest and partial colonization. Within half a century they took possession of the islands; Cortes conquered Mexico, Balboa and others Central America, and Pizarro and Almagro overran Peru. The Spaniards were adventurers rather than colonists; their chief object was gold, and they pushed mainly into the regions where this was found. They reached New Mexico before 1537. Brazil was formally occupied by the Portuguese in 1549, fell successively under the dominion of Spain and Holland, and was finally recovered by Portugal in 1654. The French took formal possession of Canada in 1534, and laid claim to the region westward and southward, including the valley of the Mississippi. The English were much later in colonizing. Their first permanent settlement at Jamestown was made in 1607. The Dutch and Swedes also, not long after, settled at a few points. In 1770 the American continent was divided among three European nations. England, having taken the French, Dutch, and Swedish possessions, held by claim the whole of North America, except Mexico. Spain held Mexico, Central America, and the whole of South America, except Brazil, which belonged to Portugal. Somewhat later, Russia acquired an extensive territory in the extreme N. W. of the continent. In 1775 began the series of revolts which in less than half a century almost entirely expelled the European governments, except Great Britain, from the continent of America. The thirteen British colonies rose in 1775, and proclaimed

their independence in 1776, which was acknowledged in 1783. In 1807 the connection between Portugal and Brazil was virtually dissolved, the royal family abandoning Europe, and taking refuge in America. The rising in the Spanish possessions began soon after in Buenos Ayres, Venezuela, and Chili. Mexico revolted in 1810, and secured its independence in 1821. The other states followed at various intervals, Bolivia in 1824 being the last. In 1825 the surrender of the castle of San Juan de Ulloa removed the last vestige of Spanish dominion on the American continent. In 1867 Russia sold her possessions to the United States.

AMERICAN ANTIQUITIES. A large part of what are called the antiquities of America consist only of the architectural and other remains of the aboriginal tribes and nations, which were displaced or subjugated by European conquest and settlement. Such are many of the ruined temples and other edifices of Peru, Cen-

tral America, and Mexico, as well as most of the ruder monuments of New Mexico, and probably all of those still ruder earthworks and rock sculptures which are found eastward of the Alleghanies. Cartier in Canada, and Smith in Virginia, as well as the pilgrims in New England and the French in western New York, all found the Indians constructing defences, consisting of ditches, embankments, and palisades, the remains of which are still numerous, and which have been variously ascribed to Celtic, Hebrew, and Tartar origins. So too Coronado, who marched into New Mexico as early as 1540, found there in perfect condition and actual use those singular edifices of fort-like dimensions and numerous stories, which since, abandoned and ruined, under the name of *casas grandes*, have been claimed as monuments of a supposed migration of the Aztecs from some undefined northern region, or from the frozen wastes of Kamtchatka, beyond the straits of Behring. Cortes in Mexico, Grijalva and Montejo in Yucatan, Alvarado in Guatemala, and Pizarro and his captains in Peru, all found vast and imposing structures, the work of the actual inhabitants, the ruins of which are almost universally confounded with those of more ancient monuments, the earlier works of the same hands or of unknown or extinct peoples. It is certain that Cholula, Uxmal, and Chichen, Quiché and Pachacamac, were all perfect and occupied at the time of the conquest. Hence their remains, however interesting and valuable as illustrating American aboriginal art, can hardly be considered as falling within the denomination of American antiquities. Under this head, in a strict sense, we can only include such monuments as were really regarded as antiquities by the aborigines themselves, concerning the origin of which they were wholly ignorant, or only possessed a traditionary knowledge. Of this character are most of the earthworks and mounds on the terraces of the Mississippi valley, and in the forests bordering on the Mexican gulf. Such also are the ruined pyramids of Teotihuacan and the crumbling edifices of Mitla, in Mexico; the still more elaborate structures and sculptured monoliths of Palenque and Copan; and the vast enigmatical monuments of Tiahuanaco on the southern shore of Lake Titicaca in Bolivia; to say nothing of the bewildering remains of Man-siche or Grand Chimu in northern Peru.—Commencing with our own country, we find

Casa Grande, New Mexico.

Fortified Hill, Butler County, Ohio.

Fortified Hill, Butler County, Ohio.

in the Mississippi valley a succession of earthworks, manifestly defensive in character, extending from the lakes southward to the gulf. They generally crown the summits of steep hills, and consist of an embankment and exterior ditch, of varying dimensions, with approaches often artfully covered. Fort Hill, on the banks of the Little Miami river in Ohio, has a line of circumvallation nearly four miles in extent, varying in height, according to the natural strength of the point protected, from 10 to 20 feet, and embracing an area of several hundred acres. When not erected near to streams, and in cases where springs are not included within their lines, we almost always find artificial reservoirs for holding water. A large class of

Ancient Works near Chillicothe, Ohio.

these defensive works consist of a line of ditch and embankment, or of several lines one within another, carried across the necks of peninsulas or blunt headlands formed within the bends of streams. Associated with these defensive works, and often included within them, are structures connected with religious ideas and ceremonies. They consist of earthworks with their ditches, when such exist, interior and not exterior to the walls, of regular outline, squares, circles, octagons, and other geometrical figures, often combined, and sometimes of great extent; as for instance at Newark, Ohio, where they cover an area of more than two miles square, and probably comprise upward of 12 miles of embankment from 2 to 20 feet in height. (See "Monuments of the Mississippi Valley," by Squier and Da-

vis, forming the first volume of the "Smithsonian Contributions to Knowledge.") Other works of a sacred or religious origin, consisting of mounds of earth and stone of various sizes, but always regular shapes, are found in connection with those above described, and are very numerous. They are oftenest square, terraced, and ascended by graded ways; sometimes hexagonal, octagonal, or truncated, and ascended by spiral paths, in most respects coinciding with the *teocallis* of Mexico and the *topes* of India—the high altars, symbolical in form, on which the priests offered up sacrifices, and paid adoration to the solar god. Some of these arrest our attention by their geometrical accuracy of form, and others by their great size, covering several acres of ground, and rising to imposing altitudes. A mound of this description, on the plain of Cahokia, Illinois, opposite the city of St. Louis, is 700 feet long by 500 feet broad at the base, and 90 feet high, covering upward of eight acres of ground, and having 20,000,000 cubic feet of contents. These mounds frequently contain skeletons. The most common monuments in the Mississippi valley, however, are those which are incontestably simple places of sepulture, memorials raised over the dead, and in their size probably bearing a certain relation to the importance when living of the personages over whom they were erected. Some of these, like that at Grave Creek near Parkersburg in West Virginia, and that at Miamisburg in Ohio, the one 70 and the other 68 feet in vertical height, no doubt mark the graves of personages of high consequence among the builders of these monuments. It sometimes happens that one of these sepulchral mounds contains two or more skeletons, but they rarely cover more than one, except in cases where the later Indian tribes, with a

Conical Mound, Marietta, Ohio.

vague notion of their sanctity, have buried their dead in them. The early white settlers also occasionally buried in them. The notion that

they contain vast heaps of slain, and are memorials of great battles, is unsupported by facts. Still more remarkable earthworks are those

Animal-shaped Mounds, Wisconsin.

commonest in Wisconsin and Iowa, but of which a few examples are found in Ohio, and which bear the outlines of men and animals, constituting huge bass-reliefs on the surface of the earth. One of these, surveyed by Squier and Davis in 1846, on the banks of Brush creek, Adams county, Ohio, is in the form of a serpent, over 1,000 feet in length, extended in graceful curves, and terminating in a triple coil at the tail. The embankment constituting

Serpent-shaped Mound, Adams County, Ohio.

the effigy is upward of 5 feet high by 30 feet base at the centre of the body, diminishing somewhat toward the head and tail. The neck

of the figure is stretched out and slightly curved, and its mouth is opened wide, as if in the act of swallowing or ejecting an oval figure, which rests partly between the distended jaws. This oval is formed by an embankment 4 feet high, and is perfectly regular in outline, its transverse and conjugate diameters being 103 and 39 feet respectively. The combined figure has been regarded by some as a representation of the oriental cosmological idea of the serpent and the egg. With the remains of the dead in the sepulchral mounds, as also within those which are believed to have been connected with the religion of their builders, many relics of art have been discovered, displaying greater skill than was known to exist among the tribes found in occupation of the country at the time of the discovery. Elaborate carvings in stone, pottery often of elegant design, articles of use and ornament in metal, silver, and native copper from Lake Superior, mica from the Alleghanies, shells from the gulf of Mexico, and obsidian, probably also porphyry, from Mexico, are found side by side in the same mound. Articles of comparatively recent date, some of them of undoubted European origin, have also been found among the later and secondary deposits in the mounds. Forged inscriptions, stones bearing mysterious characters, "Erse, ancient Greek, Phœnician, Celtiberic, and Runic," as evidences of every possible and impossible theory of American origin, have each found people credulous enough to accept and defend their authenticity, even after the authors of the various impostures have abandoned them to their fate. The facts connected with the monuments of the Mississippi valley "indicate that the ancient population was numerous and widely spread, as shown from the number and magnitude of their works, and the extensive range of their occurrence; that it was essentially homogeneous in customs, habits, religion, and government, as appears from the great uniformity which the works display, not only in respect to position and form, but in all minor particulars; and that the features common to all the remains identify them as appertaining to a single grand system, owing its origin to a family of men moving in the same general direction, acting under common impulses, and influenced by similar causes." Whatever differences the monuments display are such as might result from the progressive efforts of a people in a state of development, or from the weaker efforts of colonies, or what might be called provincial communities. It is impossible that a population for whose protection such extensive military works were necessary, and which was able to defend them, should not have been eminently agricultural; and such monuments as the mounds at Grave Creek and Cahokia indicate not only a dense agricultural population, but a state of society essentially different from that of the existing race of Indians north of the tropic. There is not, and there was not at the period of the discovery, a single

tribe of Indians, north of the semi-civilized nations of Mexico and Central America, which had the means of subsistence to enable them to supply for such purposes the unproductive labor necessary for the work; nor were they in such a social state as to compel the labor of the people to be thus applied. As regards the antiquity of these monuments, apart from such facts as a total absence of any reasonable traditions as to their origin among the Indians themselves, and the existence of the largest and most ancient forest trees on the embankments and in the ditches of the various works, there are other facts which enable us to arrive at approximate conclusions upon this point. None of these works occur on the lowest formed of the river terraces which mark the subsidence of the western streams; and as there is no good reason why their builders should have avoided erecting them on that terrace, while they raised them promiscuously upon all the others, it seems to follow that this terrace has been formed since these works were erected; a conclusion supported by the important fact that some of them have been in part destroyed by streams which have since receded for half a mile and upward, and which under no present possible rise, from rains or other natural cause, could reach the works again. Upon these premises, the time since the streams have flowed in their present courses may be divided into four periods, corresponding to the four terraces which mark the eras of their subsidence, of which period the last and longest (since the excavating power of the streams diminishes as the square of their depth increases) has elapsed since the race of the mounds flourished. Another fact bearing upon the question of the age of these works is the extremely decayed condition of the human remains found in the mounds. Considering that the earth around the skeletons is for the most part wonderfully compact and dry, and that the conditions for their preservation are exceedingly favorable, while they are in fact in the last stage of decomposition, we may form some approximate estimate of their remote antiquity. In the barrows of the ancient Britons, in a moist climate and under unfavorable conditions as regards preservation, entire and well preserved skeletons are often found possessing an undoubted antiquity of at least 1,800 years. From these and other facts and circumstances equally conclusive, we may deduce an age for most of the monuments of the Mississippi valley of not less than 2,000 years. By whom built, and whether their authors migrated to remote lands under the combined attractions of a more fertile soil and more genial climate, or whether they disappeared beneath the victorious arms of an alien race, or were swept out of existence by some direful epidemic or universal famine, are questions probably beyond the power of human investigations to answer.—The principal remains of antiquity in Mexico are the ruins of temples and of structures dedicated

to defensive purposes. Those of undoubtedly high antiquity are most massive in character, and display remarkable evidences of taste and skill. It would seem that during the aboriginal rule the bulk of the inhabitants dwelt in rude structures of thatch and cane, which after a few years of abandonment would decay and leave no trace of their existence, except perhaps in the fragments of broken pottery which might surround them. Whatever of architectural skill the people possessed was dedicated to the construction of their temples and the residences of their chiefs, which were often included the one within the other. These temples were in nearly all cases pyramidal in form, terraced and truncated, and ascended by flights of steps usually built on an inclined plane running up the centre of one of the sides, generally that opposed to the rising sun. These structures perhaps better deserved the name of altars, or the Scriptural name of "high places," than of temples; an edifice built on the level summit in reality constituting the *naos*, or temple

Mexican Teocalli.

proper. The great temple of Mexico, which is described by all the early writers as nearly identical in form and structure with all the temples of Anahuac, consisted of an immense square area, "surrounded by a wall of stone and lime eight feet thick, with battlements ornamented with many stone figures in the form of serpents." The extent of this enclosure, which occupied the centre of the ancient city, may be inferred from the assertion of Cortes that it might contain a town of 500 houses. It was paved with polished stones, so smooth, says Bernal Diaz, that "the horses of the Spaniards could not move over without slipping." The four walls of this enclosure corresponded with the cardinal points, and gateways opened midway upon each side, from which, according to Gomera, led off broad and elevated avenues or roads. In the centre of this grand area arose the great temple, an immense pyramidal structure of five stages, faced with stone, 300 feet square at the base and 120 feet high, truncated, with a level summit, upon which

were situated two towers, the shrines of the divinities to whom it was consecrated. It was here that the sacrifices were performed and the eternal fire was maintained. One of these shrines was dedicated to Tezeatlipoeca, the other to Huitzilipoeltli; which divinities sustained the same relation to each other in the Mexican mythology as Brahma and Siva in that of the Hindoos. Besides this great pyramid, according to Clavigero, there were 40 similar structures, of smaller size, consecrated to separate divinities; one was called Tezacalli, which was covered with brilliant materials, and sacred to Tezeatlipoeca, the god of light, the soul of the world, the vivifier, the spiritual sun; another to Tlaloc, the god of water, the fertilizer; another to Quetzalcoatl, said to have been the god of the air, whose shrine was distinguished by being circular, "even," says Gomera, "as the winds go round about the heavens; for that consideration made they his temple round." Besides these, there were the dwellings of the priests (amounting, according to Zarate, to 5,000) and of the attendants in the temples, seminaries for the instruction of youth, and, if we are to credit some accounts, houses of reception for strangers who came to visit the temple and see the grandeur of the court; also ponds and fountains, groves and gardens, in which flowers and "sweet-smelling herbs" were cultivated for use in certain sacred rites, and for the decoration of the altars. "And all this," says Solis, "without retracting so much from that vast square, but that 8,000 or 10,000 persons had sufficient room to dance in it, upon their solemn festivals." The area of this temple was consecrated ground; and it is related of Montezuma that he only ventured to introduce Cortes within its sacred limits after having consulted with the priests and received their permission, and then only on the condition, in the words of Solis, that the conquerors "should behave themselves with respect." The Spaniards having exhibited, in the estimation of Montezuma, a want of due reverence and ceremony, he hastily withdrew them from the temple, while he himself remained to ask the pardon of his gods for having permitted the impious intrusion. There is a general concurrence in the accounts of this great temple given by the early authorities, among whom are Cortes, Diaz, and others, who witnessed what they described. They all unite in presenting it as a type of the multitude of similar structures which existed in Anahuac. Their glowing descriptions, making due allowance for the circumstances under which they wrote, are clearly sustained by the imposing ruins of Papantla, Xoxachalco, Misanfla, Quemada, and the thousand other monuments which are yet unrecorded by the antiquary. Solis speaks of eight temples in the city of Mexico of nearly equal grandeur with that above described, and estimates those of smaller size to amount to 2,000 in number, "dedicated to as many idols of different names, forms, and attributes."

Torquemada estimates the number of temples in the Mexican empire at 40,000, and Clavigero places the number far higher. "The architecture," he adds, "of the great temples was for the most part the same with that of the great temple of Mexico; but there were many likewise of a different structure, composed of a single body in the form of a pyramid, with a staircase, &c." Gomera says, "They were almost all of the same form; so that what we shall say of the principal temple, will suffice to explain all the others." Cortes, in a letter to Charles V., states that he counted 400 of these pyramidal temples at Cholula. From all sources we gather that the principal temples, or rather sacred places, of Mexico consisted of large square areas, surrounded by walls, with passages midway at their sides, from which avenues or roads sometimes led off; and that within these enclosures were pyramidal structures of various sizes, dedicated to different divinities, as also the residences of the priests, with groves, walks, and fountains. It has already been said that the pyramids of Teotihuacan, which are found within eight leagues of the city of Mexico, on the plain of Otumba, are probably among the most ancient monuments of Mexico. There are two principal ones, dedicated, according to tradition, to the sun and moon respectively; each built of cut stone, square, with four stages and a level area at its summit. Humboldt says the larger is 150 feet and the smaller 145 feet high. Mr. Brantz Mayer, however, affirms that the larger is 171 feet high; Mr. Glennie, 221 feet. It is 680 feet square at the base, covering an area of 11 acres, or nearly equal to that of the great pyramid of Cheops in Egypt. The pyramid of Cholula also has four stages, and when measured by Humboldt was 160 feet high by 1,400 feet square at the base, covering an area of 45 acres.—The temples of Central America, of which so many ruins still exist, although possessing a general correspondence with those of Mexico, had nevertheless many features peculiar to themselves. The artificial terraces or pyramidal elevations seem to have been usually less in size, but crowned with more extensive buildings, upon which aboriginal art exhausted its utmost capabilities. These structures were marked by broad stairways, leading directly to their principal entrances. Upon some of these terraces a single building was erected, but upon the larger ones several (usually four) were arranged so as to form a court or area. They were massively built, the walls being in all cases of great thickness. The larger number were one story high; but there were many of two, and some of three or more stories. In these cases, each successive story was usually smaller than that below it, giving the structure the appearance of a pyramid of several stages. The fronts of these buildings, though sometimes stuccoed, were usually of stone, and covered with elaborately carved figures and ornaments, many of them

without doubt symbolical. The interiors of some corresponded with the imposing character of their exteriors. They were divided into

Pyramidal Temple, Palenque.

narrow corridors and dark chambers. These were arched, or rather the roofs were supported by overlapping courses of stones—constituting a pointed arch, corresponding in type to the earliest monuments of the old world. The walls of these corridors were often stuccoed,

Monolith, Copan.

and covered with paintings and figures in bas-relief. Within some of the chambers, as at Palenque, have been discovered tablets clearly of a

mythological character, covered with elaborate and artistic sculptures and hieroglyphics. In these chambers are still found the remains of idols and altars, and evidences of ancient sacrifices. The works of Stephens, Catherwood, Squier, Brasseur de Bourbourg, and Charney contain full accounts of these monuments.—In Honduras, at Copan, the remains of edifices are found, corresponding generally with the preceding description, but associated with grand monoliths, intricately carved, such as have been discovered nowhere else except at Quirigua, in the vicinity of Copan, and on the islands of Lake Nicaragua. They seem to have been planted in the areas, perhaps also on the steps and summits, of the ancient structures. Whether designed as statues of the gods of ancient worship, or to commemorate distinguished priests, warriors, or statesmen, can probably only be determined when the hieroglyphical inscriptions which some of them bear shall have been deciphered. To Copan we may safely assign an antiquity higher than to any of the other monuments of Central America with which we are acquainted, except those rude works of earth and uncut stone which also exist there, and which seem to have been the early types after which, as civilization and the arts advanced, the more imposing monuments of which we have spoken were modelled. It is certain that Copan was a ruin, concerning which only the vaguest traditions existed, at the period of the Spanish conquest.—In New Granada, among many minor relics of antiquity, such as figures of divinities and objects worked in gold and stone, are found a few considerable monuments, consisting of structures which seem to have been supported by columns of large size and just proportions.—In Peru we find a very large number of aboriginal monuments, consisting not alone of ruined temples, but of great works of public utility—aqueducts, bridges, and paved roads hundreds of miles in length. The remains of the great temple of the sun at Cuzco are still imposing. In describing it as it existed at the time of the conquest, the early Spaniards expended every superlative of their language. It consisted of a principal building and several chapels and inferior edifices, covering a large extent of ground, in the heart of the city. Aqueducts opened within this sacred enclosure; and it contained gardens, and walks among shrubs and flowers of gold and silver, made in imitation of the productions of nature. It was attended by 4,000 priests. "The ground," says La Vega, "for 260 paces around the temple, was considered holy, and no one was allowed to pass within this boundary but with naked feet." Nor even under these restrictions were any permitted to enter except of the blood of the incas, in whom were centred the priestly and civil functions of the government. Besides the great temple of the sun, there was a large number of inferior temples in Cuzco, estimated by Herrera at 300. Nu-

merous others are scattered over the empire, all of which seem to have corresponded very nearly in structure to that already described.

Remains of Temple of the Sun, Cuzco, Peru.

The one most celebrated, next to that of Cuzco, was that of Pachacamac, which contained a considerable town, the grand pyramidal shrine of the divinity Pachacamac, and, after the conquest of the coast by the incas, a temple of the sun and a convent of the vestals of the sun, the whole surrounded by a wall of several miles in extent. According to Roman, who speaks, however, with little authority, "the temples of Peru were built upon high grounds or the tops of hills, and were surrounded by four circular embankments of earth, one within the other. The temple stood in the centre of the enclosed area, and was quadrangular in form." A structure corresponding very nearly with this description is noticed by Humboldt, who denominates it, in accordance with local traditions, *Ingapilca*, "House of the Incas," and supposes it to have been a sort of fortified lodging place of the incas, in their journeys from one part of the empire to the other. It is situated at Cannar, and occupies the summit of a hill. The "citadel" is a very regular oval, the greatest axis of which is 125 feet, and consists of a wall, built of large blocks of stone, 16 feet high. Within this oval is a square edifice, containing but two rooms, which resembles the ordinary stone dwellings of the present day. Surrounding these is a much larger circular enclosure, which, from the description and plate, we infer is not far from 500 feet in diameter. This series of works possesses few military features, and it seems most likely that it was a temple of the sun. This opinion is confirmed by the fact that at the base of the hill of Cannar was formerly a famous shrine of the sun, consisting of the universal symbol of that luminary

formed by nature upon the face of a great rock. Ulloa describes an ancient Peruvian temple, situated on a hill near the town of Cayambe, perfectly circular in form and open at the top. It was built of unburnt bricks, cemented together with clay. The most wonderful and probably among the most ancient monuments of Peru (or rather Bolivia, formerly Upper Peru) are those at Tiahuanaco, already referred to, on the shore of Lake Titicaca. Their origin is lost in obscurity, and they are supposed by many writers to have been the work of a race anterior to the incas, denoting perhaps a more advanced civilization than the monuments of Palenque. They have been described by a number of the early writers, commencing with Pedro de Ceiga, one of the followers of Pizarro, in whose day their ruins seem to have differed but slightly from what they are now. The latest and probably the most exact account of these enigmatical remains is that of Mr. Squier, who spent several weeks in their investigation in 1864. He describes them as situated in a broad, open, arid plain, cold in the wet and frigid in the dry season, where no cereals will ripen, the only production fit for human use being a variety of small bitter potato. The monuments consist of rows of erect stones, some of them rough or but rudely shaped by art; others accurately cut and fitted in walls of admirable workmanship; long sections of foundations with piers and portions of stairways; blocks of stones with mouldings, cornices, and niches cut with geometrical precision; vast masses of sandstone, trachyte, and basalt, but partially hewn; and great monolithic doorways, carved from single blocks of stone, and bearing symbolical ornaments in relief, besides smaller rectangular, and symmetrically shaped stones, rising on every hand or scattered in confusion over the plain. The central and most conspicuous portion of the ruins is a great rectangular mound of earth, 650 feet long, 450 wide, and now about 50 feet high. It was originally terraced, each terrace being faced by a massive wall of cut stones, artfully dovetailed and clamped together, and had on its summit various stone edifices. This mound, which is called "the fortress," has on its E. side an apron or dependent platform, 320 x 180 feet. A short distance to the N. of this mound is what is called "the temple," a rectangle of 445 by 388 feet, defined by lines of erect stones, some entirely rude, and others apparently partially shaped by art. They support a terreplein of earth, on which are traces of structures, and on the E. side of which are ten great stone pilasters, suggestive of Stonehenge, perfectly alligned, and of varying sizes; the largest being 14 feet high above ground, by 4 ft. 2 in. broad and 2 ft. 8 in. thick. Near "the temple" are the foundations of what is called "the palace," the piers which supported the walls being of hard trachyte admirably cut, in this respect equalling the finest stone work of ancient or modern times. Be-

sides these there is an enclosure called "the hall of justice," rectangular, 420 by 370 feet, within which are the ruins of a nameless structure, "sanctum sanctorum," 131 by 23 feet, composed of massive stones beautifully cut, some of which are 25½ feet long by 14 broad, and 6 ft. 6 in. thick, held together by bronze clamps. A distinguishing and peculiar feature of the remains at Tiahuanaco are a number of monolithic doorways, the largest of which is 13 ft. 5 in. long by 7 ft. 2 in. high above ground, and 18 in. thick. Through its centre is cut a doorway 4 ft. 6 in. high above ground, and 2 ft. 9 in. wide, above which, on its S. E. front, are four lines of sculpture in low relief, and a central figure immediately over the doorway in high relief. On the reverse the doorway is surrounded by friezes or cornices, with ornamental niches, &c. Besides these remains there are innumerable others of massive proportions, covering fully a square mile, of which it would require many pages to give an intelligible description, even with the aid of cuts and plans. Mr. Squier is disposed to rank the great areas at Tiahuanaco, surrounded with upright stones, with those vast open temples like Stonehenge and Avebury in England, and of which examples are found in other parts of the world. Looking to the cold, barren region in which these remains occur, so ill adapted to the support of any considerable population, Mr. Squier fails to regard them as relics of an ancient capital or seat of dominion, but of a sacred spot or shrine, the position of which was determined by an augury, an incident, or a dream. Certain it is, they were ruins at the time the inca conquerors swept over the Collao. Mr. Squier was the first to make known the existence, in the great Andean plateau, of a class of rude lithic and megalithic monuments, generally regarded, throughout the world, as the earliest efforts of human art. These consist of circles, defined by uncut stones, which in Scandinavia, the British islands, France, and northern and central Asia, have been loosely designated as "sun" or "Druidical" circles; also of piles of rough stones coincident in style and character with the cromlechs, dolmens, &c., of the same regions. On the bare mountain tops of High Peru are hundreds and thousands of enclosures or fortresses, *puucas*, antedating all history, which were built, according to Peruvian tradition, when the country was divided up into warlike and savage tribes, "before the sun shone," or the incas had established their beneficent rule. They strongly resemble the remains which in Europe are uncritically known as Pelagic. They are held in great reverence, as the works of giants whose spirits still haunt them, and to whom offerings of various kinds are still made. The symbolic character of the stone circles may be inferred from the name they still bear, *intihuatani*, places where the sun is arrested or tied up. There is another class of monuments also antedating the incas,

the *chulpas* or burial towers, presumably of the ancient Aymaras. Some of these are round, others square, of varying proportions, from 15 to 40 feet high; sometimes constructed of elaborately cut stones, in other cases of high stones stuccoed over, and all containing inner chambers in which the dead were deposited, generally in niches in the walls, or in cists beneath the foundations. The remains of inca art are numerous and imposing. A considerable portion of the gorgeous temple of the sun in Cuzco is still extant; the great cyclopean fortress of Saesahuaman that dominates the city of the sun, and in storming which Juan Pizarro lost his life, is almost as perfect as it was three centuries ago; the mountain stronghold of Pisac challenges our admiration by the rare engineering skill it displays, as well as by its massiveness and extent, covering as it does miles of area; Ollantimbo, wrought in polished porphyry, is a marvel of aboriginal art; while the palace of the vestal virgins on the island of Coati in Lake Titicaca, the terraced mountains, the vast *acequias*, and the paved roads thousands of miles long, all attest the power and beneficence of the incas. The Peruvian empire was a concretion of families, tribes, or nationalities, reduced by conquest, and their monuments, especially on the Pacific coast, as Europeans found them, have few resemblances and no identities with those of the elevated interior whence the inca race descended. Among the most important of the coast nations were the Chimus, who held wide sway, with their capital, at what is now called Grand Chimu, or Mansiche, near the town of Truxillo, founded by Cortes, in what is known as northern Peru. They were subjugated by the incas at a period not easily definable, after a long and bloody struggle, and their capital given up to barbaric ravage and spoliation. But its remains exist to-day, the marvel in many respects of the southern continent, covering not less than 20 square miles. Tombs, temples, and palaces arise on every hand, ruined but still traceable. Immense *huacas* or pyramidal structures, some of them half a mile in circuit; vast areas shut in by massive walls, each containing its water tank, its shops, municipal edifices, and the dwellings of its inhabitants, and each a branch of a larger organization; prisons, furnaces for smelting metals, and almost every concomitant of civilization, existed in the ancient Chimu capital. One of the great *huacas*, or pyramidal edifices, called "the temple of the sun," is 812 feet long by 470 wide at the base, and about 150 feet high. Another, "El Obispo," is nearly equal in size. These vast structures have been ruined for centuries; but the work of their excavation is still going on. From one of them, called that of Toledo, a Spanish explorer of that name in 1577 took \$4,450,284 in gold and silver.—As already observed, most of the monuments of antiquity in America seem to be the ruins of temples, places of worship, or edifices in some way con-

nected with the religion and superstitions of their builders. Throughout they sustain many and obvious resemblances, consisting of elevated platforms or truncated pyramids, ascended directly by broad flights of steps, or circuitously by winding paths; they scarcely differ except in the materials of which they are constructed, or the greater labor and skill displayed upon them. The builders of the temple mounds of the Mississippi valley seem to have been governed by the same principles which controlled the architects of the majestic *teocallis* of Mexico; their ruder structures being only the evidences of their ruder or earlier state. Instead of being faced with stone, elaborately carved with the symbols of their religion, the green turf covered the high places of the mound-builders; they ascended them by graded avenues or winding paths, not by broad and imposing stairways; and the wooden temple roofed with bark supplied the place of the massive edifices which still rear their crumbling, spectral fronts amid the forests of Central America. The features of resemblance between a large part of the monuments of America and many of the most ancient of those of the old world early attracted the attention of Humboldt, who seems to have been strongly impressed with their identity, yet, with characteristic caution, unwilling to follow the connections to their ultimate results. That the practice of erecting these colossal, montiform temples was necessarily derivative, cannot be admitted. The primitive temples of every people on the globe seem to have been constructed much upon the same plan, and consisted of great enclosures of earth or upright stones, often, if not always, symbolizing in their forms the leading conceptions connected with the worship to which they were dedicated. The primitive altars, or shrines of the heathen gods, corresponded in rudeness and size with their vast open temples, and like them sustained everywhere a general resemblance. This resemblance to a certain degree may be regarded as accidental, inasmuch as an eminence or high place would naturally suggest itself as the most fitting spot whereon to render up homage to those superior powers which were supposed to dwell above, in the skies, or among the stars. It may also have resulted in no small degree from the very general primitive superstition that mountains and hills were the abiding places of the gods.

AMERICAN INDIANS. When America was discovered by Columbus, it was supposed by him and his contemporaries to be a part of the region vaguely termed India beyond the Ganges; and the newly discovered lands were thenceforth styled Indies, and the native inhabitants to this day are called Indians. The names by which Indian tribes are known to us are a strange medley. Some are nicknames given by the whites, such as Hurons, Iroquois, Nez Percés, Gros Ventres, Diggers, Blackfeet, Flatheads; others are derived from some locality near which they were resided, as the Delawares,

River Indians, Montagnais, Athabascans, &c. A great many tribes are known to us by the names applied to them by other Indian tribes. Thus the words Mohawk, Sioux, Esquimaux, Assiniboins, Arkansas, and Nottoway are not the real names of tribes, but all Algonquin terms; so too Adirondacks is the Mohawk term of contempt for the Montagnais on the St. Lawrence. As a general rule Indians when asked their name give the term Men or Real Men. This is the meaning of Onkwe Honwe, used by the Hurons and Iroquois; Renappi, Lenni, Illiniwek, Irini, Nethloweck, used by the Algonquin tribes; Tinne, used by the Athabascans; and apparently of Apache. But this meant the tribe as composed of individuals; each tribe as a unit, a body politic, had a name, generally that of the animal or object which was the totem of the tribe. Thus the five Iroquois nations were called as one Hotinnosionni or Hodenosaunee, a cabin; the Mohawk was the Gannigwari, the she bear; the Illinois were called Anoka.—The whole continent was occupied by scattered tribes, from the lowest stage of barbarism to a semi-civilized state, corresponding to the stone and bronze ages of the old world, for iron was nowhere wrought. Agriculture was confined to a few plants—maize, squashes, beans, tobacco, plantains, cassava, &c. Manufactures were confined to the making of canoes from bark or hollowed trees, lodges of bark or skins, garments of skins, and in some parts basket work and rude weaving, weapons, and images carved and occasionally hammered or moulded. There seems to be an identity of race throughout the continent. Lawrence gives their general character as follows: skin brown or cinnamon-hued; iris dark; hair long, black, and straight; beard scanty; eyes deep-seated; nose broad, but prominent; lips full and rounded; and face broad across the cheeks, which are prominent, but less angular than in the Mongolian, and with the features distinct. The general shape of the head is square, with low but broad forehead, back of head flattened, top elevated, face much developed, and powerful jaws. The parietal region is much developed, the orbits are large, the feet and hands small and well proportioned, and the teeth white and sound; the facial angle about 75°. The average stature is no greater than in other races. The muscular development is not great, and there is a tendency to grow very fat when food is abundant and the habits of life are lazy. Though active and agile in sports and pursuits of short duration, the Indian is inferior to the white race in labors requiring compactness of muscle and long-continued exertion. The complexion varies from the dark brown of the California tribes to the almost white of the Mandans and the Chinooks. The beard is scanty, except among the Athabascans, and is prevented from appearing by the custom of plucking it out. The Indian has a dull, sleepy, half-closed eye, with little fire,

unless when the passions are excited. The features are frequently regular, and the expression noble; many of the women are handsome. The skin is thinner, softer, and smoother than in the white races. The practice of artificially moulding the skull was often adopted. The average volume of the brain, as measured in nearly 650 crania, is only 77 cubic inches for the semi-civilized and 84 for the barbarous tribes. Dr. Morton, from a scientific examination of skulls from existing tribes and ancient tombs, considers the American nations, excepting the polar tribes, as of one species and one race, but of two great families, which resemble each other in physical but differ in intellectual character. The North American Indian was of haughty demeanor, taciturn, and stoical to the last degree; cunning and watchful in the surprise, persevering in the pursuit, and revengeful in the destruction of his enemies; cruel to prisoners of war, without regard to age or sex, and when himself a captive enduring the most painful tortures without a murmur; brave and too often ferocious in war; idle and grave in peace, except when engaged in hunting and amusements; hospitable, and grateful for favors; of necessity a close observer of natural phenomena, his temperament poetic and imaginative, and his simple eloquence of great dignity and beauty of expression. As a race, however, the animal propensities strongly preponderate over the intellectual.—The origin of the American Indians has been a matter of debate for centuries, and Grotius, De Lact, Garcia, and others discussed it in their day with more learning than judgment. During the last century and early in this a number of writers, treating many early usages of mankind as peculiarly Jewish, endeavored to prove the Indians to be descended from the ten tribes. Others, with as little foundation in facts, endeavored to derive them from the Welsh, the Mongols, or Malays. The tribes of North America regarded themselves as comparatively recent occupants of the soil. The Algonquins and Iroquois had traditions of their journey eastward: the Algonquins styled the Dakotas men of the salt water, and, being pressed eastward by them, repelled their advance. The Athabascans kept up the remembrance of their emigration across the Pacific; the Choctaws came from the northwest, and the Mexicans are generally supposed to have come from the north, though the latest theories assign to them a southern origin. All this pointed to the northwest, where the abundance of fish made a natural halting spot for tribes till they were driven south by a new emigration. The Huastecas seem the first moving northward. While language fails to connect them with any Asiatic families, their modes of life and implements are thought to connect them with all the earlier races of the eastern continent whose relics are found in mounds and shell heaps.—The most civilized parts when discovered by Europeans were those ex-

tending from New Mexico to Peru. There permanent architecture prevailed, the work of the occupants or of a previous race, the finest specimens being in the Maya region and in Peru, and the least enduring the adobe buildings of the Gila and Rio del Norte. Out of the limits of this district nothing but the most perishable structures were raised, the only monuments being mounds, often peculiar and apparently symbolical in shape. The inhabitants were divided into a number of tribes, whose natural state seemed to be that of war. The Esquimaux in the north were warily clad in furs, and lived in close huts of snow or dug into the earth. The sea furnishing their subsistence, they invented peculiar boats, spears, and means for kindling and preserving fire. Below them, the wild tribes covering most of British America and the United States were hunters and fishers, giving little attention to agriculture, except among the Huron Iroquois, who raised maize, beans, squashes, and tobacco, and seem to have been the earliest who carried on any trade. In point of manufactures they were about equally advanced. All made pottery. The Iroquois bark lodges were superior to the tent-like hide huts of the Algonquins, but the latter excelled in the manufacture of the ingenious snow shoes and in canoe building, the Iroquois using elm bark, the Algonquins birch. The Dakotas excelled in the manufacture of stone pipes, and the Pacific tribes in that of baskets, some so closely woven as to hold water. The Rocky mountains furnished a sheep whose wool several tribes learned to spin and weave. In point of progress the Cherokee and Choctaw Muscogees resembled the northern tribes. The Natchez were the first tribe going south who seem to have had anything like a temple for worship. The Pueblo Indians of New Mexico had towns, built with a dead wall without for protection, rising several stories, and entered by ladders. They had also temples, and cultivated the soil. The Mexican and Peruvian tribes were still further advanced; their range of manufactures and cultivated plants was greater; their means of perpetuating the memory of events better. At the north the rudest hieroglyphics formed the only means, the Micmacs in Nova Scotia having the most distinct system, and the only one which Europeans were able to adopt and employ; but the Mexicans had a system of picture writing of which enough has been preserved and explained to give us an insight into their history. The Peruvians at first had a system of recording by *quipos* or knotted cords, which, like the wampum belts of the north, seem to have been merely aids to the memory. The uncivilized tribes of South America, embracing the large families of the Caribs on the north, the Tupi-Guaranis on the east, and the Araucanians on the south and west, closely resembled in their state of advancement the wild tribes of the northern portion of the continent.—None of these tribes seem to have domesticated any

animal except the dog, and among the Peruvians the llama. In no part consequently were there tribes leading a pastoral life, depending on their flocks and herds. Game was taken by shooting with the bow and arrow, or by means of darts or spears; smaller animals were taken by traps. Where game was very abundant, it was sometimes driven into a sort of park and slaughtered. The South American Indians used a blowpipe for small game, and the southern tribes used the lasso and stone balls attached to hide ropes. Fish was taken by nets or speared, and in some parts the fish in lakes were captured by throwing into the water vegetable matter that caused a kind of intoxication. The only beverage of the northern tribes was water, but the Mobilian tribes had their black drink, or *cassine*. In Mexico *pulque*, the fermented sap of the mescal or maguey, furnished an intoxicating drink; and in South America a similar drink was the *cauim*, made from the cashew and other fruits subjected to fermentation. All tribes were fond of painting and tattooing their persons, the paint being varied for grief or joy, war or peace. They used as adornments beads made of clam shells, feathers, porcupine quills, and parts of birds and animals. The dress of the hunter tribes was simple, consisting of a robe and breech cloth for the men and a short petticoat for the women; in the warmer parts this petticoat was often a mere fringe of moss or other vegetable matter, and men went entirely naked. The use of tobacco, generally mixed with willow (hence *kinnikinnick*, a mixture), was almost universal among the Indian tribes, and has spread over the world. It was introduced at all their important assemblies, and the Mississippi tribes made the pipe the symbol of peace, a usage which spread to other parts of the country. The word *calumet*, a French Canadian corruption of *chalumear*, has been adopted to designate this national pipe. In Peru the leaves of the coca chewed with quicklime, just as the East Indians chew the areca nut and betel palm, produced the same narcotic and stimulating effects. The amusements of the Indians were the athletic exercises, running, leaping, paddling, games of ball, games with small stones, some quite complicated, and dances. These last were numerous, and entered into religious observances and preparations for war, as well as merrymakings. The sexes generally danced apart. Boys were trained from the time they left the cradle to feats requiring dexterity and courage. The probation of the young warrior was attended in some tribes with long fasts and rigorous tortures; and he acquired a name and a recognized position in the tribe only on his return from his first expedition or battle. War was carried on rather by treachery and surprise, and by small bands, than by set battles or large armies. Those who fell were in the north scalped, the hair of the head with the skin being torn off as once practised in the eastern continent. Prison-

ers were either adopted and naturalized or tortured. Government was of the slightest kind. Kings and hereditary chiefs were found in some tribes; ability in others raised a man to command. Laws there were none, or courts, or judicial sentences, except among the more civilized in Mexico and Peru. The manner of making fire in different parts varied, from rubbing two pieces of wood or cane to ingenious machinery by which a revolving stake finally gave a blaze. The tribes believed in a future state of existence, and paid great attention to the bodies of the dead, in some cases collecting their remains after a certain number of years and burying them with choice objects in fur-lined trenches, with games, and celebrations. Food was placed on the graves of the dead, and implements of the chase for use in the next world. They recognized a supreme being, and a host of spirits good and evil, the latter especially to be propitiated. The idea of sacrifice was apparently universal, and animals and human beings were offered, the former as substitutes for the latter. Cannibalism, except where impelled by necessity, was apparently connected with religious ideas. Being firm believers in the power of evil spirits, they ascribed disease and defeat to their malign influence; and the medicine men, who were supposed to counteract these, were resorted to in sickness, and when starting on the war path, the hunt, or long and perilous journeys by land or water. Dreams exercised a great influence over them, and may be considered a part of their religious system. They regarded them as manifestations of cravings of the soul, the non-gratification of which would be attended with serious injury to the whole man. Tribes were divided into clans, and as a rule no man could marry in his own clan, and the children followed the clan of the mother. The scheme of relationship was curious and complex. Woman was in a degraded state. She did all the work except war and hunting. She tilled the earth, and bore all burdens. Parturition was attended with little pain. Cooking was simple, and without seasoning. Baking was done in holes in the ground, and water was boiled by throwing heated stones into it. The common plan was to roast over the fire. Corn was parched, and was the food used while travelling, being often hidden in holes marked so as to be recognized. Some diseases introduced by the whites, such as smallpox, and alcoholic drink, have been singularly destructive and fatal. Disease was left to charlatans and superstitious treatment. The use of vapor baths was perhaps the most general and effective remedy. They employed as emetics thoroughwort, spurge, and Indian hemp; and as cathartics also the inner bark of the horse chestnut and butternut; as rubefacients, mayweed and waterpepper. They were acquainted with many poisons, which they used for self-destruction, the purposes of revenge, and in the more southern parts for poison-

ing their weapons. Blood-letting and cupping were not unknown. In asthma they smoked tobacco and drank infusions of spicewood, sassafras, and skunk cabbage; in coughs, slippery elm and mallow tea, and decoctions of the twigs of the pine and spruce; in renal affections, bear-berry, spicewood, and gooseberry root; in diarrheas of all kinds, decoctions of the low blackberry, cranesbill, hardhack, white oak bark, partridge berry, and American ipecacuanha or Indian physic (*gillenia*); in dropsy, the bark of the prickly ash and wild gooseberry, and externally a sweat in heated earth; in amenorrhœa, sassafras, spice, and wormwood decoctions; in hæmorrhage, powdered puff balls, and astringents firmly bound on the wound. Incised wounds they sewed together with strings from the inner bark of basswood or fibres from the tendons of deer; diseases of the skin were treated with yellow dock, and abscesses by poultices of onions.—In their intercourse with the Indians the Spanish government educated the sons of princes and chiefs and gave them rank as Spanish nobles, so that to this day distinguished families boast their descent from Mexican and Peruvian monarchs; and among those who governed Mexico as viceroys under the kings of Spain several bore the name of Montezuma. The lower orders of Indians were assimilated with those of the Spanish emigrants, and at an early period were admitted to the same civil rights. The wilder tribes were gradually formed to civilization by missionaries under the system of reductions, a presidio of soldiers being assigned to each. The children of the first converts soon mingled with the more civilized Indians. The consequence is that the great mass of the people of Spanish America are of Indian origin, some towns being almost exclusively so; and it would be almost impossible from our present data to give the exact Indian, white, and mixed population. The late president of Mexico, Juarez, was a pure Indian; and so have been many of the presidents of Central America. The number of wild tribes is consequently much less in proportion to the whole Indian population in Spanish America than in the United States. Of the missions on the plan of reductions the most famous were those of Paraguay.—The French, settling in Canada and subsequently Louisiana, had less civilized tribes to deal with; but they acquired a permanent ascendancy over them without wars. The Iroquois, occupying the present state of New York, were the great enemies of the French and their allies. French missionaries, however, repeatedly established missions even among the Iroquois, and the descendants of their converts form three towns in Canada. Missions began at the commencement of the French settlements among the Nasquapees, Montagnais, Algonquins, Chippewas, and Ottawas are still maintained among the surviving remnants of those tribes. New missions under Catholic and Protestant direction have been established

among the Crees, who had been incidentally reached by the old missionaries, and the Athabasean tribes and those in British Columbia and Oregon. The efforts of the French government to elevate the social condition of the Indians were unremitting; provision was made for their naturalization as citizens; but these efforts failed, although often renewed, and the most experienced gave up the task as hopeless. Their intestine wars were arrested, agriculture was introduced or improved slightly, and morality raised to a higher standard, so that they resemble the lower grade of peasantry, simple, indolent, and unambitious. Though some chiefs bore French commissions, and the convents educated some girls who became capable teachers and even entered religious orders as nuns, there is no example of men attaining admission to any civil profession. The diminution of game, destroyed for furs, and the influence of intoxicating liquors have steadily diminished the numbers of the Indians in the British possessions.—The English who colonized the present United States were not, like the colonists from Spain and France, under a system devised and maintained by the home government. There was no Indian policy, and between the English settlers and the natives there was a strong degree of incompatibility. From the moment the settlers were able to dispense with Indian aid in supplying Indian corn and game in return for trinkets or arms, down to the present day, the prevailing instinct of the Anglo-Saxon in America seems to have been to remove the Indian as far as possible from him. In the early times this influenced the austere religious Puritan of New England as much as it did the careless settler of Virginia. New England missions were early begun by the Mayhews on Martha's Vineyard and Nantucket, Eliot among the Naticks at Newton, Mass., Cotton and others at Plymouth, and Sergeant and his fellow laborers in Connecticut. But these efforts were almost entirely individual, and they have left us monuments of their zeal and ability in Eliot's Indian Bible and other works prepared for the converts. The most extensive efforts to Christianize the natives of what is now the United States were those starting from the French and Spanish colonies. The settlement of Florida was followed by permanent and beneficial missions among the Timuquas and Appalaches, which lasted till they were almost exterminated by the people of Carolina. Texas, New Mexico, and California were also seats of very extended missions, under which the Indians were instructed, preserved from evil influences, and made self-supporting. The Mexican revolution overthrew the system, and the whole structure was destroyed in a few years. The Pueblo Indians of New Mexico alone remain, much degenerated from their condition of a century ago. The French missions within our territory embraced those among the Abenakis of Maine, now represented by the Catholic

Penobscots and Passamaquoddies; among the Iroquois of New York, their converts finally removing to Canada and now found at Sault St. Louis, St. Regis, and Lake of the Two Mountains; among the Chippewas, Ottawas, Pottawattamies, Menomonees, Illinois (Kaskaskias, &c.), and Miamis (Weas, &c.). Those in Louisiana, among the Tonicas, Natchez, Choctaws, and Arkansas, seem to have produced little permanent good, except perhaps among the last. Maryland began missions coeval with its settlement, but the overthrow of the original plan of colonization put an end to them. About the beginning of the last century the English society for the propagation of the gospel in foreign parts began a new era. Missions arose among the Mohawks and in Virginia and Carolina. Dr. Wheelock's Indian school (afterward Dartmouth college) contributed to the work. The Brainerds labored in New Jersey and Pennsylvania. The efforts of the Moravians had still better results, and their Delaware mission was the most successful yet seen in the English colonies. During the present century far more has been done. The society of Friends took an active interest in Indian progress. The Episcopalians established an Oneida mission; the American board of commissioners for foreign missions, organized in 1810, established missions among the Cherokees, Choctaws, Ottawas, Chippewas, Chickasaws, Creeks, Dakotas, Pawnees, and Senecas, some of which were remarkably successful. Baptist missions were also established among several of these tribes. A Methodist society established in 1819 also founded Wyandot, Iroquois, Creek, Ottawa, Shawnee, Dakota, and Oregon missions; while the southern Methodists also created missions. The Presbyterians in 1837 began to labor among the Weas and other northwestern tribes, and among some of those in the Indian territory. The American missionary association, American Indian missionary association, southern Baptists, and Baptist home missionary society also entered the field. Their labors were not always permanent or well concerted, and frequent changes took place. Catholic missions arose among the Chippewas and Ottawas, under Bishop Baraga and others, among the Winnebagoes, the Pottawattamies and Osages, and in the Rocky mountains.—The French were able to maintain peace with all the Canadian tribes, while the English colonies were constantly at war. The first war between the English colonists and the natives occurred in Virginia in 1622, when the Indians under Opechanganough rose against the settlers to exterminate them. The colonists in a ten years' war reduced them at this time, and again in 1644; and in another war in 1675 they still more diminished the Indians. The New England wars began in 1637 with the destruction of the Pequods by the settlers of Connecticut and Massachusetts as allies of the Narragansetts, and the extermination of the Narragansetts in 1643 by the

New Englanders as allies of the Mohegans. In 1675 began the war with Philip, chief of the Wampanoags, in which nearly all the Indians were cut off or driven to a distance. Maryland enjoyed comparative peace, but was in 1675 with Virginia involved in a war with the Susquehannas. The Dutch at New Amsterdam at first maintained friendly relations with the Indians, but in 1643 became involved in wars in which the Indians lost severely. In the south, North Carolina in 1711 suffered terribly in a war with the Tuscaroras, who finally emigrated to New York; and South Carolina in 1715 was attacked by the Yemassee and a confederation of tribes on its frontier. The New England occupancy of Maine brought on new hostilities connected with the wars between France and England. The French in Canada proposed neutrality and an agreement to employ no Indians on either side. New York consented and was saved from the horrors of Indian war, which New England preferred. The New England forces, however, finally overthrew the Pennacooks and Norridgewocks and closed their Indian war. In the seven years' war, known in America as the French and Indian war, both sides used the Indians, and the annals of the time teem with horrors. The French had some wars with the Foxes and Miamis in the west, and provoking the Natchez, drew on themselves a massacre, followed by a war in which the Natchez were destroyed. The French then attacked the Chickasaws, but failed to subdue them. The Indians looked on the English success in Canada with jealousy, and Pontiac in 1763 organized a vast conspiracy of the Indian tribes, aiming at a total extirpation of the whites; but they were finally reduced, as were the Cherokees, who made war in 1760. In the course of these wars, Michilimackinac, and Forts St. Joseph, Ouiatenon, Miami, Presqu'isle, Leboeuf, and Venango, were taken by the Indians. Detroit besieged, and stubborn battles fought at Bloody Bridge, Fort Pitt, Bushy Run, and at Point Pleasant between the Virginians and Shawnees. When the American revolution began, the English government at once employed Indians, and the Iroquois and western tribes ravaged the frontiers. An expedition under Sullivan laid waste the territory of the Six Nations. The articles of confederation gave congress little power. Under the constitution of 1787 the general government claimed sovereignty over the whole territory, and had the management of Indian tribes not within a state and under laws and treaties with it. The United States treaties with Indians were made as with foreign powers. The great object to be obtained was the cession of the large tracts claimed as hunting grounds, sometimes on very slight pretexts. The Indian tribes viewed the new government with distrust, and the Miamis began hostilities in 1790, and in two engagements near the present Fort Wayne defeated the army under Gen. Harmar.

The next year they routed St. Clair's army, killing nearly half of his men; but they were reduced by Gen. Wayne in 1793. The war was renewed in 1811, when they were again defeated by Gen. Harrison at Tippecanoe. In the war with England that followed, the Indians aided the enemy and again ravaged the frontiers; but Harrison defeated the combined forces on the Thames in 1813, killing Tecumseh, the head of the great Indian confederacy; while in the south Jackson, in 1813 and 1814, humbled the Creeks at Tallushatchee, Talladega, and Tohopeka. In 1817 the Seminoles commenced hostilities, but were punished by Jackson, and Florida soon after became part of the United States territory. The next Indian trouble was that caused by the attempt of Georgia to dispossess the Creeks and Cherokees, who, relying on the treaties made with the United States, appealed in vain to congress and the supreme court. Failing to obtain redress, they yielded and agreed to remove beyond the Mississippi in pursuance of a plan for collecting all the Indians in one territory, to be theirs inviolably and for ever. Though treaties were signed in 1825, the removal was not completed till 1838. The Seminoles under Micanopy and Osceola refused to emigrate, and a war ensued in 1835 which lasted till 1842, and cost over \$15,000,000. The Sacs and Foxes under Black Hawk gave trouble in 1832. Greater trouble was given by the Sioux or Dakotas, who from time to time attacked frontier settlements and had to be reduced. The Comanches and Apaches have been almost constantly committing depredations, often joined by other tribes. The Oregon tribes have several times been at war with the whites. The establishment of the Indian territory in 1833, the removal of the Choctaws and Creeks, and the settlement of the Quapaws and other tribes there, were followed by the formation of other reservations, under state management in New York, and under the general government in Michigan, Wisconsin, Minnesota, Kansas, Nebraska, Wyoming, Montana, Idaho, Dakota, Colorado, New Mexico, Utah, Nevada, Arizona, California, Oregon, and Washington territory. The civil war was ruinous to the tribes in the Indian territory. Geographically in the south, the confederate government took possession of it, and was supported by many of the chiefs. Others attempted to take part with the United States government. The result was disastrous in loss of life and property. In 1869 a board of Indian commissioners was created to superintend the disbursement of appropriations, and inspect goods furnished to the Indians. The powers of this body have been from time to time increased, but some new measures were adopted which have not yet been tested by time, such as that of assigning certain districts exclusively to certain missionary bodies, and the consequent confounding of the duties of Indian agent and missionary. The following is the return of the Indian population on reservations in 1871:

Sioux in Nebraska, Montana, and Dakota.....	42,998
Choctaws, Indian territory.....	15,000
Cherokees, Indian territory.....	14,682
Gros Ventres, Assiniboins, Cheyennes, and Arapahoes, in Montana.....	13,900
Creeks, Indian territory.....	13,000
Utes in Nevada, Utah, and Colorado.....	12,720
Chippewas in Kansas, Minnesota, and Wisconsin.....	11,656
Chippewas and Ottawas in Michigan and Indian territory.....	8,706
Navajos in New Mexico.....	8,234
Pueblos in New Mexico.....	7,688
Shoshonees and Bannocks in Wyoming, Idaho, and Oregon.....	7,637
California tribes.....	7,033
Six Nations, Iroquois, in New York, &c.....	6,305
Kiowas, Comanches, and Apaches.....	5,372
Oregon tribes.....	5,365
Crows in Montana.....	5,100
Chickasaws in Indian territory.....	5,000
Pimas, Maricopas, Papagos, and Cocopas, in Arizona.....	4,031
Apaches in New Mexico.....	3,479
Arapahoes and Cheyennes in Indian territory.....	3,350
Dwamish, &c., in Washington territory.....	3,353
Osages in Indian territory.....	3,375
Colville, Spokanes, Okanagan, Washington territory.....	3,349
Nez Percés in Idaho.....	2,707
Yakamas in Washington territory.....	2,700
Pawnees in Nebraska.....	2,384
Seminoles in Indian territory.....	2,300
Pend d'Oreilles, Flatheads, and Kootenays, in Montana.....	1,900
Pottawattamies, in Indian territory and Kansas.....	1,736
Blackfeet, including Bloods and Piegans.....	1,560
Menomonees in Wisconsin.....	1,348
Nesqually, &c., in Washington territory.....	1,289
Wichitas, Caddoes, &c., in Indian territory.....	1,216
Omahas, Nebraska.....	954
Chehalis, Washington territory.....	900
Sklallams, Washington territory.....	825
Sacs and Foxes with Iowas.....	763
Mohaves, Arizona.....	725
Kansas, in Kansas.....	627
Makah, Washington territory.....	550
Otoes and Missourians in Nebraska.....	450
Spokanes and Cours d'Alene, in Idaho.....	310
Kickapoos, Kansas.....	246
Illinois and Miami, Indian territory.....	251
Quapaws, Indian territory.....	225
Stockbridges and Muncses, Wisconsin.....	220
Wyandots, Indian territory.....	169
Shawnees.....	73
Total.....	237,478

Besides the Indians thus on reservations, there are 60,000 in Alaska, and tribes not yet brought in, as the Apaches, Comanches, Lipans, and Kickapoos, with a few remnants of tribes in Maine, Georgia, &c. (2,000), and Florida (500), estimated at 53,000 more, making the total Indian population of the Union about 350,000, according to the estimate of the Indian department in 1871.—That the red race is steadily diminishing can scarcely be doubted. In 1829 the entire Indian population of the United States was estimated at 313,000; and though the annexation of Texas, New Mexico, and California brought in a large addition, the estimate of 400,000 made in 1850 was evidently too large. In 1855 Mr. Schoolcraft's estimate, with all the data of the Indian department, was 350,000. In 1871 the commissioner estimated them, including 60,000 in Alaska, as still 350,000, showing an actual decrease of 60,000 in 16 years. Yet some of the civilized tribes have held their own. The Cherokees in 1822 numbered 11,000; 1825, 15,000; 1871, 14,682. The Chippewas and Ottawas in 1822 were 18,977; 1825, 18,850; 1871, 19,732. The Iroquois in 1822, 4,000; 1825, 4,510; 1871, 4,958. The Chickasaws in 1822, 3,625; 1871, 5,000. The Creeks and Choctaws in that

period lost about one third, the Seminoles one half, the Sacs and Foxes seven eighths.—In the eye of the law the Indian originally held an anomalous position, neither citizen nor alien, and incapable of becoming a citizen. In some parts marriage between Indians and whites was severely punished. The disabilities have recently been removed, and Indians are enabled to leave their tribes or renounce the tribal system as a body and become citizens. Col. Ely S. Parker, a Seneca Indian, has even held the office of Indian commissioner. This step enables the more intelligent and industrious Indians to identify themselves with the white population, and induce others by their example to follow the same course. The Indian population of the British colonies is estimated at 150,000. That in Mexico and Central America is not easily ascertained, but form the major part of the people. South America, with some civilized and many wild tribes, has about 7,000,000 Indians.

AMERICAN INDIANS, Languages of the. The languages spoken by the natives received little attention in the English colonies; but in French, Spanish, and Portuguese America a more or less extended Indian literature grew up, with grammars and dictionaries of many of the languages. Charlevoix was perhaps the first to call attention to the languages as the surest mode of tracing the origin and affiliation of tribes. Hervas, availing himself of the labors of many members of the society of Jesus who had been driven from Spanish America, first in his catalogue of languages made a step toward a collection and comparison of the whole. Smith Barton made the first attempt in the United States to reduce the languages to system. Duponceau and Schoolcraft followed him. The Humboldts gave an impulse toward a philosophical treatment of the study, and Balbi in his *Atlas ethnographique* popularized the information acquired. At a later date Albert Gallatin performed an immense service by securing new, full, and harmonious vocabularies, and tracing many remote and overlooked affinities, so that his work has become the real basis for all subsequent labors as to the tribes of the United States. Turner devoted many years of philosophical and accurate investigation to the subject. In Europe Adelung philosophically arranged the general study, and Buschmann and others contributed to the investigations of particular families of languages. Orozco and Pimentel classified the languages of Mexico, Squier those of Central America and Peru, Brasseur de Bourbourg and the accurate Behrendt also elucidating those of Central America. Those who have labored on single dialects in Europe and America are too numerous to note. Ludewig became the bibliographer of the labors in this field in his "Literature of American Aboriginal Languages" (London, 1848).—The languages of America form a group apart, no one having been found that can take its place as a dialect

of any in any other quarter of the globe. They have features common to all, one being the predominance of the verb, by which the verb, subject, and object, direct and indirect, are often conjugated together as one word. In alphabetic power some, like the Iroquois, have no labials; the Mexican wants *b, d, f, g, r, s*, and the aspirate; the Choctaw has no *d* or *g* hard; the Otomi, no *l, r, or s*, but it has an emphatic *k* and *t*; the Quichua has a guttural *h*, emphatic *p, t*, and *s*, and aspirated *p, t*, and *k*. The Otomi, Athabascan, and many of the northwestern tribes have singularly confused, peculiar, or clucking sounds, often impossible to denote. Almost all known American languages have comparatively limited vocabularies, and lack abstract or general terms. Many have, for instance, no word for brother in general, but separate words for elder and younger brother, differing again according as spoken by another brother or a sister. So there will be no general word for "to fish," but distinct words for fishing with a net, spearing, spearing through the ice, fire-fishing, &c. Some have two sets of numerals, one for man and a few objects deemed of highest importance, the other for everything else; and some have even a third set of numerals for money.—We can give only a general view of the American languages. I. **NORTH AMERICAN.** The general name of Esquimaux (raw-fish-eaters) comprehends all the languages of Greenland and of the northern countries, from the coast of Labrador to Behring strait and the peninsula of Alaska, including also that of the settled Teluktelis of Siberia. They consist of two groups: the eastern or Esquimaux proper, with three dialects in Greenland, Labrador, and on the N. and W. shores of Hudson bay; the western, with the idioms of the Telugateles, Aleutians, and both American and Asiatic Teluktelis, which differ more one from another than those of the eastern group. The dialect on Winter or Melville island lacks the sounds *f, g, r, z*. As in almost all American languages, the pronunciation is, so to speak, pectoral, and the consonants are indistinct. The Esquimaux have words for all shades of meaning in which an object is taken, according to its age, sex, and other categories. Many suffixes and few postpositions denote the accidents of declension, comparison, and conjugation. Examples of words: *kernertok*, (who is) black; *aglegiartorasuarpok*, he quickly goes away to write. Numeration proceeds by 20. For the Hudson bay dialect, see the works of Dobbs, I. Long, and Parry; for that of Kotzebue sound, see Beechey; for that of the Teluktelis, see Kosheloff and Khromensko.—The language of the Karalits (Greenlanders) lacks *d, f, h, z*, and, as initials, *b, g, l, c*; abounds in *t, k, r*; and accumulates hard syllables, although the people have a fine ear and musical taste. There are three dialects, viz.: the Kamuk of Upernavik; that of the isle of Disco, the purest; and the southern, of Julianeshaab. Numerals beyond 5 are compounded; 20 is desig-

nated by the words "hands and feet," &c. For grammars of their tongue, see Thorhallesen (1776), and P. Egede (1760), who also made a dictionary, as well as O. Fabricius (1791-1804).—On the northwest of the American continent, south of the Esquimaux, is the family of the Koloshes, found about Alaska. South of the Esquimaux, on the east and south of Hudson bay, and running west in a narrow strip along the Saskatchewan to the Rocky mountains, and extending from the Red and Mississippi east to the Atlantic as far down as lat. 36°, was the extensive Algonquin family. It occupied the whole of this vast territory, to the exclusion of all other races except the Winnebagoes on Lake Michigan, who belonged to the Dakota family, and the Huron Iroquois family, who, surrounded by Algonquins, extended from Lake Huron to North Carolina. The Algonquin family, taking its name from tribes on the Ottawa river, Canada, comprised, above the St. Lawrence and the lakes, the Nasquapees, Montagnais, Algonquins, Ottawas, and Kilitinons or Crees; on the Atlantic coast, the Micmacs, Abenakis, Sokokis, Massachusetts, Narragansetts, Molegans, Delawares, and Virginian tribes; in the west, the Chippewas, Menomonees, Pottawattamies, Miamis, Illinois, Sacs and Foxes, Blackfeet, &c.; at the south, the Shawnees. Many of these dialects have been studied thoroughly, and many books and even papers have been printed in them. For their study we have Maillard's Micmac grammar (New York, 1864), Kåle's Abenaki dictionary (Cambridge, 1833), Eliot's Massachusetts grammar (Cambridge, 1666; Boston, 1822), Roger Williams's Narragansett (1643), Edwards's Mohegan grammar (1788), Le Boulanger's Illinois grammar and dictionary (MS.), Baraga's Chippewa grammar and dictionary (1851-3), Belcourt's Chippewa grammar (1839), House's Cree grammar (1844), Cuoq's Algonquin grammar (1866), Zeisberger's Lenni Lenape or Delaware grammar (1827). As the Algonquin was the language of the tribes on the seacoast where the English colonies were planted, it gave several words to the settlers, as wigwam, squaw, wampum, tomahawk, sachem, &c. In the Algonquin dialects there is no article, and no gender, words being used when necessary to designate the male and female of animals and birds. The only division is into what has been called noble and ignoble, or by some animate and inanimate. The Delaware made trees noble, grass ignoble. Possession is designated by a form like the English Peter his book—*Pien o masinaigan*. It has two numbers, though some from the double pronoun *we* make a dual also. Nouns receive by suffixes modifications that some term cases; but nouns like verbs undergo a kind of conjugation by the prefixing of possessive pronouns. Thus in Delaware: *ooch*, father; *nooch*, my father; *kooch*, thy father; *noochenana*, our fathers; *koochura*, your father; *koochewica*, your fathers. Algonquin: *ni micomis*, my grandfather; *ki micomis*, thy

grandfather; *omicomisan*, his grandfather; *ni* (or *ki*) *micomisanan*, our grandfather; *ki micomisica*, your grandfather; *omicomisican*, their grandfather. Verbs take a multiplicity of forms, not only positive, negative, reflexive, and reciprocal, but animate and inanimate. Thus in Algonquin: *ni sakiha*, I love him (animate); *ni sakiton*, I love it (inanimate); *ki sakiha*, thou lovest him; *osakihan*, he loves him; but *ki sakih*, thou lovest me; *ki sakihimin*, thou lovest us; *ki sakihim*, you love me; *ki sakihin*, I love thee; *ki sakihinimin*, we love thee. In all these there are two forms of *we*: he and I, *ni*; thou and I (with or without others), *ki*. In Delaware: *ndahoala*, I love; *kdahoala*, thou; *wdahoala*, he; *ndahoolaneen*, we; *kdahoolahumo*, you; *wdahoolawek*, they; *ndahootell*, I love thee; *klahooli*, thou lovest me. The passive in Algonquin is *ni sakihigo*, I am loved; in Delaware, *ndahoolgussi*. I am loved by him (Alg.), *ni sakihik*.—The Huron-Iroquois family comprised, in Upper Canada, the Hurons or Wyandots, Tionontates, Attiwandaronk; the Iroquois, Hodososaunee, or Five Nations in New York; the Minquas, Andastes, or Susquehannans in Pennsylvania; the Nottoways, Meherin, &c., in Virginia; the Tuscaroras in Carolina, and subsequently in New York. The dialects generally lack the labials. Of those that have been most studied is the Mohawk, into which the Book of Common Prayer and portions of the Bible have been translated, as well as Roman Catholic manuals of prayer, catechisms, &c. The radical words of this dialect, by Bruyas, were published at New York in 1863; a short grammar by Cuoq, Montreal, 1866. Of the Onondaga, there is a dictionary published in 1860; of the Seneca, a spelling book and some minor works. In Iroquois dialects the verbs have two distinctly marked paradigms, each containing five regular conjugations. In the paradigm *k* there are 15 persons, I, thou, he, she, and an indefinite pronoun like the French *on*; thou and I, he and I, you two, they two masculine, they two feminine, making five dual forms; and for the plural, you and we, they and we, you, they masculine, they feminine. In all the verbal relations pronouns in their separate form are replaced by affixes which modify the initials of the persons. M. Cuoq adds to the three numbers another, the indeterminate. Every noun is or may become a verb. There are no articles, no prepositions, and few adjectives, adverbs, or conjunctions. Nouns have no cases, and no gender proper, the only distinction being that of two classes, one comprising God, the angels, and males of the human race, the rest all other creatures animate or inanimate. The verb assumes reflexive, reciprocal, and passive forms by inserting syllables. Thus: *kenowices*, I love; *kutatenowices*, I love myself; *tattatatenowices*, we love one another. The pronoun object enters into the verb, as *rinowices*, I love him. Verbs of the paradigm *w* have four

persons less than those in *k*; but strangely, the perfect in verbs of *k*, and all their derivatives, are conjugated under the paradigm *w*. Indicative present: *keonowes*, I love; *senonowes*, thou lovest; *ranowes*, he loves; *kanowes*, she loves; *ienowes*, some one loves. Perfect: *wakonowechon*, I have loved; *sanowechon*, thou; *ronowechon*, he; *wonowechon*, she; *iakonowechon*, some one. Present: *wakeriwai-en*, I am busy; *saricai-en*, thou; *roricai-en*, he; *ioricai-en*, she; *iakorwicai-en*, some one. —West of Hudson bay, above the Churehill river, were the northern part of the Athabascan family, some tribes of which dwelt on the shores of the Pacific, and the main body extending south to the Dakotas, while the southern part of the family occupied the frontier between the United States and Mexico. The tribes are strangely different in character, the northern being timid, the southern fierce and bold. The chief tribes at the north were the Chipewyans, Tabeulli or Carriers, Dog Rib Indians, Sus-sees, Tlatskanai, Umpquas, Kwallioqua, Kenai, &c. Of the southern, the most conspicuous tribes are the Apaches, Navajoes, and Lipans. Of this family we have little to show the grammar or affinities. —South of the Athabascan family, and between the Mississippi and the Rocky mountains, were the Dakota family, extending as far south as the Arkansas river, and having one tribe on Lake Michigan, the Ochungaras, called by the Algonquins Winnebagoes. The Dakota family includes the Assiniboins, the Dakotas or Sioux, Iowas, Omahas, Puncas, Missouris, Osages, Kansas, Ottoes, Arkansas, Mandans, Minnetares, and Crows. In Dakota there are separate and incorporated pronouns. There is a dual first person, we (thou and I), but there is no incorporated pronoun for the third person in either number, so that the third person singular is the simplest form of the verb. Verbs have an indicative, imperative, and infinitive, and two tenses, an indefinite and a future. A few examples will suffice: *Kashka*, he binds; *yakashka*, thou bindest; *wakashka*, I bind; *unkashka*, we two bind; *kashkapi*, they bind; *yakashkapi*, ye bind; *unkashkapi*, we bind. In other cases the pronouns are introduced, as *manon*, he steals; *mayanon*, thou stealst. There are some irregular forms, as *hiyu*, he comes; *hidu*, thou comest; *hibu*, I come. The pronoun object enters into the verb: *kashka*, he binds him, her, it; *nicashka*, he binds thee; *makashka*, he binds me. Case is shown by position, possession by the possessive at the end: *wichash-tayatapí tipí tuwa*, chief house his, *i. e.*, the chief's house. The plural is formed by adding *pi* to nouns and verbs. There is a grammar and dictionary of the Dakota by the Rev. S. R. Rigg (Washington, 1852), and an Iowa grammar by Irvin and Hamilton (1848). —Adjoining this family were the Pawnees, embracing the Pawnees, Rickarees, Huccoes, and Wichitas, roving bands long known, but as to whose language our knowledge is con-

fined to vocabularies. —Next to the Athabascan family on the Pacific coast are the Kitunahas or Flatbows, and the large family of the Selish, embracing the Shushwaps or Átnahs, Flatheads, Skitsuish or Cœurs d'Alène, Piskwans, Clallam, Lummi, Sinniam, Songhus, and some other tribes. Their language has been made known by the *Grammatica Linguae Selicæ*, a Selish or Flathead grammar, by Mengarini (New York, 1861). The Selish lacks *b*, *d*, *j*, *r*, and *v*; *g* is guttural like the Spanish *j*; *ck* is very hard; it has a peculiar *h*, pronounced with the tongue at the palate. Nouns have no cases, but form plurals by doubling the roots, as *skoi*, mother, *skoiko*, mothers, and in several other modes. It has absolute pronouns and copulative pronouns, the latter used in connection with verbs. The verb *to be* exists and enters into the conjugation of indeterminate verbs. The determinate active verb is thus conjugated: *Ies kól-m*, I do (something definite); *as kól-m*, thou dost; *ès kól m*, he does; *kaes kól-m*, we do; *ès kól m-p*, you do; *es koolm*, they do. Perfect: *kol n*, I did; *kól nt-p*, thou didst. The relative forms vary thus: *ku iès asgam*, I see thee; *ko as asgam*, thou seest me; *ies asgam*, I see him; *ko es asgam*, he sees me. —The Sahaptin family, bounded on the north by the Selish, comprise the Sahaptin or Nez Percés and the Wallawallas, running east to the Rocky mountains and south to the Shoshonees. The Wallawallas comprise several tribes, the Yakamas, Palus, Klikatats, and Tairtla. The study of their language is aided by Pandosy's "Grammar and Dictionary of the Yakama Language" (New York, 1862). The language is remarkable for the multiplicity of its pronouns, and for a twofold conjugation of its verbs, one with the tense form unchanged for the persons preceded by the pronoun, the other with the tense form modified by a pronominal suffix, except in the third person, where it is affixed. —Below them are the Waitapu family, comprising the Cayuse and Molele. Beyond this family were the once numerous Chinook family, embracing a number of tribes from the mouth of the Columbia to the Grand Dalles. They have disappeared with fearful rapidity, and the fullest vocabulary is that by George Gibbs (New York, 1863). Below and above these on the coast were scattered tribes and families, whose relation to others will never perhaps be now known from the utter want of material of an extended character. —The Shoshonees, another important family, comprise the East and West Shoshonees, on the head waters of the Missouri and Columbia; the Bannacks, on Snake river; the Comanches, from the head waters of the Brazos to those of the Arkansas and Missouri; the Yutes and Pa Utes, in Utah territory; the Kiowas, in Texas; and several tribes in California, the Kizh of San Gabriel, the Netela of San Juan Capistrano, the Kechi of San Luis Rey, the Cahuillos, and perhaps the Moquis. The other California tribes belonged to several distinct families. Arroyo's grammar

and vocabulary of the Mutsun (New York, 1861-2) affords material for studying that language, spoken at San Juan Bautista, Monterey county, at La Soledad on Salinas river, and by the Kumisens or Achastlians at San Carlos. A vocabulary with some grammatical notes on the language spoken at the mission of San Antonio shows the absence of pronouns in the third person and great simplicity of forms. The languages of the Pueblo Indians of New Mexico form a class by themselves.—South of the Algonquins were the family of the Catawbas and Wacoco in the Carolinas; and the very extensive family of the Cherokees, embracing the Ottawa and Ayrate. Their language, which has analogies with the Iroquois dialects, is remarkable as the only one in which the natives have adopted an alphabet. It was invented by Sequoyah or George Guess, a half-breed, in 1826. His scheme consists of 85 characters, including six vowels, *a, e, i, o, u*, and the French nasal *un*; and nine simple and three combined initial consonants, *g, h, l, m, n, kv, s, d, dl, ts, w, y*, to which the vowels are attached. The sounds *k* and *g*, *t* and *d* occur almost promiscuously, and *dl* or *tl* are sometimes written *kl*. As in most languages, there are two forms of *we*, viz., the prefix *in* for I and thou, and *ast* for I and he; as *inaluniha*, I and thou bind it; *astaluniha*, I and he bind it. Plurality is denoted by the prefix *t* or *te*, as *tetsiguacati*, I see things. Continuative action is indicated by the suffixes *sa* and *i*, as *tsikeyusa*, I love him unceasingly. The perfect tense is of two sorts, one used when the narrator was present at the action, the other when he was absent; thus: *uhlun*, he killed him (in my presence), and *uhlëi* (in my absence). The transitions of the verb are either, 1, as animate, or 2, as inanimate; thus: 1, *galuniha*, I bind it (an animal or tree); *haluniha*, second person; *kahluniha*, third person; dual: *inabuniha*, I and thou bind it; *astaluniha*, I and he bind it; *istaluniha*, ye two bind it; plural, *italuniha*, we bind it; 2, *galunihawî*, I bind habitually, or am in the habit of binding, &c. Objects are frequently expressed merely by changes of the verb, as *kutuwo*, I am washing myself; *kulestula*, I am washing my head; *tsestula*, I am washing another person's head, &c., through 13 different forms. All words of relations between parts of speech are postpositions. Parts of the Bible and books of elementary instruction and newspapers constitute the Cherokee literature.—Below the Cherokees were the Muskokees or Creeks, the Choctaws and Chickasaws, the last two speaking the same language, the first a language bearing strong analogies to it. The Spaniards cultivated the Timuquan, a Choctaw dialect, and a grammar, catechism, &c., were printed in it as early as 1613-27. The Choctaw proper has been thoroughly investigated in our time by the late Rev. Cyrus Byington, whose "Definer" (1852) and "Choctaw Grammar" (Philadelphia, 1870) give very satisfactory means of study. The language is

remarkable for its multitudinous particles with nice shades of meaning. It has the usual separable and inseparable pronouns, and the double *we*. Like the Dakota, Mexican, San Antonio, and some others, the third person singular of the present of the verb has no pronoun, and gives the simplest form of the verb. The inseparable pronoun for the first person is a suffix; for the second, an affix: *Takhih*, he, she, or it ties, or they tie him, her, it, or them; *ishtakhih*, thou tiest him, &c.; *takchilih*, I tie, &c. Among the peculiarities is a pronoun used among those related by marriage. The Muskokee language is divided into the Muskokee proper or main Creek and the Hitchitee. The only grammar is that by Buckner (New York, 1860). The verb in its modifications differs from the Choctaw. *Issetv* (*v* representing an obscure sound), to take; *esais*, I take it; *esichkis*, thou takest it; *esis*, he takes it, &c. Neither Creek nor Choctaw has the sound of *a* in fate or the letters *d, g, j, r, v*, or *z*.—The Natchez, on the Mississippi, had a peculiar language which has some analogy with the Maya. Of the other Louisiana tribes our data are limited; the Chetimachas and Attakapas had languages that enter into no known group. Those of Texas were studied by the Spanish missionaries, and works were printed in them, but their affiliations are not known.—The languages of Mexico have been classified by recent scholars, Orozco and Pimentel. The first family is the Mexican, including the Nahoas, the Pipil in Central America, the Zacateco, the Chimarra and Concho in Chihuahua, the Ahnaluco in Tabasco, the Jalisco, the Acaxee, the Sabaibo in Durango, the Xixime and Tebaca in Sinaloa. It extended from the Gila and Rio del Norte to Guatemala. As the language of one of the most civilized races in the new world, it was studied by the Spaniards and cultivated, a professorship being founded in the university of Mexico. A number of grammars have appeared, by Olmoz (1555), Molina (1571), Rincon (1595), Guzman (1647), Vetancurt (1673), Avila (1717), Zenteno (1753), Aldama (1754), and Sandoval (1810); and the dictionary of Molina (1571) is very full. A general view of the language by Albert Gallatin will be found in the "Transactions of the American Ethnological Society," vol. i. The Mexican language lacks the sounds *b, d, g, r, j* (Spanish), *ll* (Span.), and *gn* (Italian), but it abounds in *t, z, ch* (Span.), *tz*, and in the syllables *tla, tli, atl, itl*; *x* is pronounced with a peculiar guttural sound. The tone generally strikes the penultimate of the polysyllabic expressions, in which the particles *ca* and *ti* predominate. Gender is distinguished in animals by the prefix *okich*, male, *ehina*, female. There is only one variation for case, *é* being added for a vocative by men, but only an accent on the last syllable by women. As a general thing, inanimate things have no different form for singular or plural; some have, as *milli*, sowed ground, plural *millin*. Of plurals of animate nouns

these are samples: *Icheatl*, a sheep, *icheame*, sheep; *coutl*, a snake, *cocou*, snakes; *tatl*, father, *tatin*, fathers. All nouns may unite with four particles: *tzin* or *tzintli*, signifying respect; *ton* or *tonth*, depreciating; *pol*, signifying excess; *pil*, diminutive implying affection: as *icheapil*, a lamb (dear little sheep). Possessive affixes are *no*, *ma*, *i*, *to*, *anmô*, *in*. *Culli*, house; *nocal*, my house; *nomill*, my sowed ground; *ical*, his house; *icritl*, foot; *nocxi*, my foot; *teotl*, God; *notcouh*, my God; dropping a termination, and sometimes substituting another. The inseparable pronouns for conjugations are: 1st person singular, *ni*; 2d, *ti*; plural, 1st, *tî* (strongly accented); 2d, *an*, *am*. *Niemi*, I live or walk; *tiemi*, thou; *nomi*, he; *tinemi*, we; *anemi*, you; *nemi*, they. In the imperative, *tî* and *an*, of the 2d person, change to *xi*, and *ma* is prefixed to all persons. *Ma* or *maucela* is prefixed for the optative. Participles are wanting. It has the usual transitions. *Ni tlazotla*, I love; *nino tlazotla*, I love myself; *nî pîs*, I guard, *e. g.*, John; *nî tlapia*, I guard him; *nî tepia*, I guard it, &c. The Mexican has given us two common words, tomato (*tomatl*, waterberry) and ocelot (*ocelotl*).—The next family is the Otomi or Hiahiu (pronounced Hianghiung), a monosyllabic language resembling the Chinese. Its dialect is the Mazahui. The Otomi is spoken in Mexico, Michoacan, San Luis Potosi, Querétaro, most of Guanajuato, and parts of Puebla and Vera Cruz. Its grammar is peculiar from the fact that the verb remains unchanged, the pronoun being conjugated. It has many words of the same letters distinguished by the intonation. It lacks *f*, *l*, *r*, and *s*, and abounds in guttural and nasal sounds; has a peculiar *c* (*cc=qq*), pronounced with the root of the tongue and palate; a dental *t* (*tt*); and a variety of vowel sounds quite unusual, *a* having four, *e* four, *i* three, *u* four, and *z* has three sounds. Distinctions are made by prefixing *na*, *ma*, *xo*: *nho* or *manho*, good; *xanho*, a good thing; *mâli*, to love; *nalmâli*, love.—The Huasteco-Maya-Quiche is a remarkable language, extending over a very wide range, of which the Huasteco seems a northern offshoot. It is spoken with the Totonac in Puebla, Vera Cruz, and San Luis Potosi. The Maya proper and its dialects, the Lacandon, Peten, Caribe, Chafubal, and Punetune, are spoken in Yucatan, Chiapas, and Tabasco; while its kindred tongue, the Chontal, prevails in Tabasco, Oajaca, Guerrero, and Guatemala; the Quiche and Mam in Chiapas and Guatemala: the Tzendal and Tzotzil in Chiapas; the Col in Chiapas and Guatemala, with the Totzlem. Gage made the Poconcho, a dialect of the Mam, known to English readers two centuries ago. In our time extensive studies have been made as to it by Squier, Behrendt, and Brasseur de Bourbourg. It resembles the Otomi in monosyllabism and tones; it has six gutturals which are extremely rough; it lacks the sounds of *d*, *f*, *g*, *r*, *s*; its words are not inflected. The plural is formed

by *oh*, the comparative by *il*; thus: *che-oh*, woods; *tib-il*, better. There are four conjugations. The language abounds in elisions. As spoken in a district of Valladolid, it is praised for elegance and conciseness. By many the Chontal is supposed to have been the language of Cuba and Hayti, the tongue which has given us the earliest words that were adopted into European languages, tobacco, canoe, &c.—The Mixteca-Zapoteca language has several dialects: the Chocho in Puebla, Oajaca, and Guerrero; the Yope in the two latter states; the Popoloco or Teca in Michoacan, Jalisco, and Guatemala; the Amuecho in Guerrero; the Zapoteca and Chiateco in Oajaca. A Mixteca grammar by Antonio de los Reyes and a vocabulary by Alvarado were printed at Mexico in 1593; a grammar of the Zapoteca by Cordova was printed there in 1564, and a vocabulary by the same author in 1578. The Matlaltzinea or Pirinda is spoken in Michoacan; the Ocuilteca in the state of Mexico seems related to it. Of this grammars were written, but none have been published. The Tarasco prevails in Michoacan, Guerrero, Guanajuato, and Jalisco. In this language *f* and *l* are wanting; and *b*, *d*, *g*, *i*, and *r* never begin a word. Nouns are divided into rational, irrational, and inanimate. There are absolute and inseparable pronouns. In conjugating the inseparables are suffixed: *Pe*, to carry; *pa haac*, I carry; *panghaac*, I am carried; *panstahuca*, I am always carrying; *pacata*, that which is carried, a burthen. There is a Tarasca grammar by Baselenque (Mexico, 1714), of which a sketch is given in the "Transactions of the American Ethnological Society," vol. i., pp. 245, &c.—The Opatá-Tarahumara-Pima family embraced a number of dialects spoken by tribes in Sonora, California, and Arizona; the Opatá and Eudeve in Sonora; the Jova in Sonora and Chihuahua; the Pima with its dialects, the Papago, Sobaipuris, Yuma, and Calueneche, in Sonora; the Tarahumara in Chihuahua, with dialects in Durango and Sonora; and the kindred Tepehuan in Durango, Jalisco, Chihuahua, Coahuila, and Sinaloa. This family also includes the Cahita, Cora, and Colotlan. A grammar of the Pima or Nevome (New York, 1862) shows it to lack the sound of *a* in fate, *f*, *l*, and *z*; *b* and *p*, *d* and *t*, *e* and *g* are easily confounded; contractions are numerous. There is but one conjugation of the verbs, and the verbal form in each remains the same in each tense, the pronoun and prefixes varying with the persons. The active verb is simple compared to the passive: *ani haquiariida*, I count; *ani haquiariideada*, I counted; *nî vusi rointat'am'igui*, I was assisted. Verbs of possession are made from nouns: *hunu*, maize; *hunuqa*, to have maize. See too "A Sketch of the Heve (Eudeve) Language," by Buckingham Smith (New York, 1861).—The Seris, including the Upanguaima and Guaima, were in Sonora. In Lower California were two families; the Guafurn, with five dialects, the Cora, Uchita, Concho, and

Laymon; and the Cochimi, with three, North Cochimi, Edu, and Didu. Of the Guaicuru our best notice is in Begert's *Nachrichten* (Mannheim, 1772), of which Rau has given a translation.—In Central America, besides the Maya and Mexican already noticed, there were families which Squier supposes affiliated with the Guaranis and Caribs. For the study of these we have Cotheal and Henderson's "Grammatical Sketch of the Mosquito" (New York, 1846), Scherzer on the Valientes and Talamancos, Squier's vocabularies, and his monograph of authors on the languages of Central America (London, 1861). II. SOUTH AMERICAN. The Caribs (whose vernacular name was Calina or Galibi) once dwelt on the shores of Colombia, in Guiana, and on the Lesser Antilles. They speak about 30 dialects, which are very harmonious, but of a weak utterance, so that *l* and *r*, *b* and *p*, *g* and *k* are almost alike. Nearly all words end in vowels. Conjunctions conclude the sentence; animate and inanimate things have different forms of expression. Terminations of cases: dative *va*, accusative *pona*, ablative *tu*. Persons: masc. *au*, *inara*, fem. *nucuya*, *niuro*, I; *nana*, we; *amoro*, *iburra*, *ameule*, thou; *hocoya*, you; *likia*, he; *moscan*, they. Possessives: prefix *e*, my; *a*, thy; suffix *o*, his. Verbal pronouns: prefix *s*, 1st person; *m*, 2d; *n*, 3d; plural, *nunan*, &c. Of the principal Caribbean dialects, the Chaymas is spoken in Cumaná. The Tamanaca has more verbs obtained by means of prefixes than perhaps any other language; it lacks *f*, *s*, and *g*, has six conjugations, many tenses (a preterite of yesterday, another of two weeks ago, a third of six months and more ago), and forms for near, others for distant objects; the auxiliary of the passive is *uociri*, to be; brother and sister are distinguished as to age, as in Magyar and other Uralic tongues. The Arrawak, on the banks of the Berbice and Surinam, has many remarkable peculiarities, such as the formation of the passive voice by changing the final *n* of the infinitive active into *hun*, and many prefixes and suffixes. Caribbean grammars were published by Fathers Tauste, Ruiz Blanco, R. R. Breton, and Gilj, and dictionaries by the first and last named (1665-'7), and an anonymous one (Paris, 1763). Some writers represent the Caribbean language as a branch of the Guaraní, which they divide into the southern or Guaraní proper, the middle or Tupi of Brazil, from the island of Santa Catarina to the mouths of the Amazon, and the northern or Caribbean.—The following seven languages are worth notice, viz.: 1. That of the Mozeas (Muscas), who before the advent of Europeans inhabited the table land of Bogotá, and who in consequence of a culture higher than that of their neighbors extended their idiom among them. It once prevailed in the city of Bogotá, but is now extinct. It counted by 20, had a negative conjugation, and many excellent peculiarities; it lacked *l* and *z*, and had an indistinct *l*. 2. Of

the Saypures, on the upper Orinoco. 3. Of the Salivis, between the Meta and Guaviare, affluents of the Orinoco, and in the Venezuelan province of Casanare; full of nasal sounds. 4. Of the Ottomacs, between the Apure and Sinarucu, spoken with the utmost rapidity. 5. Of the Yururas, between the Meta and the Casanare; it lacks *s*, abounds in the Spanish aspirate *j*, and uses the substantive verb as auxiliary of all others. 6. Of the Betois, on the Casanare, without *p*. 7. Of the Mainas, in the province of that name, differing from its neighbors. In the eastern parts of Colombia there are Caribbean dialects. Grammars have been prepared by Fathers Anisson, De Tauste, and De Lugo, and a vocabulary by De Tauste (1680).—The Andi-Peruvian family of nations is divided into four classes: 1. The Quichuas (pronounced with a faucal croaking sound, hence also written Quiclihuas) or Incas were more widely spread at the time of the European invasion than they are now. They differ from the other indigenous races of South America, resembling more the Mexicans, and being of a dark olive complexion. The language of the Incas, however, was not intelligible to their subjects, and Fr. Lacroix supposes that it was a sort of hieratic jargon, unknown to the profane. The Puquini about Paz and Lima obstinately conceal their idiom from foreigners. The language of the Quichuas was extended, by the agency of the Incas, over their whole empire; so that it was known to all officers and educated persons from Quito as far as Chili and the kingdom of Tumac, and, sporadically, as far as the banks of the Plata. It consists of five dialects: *a*, Cuzuecano, one of the most cultivated idioms of South America, spoken also by the creoles of Lima and by others; *b*, Quitña, the hardest and most corrupt; *c*, Lamano of Truxillo; *d*, Chinchaisuyo of Lima; *e*, Calchaqui of Tucuman. The Quichua sounds very harsh and explosive; it lacks *b*, *d*, *f*, *g*, *j*, *r*, *v*, *x*, and *z*. It has cases and prepositions. The plural is generally formed by adding *cuna*. It has two forms of *we*. *Munaní*, I love; *munanquí*, thou; *munan*, he; *munanchie* and *munaycu*, we; *munanquichie*, ye; *munanen*, they; *munac*, lover; *munnay*, love; *munasca*, the person or thing loved. It counts by tens up to hundreds of thousands; and has a very rich and perfectly regular conjugation, even of the substantive verb. Its phraseology is simple, and the verb concludes the sentence. It was used for writing even by the Incas, and the Limans prided themselves on their speaking it purely. There are grammars by Domingo de S. Tomas (1560), D. de Torres Rubio (1603), D. G. Holguin (1608), and many others; and in English, Markham's "Contributions toward a Quichua Grammar and Dictionary" (1864). 2. The Aymaras, probably descended from the high plains about Lake Titicaca (from the bosom of which Manco-Capac, the founder of the inca dynasty, was said to have risen), are almost surrounded by the Qui-

chuas, but differ from them in manners and language. This, though it has many harsh sounds, words, and grammatical forms, is spoken by the descendants of Europeans at La Paz, and by about 400,000 aborigines. It is rich in many modified expressions (having for instance 12 homonyms of the verb to carry), abounds in postpositions, and has several dialects. There are grammars by L. Bertonio (Rome, 1613) and D. de Torres Rubio (Lima, 1616). 3. The Atacamas, numbering about 8,000, on the W. slope of the Andes. 4. The Changos, about 1,000, on the Pacific.—On the E. declivity of the Andes, in Bolivia, the Antisian family (so called from the eastern of the three Cordillera ranges, and from which the word Andes is applied to all the ranges) contains five tribes with their own tongues, viz.: the Yuracares (*yurac*, white, and *carí*, men), Moeetenes (Chunchos), Tacanas, Maropas, and Apolistas; about 15,000 in all. (Tschudi, *Antigüedades Peruanas*, Vienna, 1852.) N. W. of Bolivia, on the Ucayali, are the Panos, who used a sort of hieroglyphics, and the Carapuchos, who seem to bark in speaking. On the pampas of La Plata, drained by the Paraná and both Salados, there are about 40 tribes, especially in the forests of Chaco, of which we mention the most prominent. The Abipones, the centaurs of South America, seem to sing their long words; they have a peculiar sound, half *r* and half *g* (like the Arabic *ghain*), and count in their language only as far as three. The Mbayas (Guaycurus), on the Paraguay, also great horsemen, had an ancient idiom, and speak now the Enacagas, without nasals or gutturals; they have also a woman language (man, for instance, is called *hutege* by men, but *aytina* by women) and castes, and are called *Lenguas* by the Spaniards. The Moxos, about 13,000, in Bolivia and the Brazilian province of Matto Grosso, have a mild harmonious tongue, many modified forms of verbs, and very few numerals. There is a grammar and vocabulary by P. Marban (Lima, 1701). The Chiquitos, about 15,000, in S. E. Bolivia, near the Argentine Gran Chaco, have many nasal and guttural sounds, the French *u*, and an idiom for females, as well as a language of etiquette used in addressing God and superiors.—In the vast regions E. of the river Paraguay, and of a line from its sources to the mouth of the Orinoco, thence bounded by the shores of the Atlantic and on the S. by the Plata, there is, so to speak, an archipelago of tongues in the ocean of the Guarani family. In Brazil alone Teixeira counted 150 and Spix and Martius 300 tribes, with as many languages; but, as their affinities cannot be determined clearly, owing to the paucity of their consonant elements, it is impossible to know which of them are languages and which are dialects, or merely local idioms. Heras reports 51 languages as different from the Tupi, and 16 as akin to it. This Tupi is one of the three great branches into which the language of the Guarani is divided, viz.: 1. Eastern

Guarani (the *lingua geral*, general language of Brazil), which lacks *f*, *l*, *s*, and *r*, but has German *ch*, English *j*, French *u* (written *y*) and nasals, Spanish *ñ* and *ll*; also *mb*, *nb*, *nd*, *uy*. Cases: *aba*, homo; *abaupe*, homini; *abaki*, homine. There is no plural flexion. The comparative is formed by the suffix *ete*. Numerals do not go beyond 4, 5 being expressed by the word hand (*ambo*), 10 by two hands (*opacumbo*), and higher numbers in Spanish. Pronouns: *yac*, I, my; *nde*, thou, thy; *ae*, he; *y*, his; *oro*, we (I and he); *yande*, we (I and you); *pee*, you, *pe*, your. Verbs: *a-juca*, occido; *ere-juca*, occidis; *o-juca*, occidit, &c. Tenses are indicated by adverbs; voices and many kinds of verbs by intercalating particles. There is no substantive verb. Examples of phrases: *Co nanga xe reminbota* (Lat. *hec omnino mihi voluntas*), I wish it; *Ne marangatu (mihí bonitus)*, I am good; *Ori rub ybaqyqe tec-oar, imo-ete-pyram nde vera*, Our Father heaven-in being, hallowed-be thy name. There are grammars by Anehieta (Coimbra, 1595) and Figueira (Lisbon, 1687), a dictionary by the latter author, and a recent one by Dias (Leipsic, 1858). 2. Southern Guarani (Guarani proper), on the rivers Paraná, Paraguay, and Uruguay; spoken by many tribes. See a *Vocabulario* in Franca's *Chrestomathia Brazilica* (Leipsic, 1859). 3. Western Guarani, spoken by the Chiriguani (lat. 18° to 22° S.) on the Pilcomayo, the Guarayí in the missions of the Chiquitos, the Cirionos near Santa Cruz, and in 160 villages between the Chaco and Mapayo streams, in its purity. That dialect of the Tupi once prevailed over many districts is evident from the names of several tribes, such as the Tupinambas, Tupiniquins, Tapiguas, Tummimiri, &c.; so that it became the most extended native idiom in South America, and was adopted by the Europeans, as well as by many heterogeneous tribes, as the medium of communication. Its analogy with the other branches of the same family and with the Caribbean aided its extension. Here also the style of female speech differs in some particulars from that of men. The Omaguas, formerly a most powerful association of tribes, were the Phenicians of the Amazon, Japura, &c., being spread inland as far as the Rio Napo, on the affluents of the Orinoco, in Venezuela, to the S. in Solimoes, on the Pará, &c. Their language differs from all others in South America. It is monosyllabic, has nasal and guttural sounds, no gender, and a very simple conjugation. The same word has many significations, according to its tone; reciprocal verbs are formed by the suffix *ca*, and active verbs from nouns by *ta*. It points to the Otomi as well as to trans-Gangetic languages. Between the Madeira and the Tapajos the Mundurucus and Tocantins speak a tongue akin to the preceding. Other tribes on the Amazon have idioms which are related to either the Guarani or the Omagua. There are grammars of the Guarani by A. Ruiz de Montoya (Madrid, 1639), and P. Restivo, from Bandini,

(1724). Montoya also published a vocabulary. — Between the rivers Doce and Pardo, and between the Atlantic and the province of Minas Geraes, we find the Botocudos, who have a language of their own, with many nasal and other peculiar sounds, although scarcely any gutturals; they use a great many vowels, but confound many articulations, as *t* and *d*, and *l*, *n*, and *r*, together; for instance, *Turu*, or *Tahu*, God. Most of their words are monosyllabic. They have many onomatopœias and various figurative expressions, and they double many words; thus, *nac-nac*, sea gull; *cug-eny*, woodpecker. There are two cases, nominative and oblique, as *taru-ti-po* (courser of heaven), the sun; *taru-niep* (heaven-rest), the moon. The plural and comparative are denoted by *ruhu*, more; the superlative by *yikaram*, most. In conjugation there are two moods, infinitive and participles. There is no substantive verb; thus: *he mung*, he gone; *e reha*, it good, &c. Among the Brazilian tongues is that of the Canaëans on the river Pardo, in the province of Bahia, with extremely long words, very abrupt peculiar final sounds, and many gutturals; and that of the Macharis in Porto Seguro, with most peculiar palatals and many nasals. For materials on the Brazilian languages, see the works of Léry (1578); Mimiani, on the Kiriris (1695); F. de Azara (1781); Prince Maximilian of Newwied (1815-'17); Spix and Martius (1817-'20); Von Eschwege's vocabularies of the Puris, Coroados, Coropos, &c.; and the travels of D'Orbigny and Auguste St. Hilaire.—The Araucanian or Chilidugu, Chili language, formerly extended more northward, and is spoken by the Picunches, from Coquimbo as far as Santiago, by the Puelches about Mendoza (E. of the Cordillera), by the Huilliches on the Biobio and Valdivia, and by the independent Aucas in the south of Chili, with dialectic variations. This is probably the most harmonious and the most cultivated language among the indigenous races; its purity and elegance being so cherished, that even a preacher is often upbraided by his hearers if he commits a solecism in his sermon. It has not the Spanish aspirated *j*, *g*, nor *x*, *z*, *b*, *f*; but has a nasal *n* and *u* as in French. In the north, *d* and *r* are used for *s*, and conversely in the south. Words end in vowels and in the mild consonants, *b*, *d*, *g*, *f*, *l*, *m*, *n*, *r*; only about 20 in *s* or *z*. There is no gender; the signs of sexes are *alea*, male, and *domo*, female. The cases are three, formed by adding *ni*, genitive; *no*, *men*, ablative; *egu*, instrumental. Dual, *engu*; plural, *ica*, *egn*, or by prefixing *pu*, or intercalating *que* between adjective and substantive. Persons: *inche*, I; *imí*, thou; *taye*, he; dual: *inchu*, 1st; *imú*, 2d; *taye epu*, 3d; plural: *inchiñ*, we; *imn*, you; *taye eulá*, they. Personal suffixes to verbs: 1, *n*; 2, *imí*; 3, *i*; dual, *yu*, *imú*, *igu*; plural, *iñ*, *imn*, *ign*. The imperfect tense is formed by intercalating *vu*; future, *a*. The infinitive ends in *n*; gerunds in *uam*, *uum*; the participle active in *lu*, pas-

sive in *el*; the conjunctive in *li*, optative in *lichí*; passive voice in *ngen* (thus, *aiñn*, to love; *aiñngen*, to be loved); negation intercalates *lu* (imperative *queb*). There are more than 20 forms of transition for all sorts of modifications in the verb (more than in the Altaic languages). In short, some of the best traits of the Indo-European and the polysynthetic languages are combined in the Chilidugu. It has geometrical terms, and is skilfully employed as a rhetorical and poetical idiom. There are grammars and vocabularies by L. de Valdivia (Lima, 1607), A. Febres (1765, 1846), and B. Havestadt (Münster, 1777). The Patagonians (Tehuelhets) are divided into several tribes, such as the Tehuel-cunny (South-men), Tehuan-cunny, (North-men), &c. Falkner, an English Jesuit, gave a grammar and vocabulary of the Moluches (Hereford, 1774). It is supposed that an idiom similar to theirs is spoken by the Yacanaëns, who inhabit Tierra del Fuego and the southern margin of the continent, as well as the Brunswick peninsula.

AMERICANISMS. There were peculiarly strong influences in America to cause variations in the English language from the standard of the mother country, such as the thinness of population; the novelty of numerous objects, of the mode of life, and of the system of government; the vast influx of persons speaking the languages of continental Europe and Africa; intercourse with the red men; the want of a metropolis, a court, and permanently wealthy families, which might serve as authorities; and the adoption by newspaper editors of the slang words of the multitude. But there have also been very strong influences at work to protect the English language in America from variations. These influences have been, a more extensive and thorough popular education than that of any other country, the almost universal habit of reading, an intercourse between distant districts by travelling unequalled in any other part of the world, and the extensive use of dictionaries. The consequence is, that there is more uniformity in the English language as spoken in the United States than in the tongue of any other people equally numerous; every American can with ease understand every other one; and it may safely be said that as a people the Americans speak English better than the English themselves. But the standard of the correct language still remains in the use of the learned and educated people of England.—Americanisms are of various kinds, viz.: First, new words, such as *sparse*, *backwoods*, *caucus*. Secondly, old English words in new meanings, as *block*, meaning the land or houses enclosed between four streets in a town or city; *realize*, meaning to conceive as actual; and *section*, meaning a square mile of land. Thirdly, words which were provincial in England adopted in general American use, as *wilt* for *wither*. Fourthly, words which have remained in America the meaning they had in England several hundred years ago, while in the

latter word the meaning has been changed. The word *silk* is an example of this. Fifthly, words preserved in American use, which have become obsolete in England; such as *tarry*, *freshet*. Subjoined we give a list of some of the most noteworthy Americanisms, many of which are occasionally used in American newspapers, while almost all are frequently employed in conversation by the less educated people. A large proportion are of course mere vulgarisms, never used by Americans of any culture. It deserves to be remarked that many Americanisms current in the southern, western, and middle states, are not used in New England, where the language, at least as written, approximates more closely to that of the mother country.

Approbate, used instead of approve.

Bud, used in the sense of ill.

Baggage, used to signify the trunks, boxes, valises, clothing, &c., of a traveller. The English say *luggage*, and consider baggage pretentious.

Balance, meaning remainder; as, "Two of the professors were dismissed, but the balance were retained."

Board, always used to signify all kinds of boards. In England pine and fir boards are ordinarily called "deals."

Boypis, meaning counterfeit, false, fraudulent.

Border, in the sense of a greensward or line of flowers bordering on a wall, in a garden or yard; called an edging in England.

Boss, meaning an employer or superintendent of laborers.

Brush, for brittle.

Brushstuffs, much objected to by English writers 20 years ago, but now admitted to be a good word.

Buggy, denotes a light four-wheeled wagon; in England it means a two-wheeled carriage.

Buncombe, used in the phrase to "speak to Buncombe," meaning to speak only to catch the applause, or favor of the vulgar. This phrase, often abbreviated "to talk Buncombe," was derived from the name of Buncombe county, N. C. A representative in congress from this county was wont to make speeches to which no one listened; observing the members leaving the house while he was speaking, he one day declared that he cared little how many left—he was not speaking to the house, but to Buncombe. The phrase soon came to mean any speech made solely to please a constituency or the public.

Bureau, universally used to the exclusion of the English "chest of drawers."

Calculate, used in the sense of think, suppose; as "I calculate I can do it."

Calico, in the United States, means printed cotton goods; in England it means only white cotton cloth.

Caption, used in the United States to mean the heading of a chapter, section, or page, is not used in England.

Cleric usually means good-natured, obliging, in America, and quick-witted or intelligent in England.

Conclude is used by Americans in the sense of determine, as, "I have concluded to go." In Great Britain it is used to signify the formation of an opinion, not of an intention.

In this connection is a phrase much used in the United States, and appears to have been first brought into currency about 60 years ago, chiefly in New England periodical literature. English writers would prefer to say, "in connection with this subject."

Corn means only maize in the United States; in England it means grain generally.

County, in America, is ordinarily used after the proper noun used to designate particular counties, as "Pike county," &c. The English always say "county of," as "county of Lancaster;" and the Irish say "county Wexford," &c., omitting "of."

Creek, in most of the American states, means a small river; in England it means a small arm of the sea.

Creole properly means a person descended from European parents, born in some portion of America which belongs or did once belong to Spain; but the Americans often use the word to designate a native of the South tinged with negro blood.

Deadhead, a person who has the use of public conveyances, the telegraph, or the mail, admission to public entertainments, &c., without payment. The transitive verb *to deadhead* is sometimes used.

Declination, the refusal to accept a nomination to office.

Dry goods, a general term used by Americans to signify such articles as are sold by linen drapers, haberdashers, mer-

cers, drapers, hosiers, &c. The word "haberdashery" is almost unknown to the United States.

Dress, the word almost universally used by American women to designate their gowns.

Elected, used intrinsitively in the sense of choose; as, in a division of property, "He elected to take the real estate."

Entorse, a word adopted from commercial usage to signify sanction, approve, confirm.

Entreaty, meaning to result in.

Expect, misused in application to past events; as, "I expect it was."

Fall, meaning autumn.

Fancy, used as an adjective to signify fantastic, various. It is frequently used on signs of shops where assorted goods are sold; thus, "Fancy Store." Whatever is ornamental rather than useful, fantastic, adapted to gratify luxurious tastes rather than necessary wants, more elegant than substantial, figured as opposed to plain, may be described as "fancy." Thus there are "fancy silks," "fancy horses," &c. For analogous reasons the term is also applied to certain classes of men and women.

Fish-dealer, the American name for a fishmonger.

Fix in England means to fasten or make firm; in America it means almost anything in the way of putting in order, adjusting, mending, setting to rights, or making.

Fleshy for stout.

Freshet, meaning a flood, is not recognized in England as a good word; but it was used several centuries ago by good English writers.

Frock is the name sometimes given by American women to their gown. Ogilvie says frock is now used in England "for a loose garment or shirt worn by men over their other clothes, and for a kind of gown, open behind, worn by females."

Fruit-dealer, the name generally given in the United States to fruiterers and green-grocers.

Gerrymander, a method of arranging election districts so that the political party making the arrangements will be enabled to elect a greater number of representatives than they could on a fair system of districting, and more than they should have in proportion to their numerical strength. The word was derived from the name of Elbridge Gerry, a signer of the Declaration of Independence, who was accused of being the first to practice this species of fraud on the rights of the people while governor of Massachusetts.

Go ahead is of American origin, and is used by Americans in cases where the British would say "All right."

Guess, used as "think;" as, "I guess I do." "I guess so."

Hack usually means a hackney-coach in America; in England it means a lively stable horse, or one merely used for travelling and routine work.

Hardware merchant, or *hardware dealer*, is the American name for an ironmonger.

He's is frequently used in the United States to signify servant, servants, or service.

Hold on is a common Americanism for "stop." It is probably derived from the German *halten an*.

Homey means plain-faceted or ugly in the United States; in England, it means pertaining to home, plain, simple, unadorned.

Improve is an Americanism for opening a farm on wild land by cutting away the wood and brush, erecting buildings and fences, ploughing the ground and putting it in order. The buildings and fences are styled improvements.

Levee, in the United States, is often applied to ceremonious reception parties given by official personages, whether in the morning or evening. In England the word is restricted to morning receptions.

Loafers, Americanism for loungers or vagabonds.

Loin, frequently used in the United States as a verb, but seldom in England, where lend is the usual word.

Lobby, verb, to attempt to exercise an influence on members of a legislative body by persons not members.

Locate, to determine and designate the place of, to settle in.

Logrolling (with the verb *to logroll*), a system of management by which a member of a deliberative or legislative body attempts to secure the adoption of a favorite measure, by inducing other members to vote for it in return for assistance in carrying their several pet measures. It originated in the mutual aid of the early settlers in clearing trees from the land.

Lot, a small tract of land, such as the subdivisions in towns. The English usually say "allotment."

Lumber means trash in England; in the United States, sawn wood for building and other mechanical purposes. Lumbering means making lumber; lumberman, one engaged in making it; and lumber merchant, one who sells it.

Mad is frequently used by Americans to signify angry; it is not so used by the English.

Mail is the ordinary word used in the United States to express the ideas conveyed by "post" in England. Americans say "mail a letter," "send it by mail." In such expressions the English say "post."

Molasses is used in the United States to signify treacle as well as molasses. Properly, the former is the drainage from sugar in the process of refining, the latter from sugar in the process of making. Molasses comes from the sugar plantations, treacle from sugar refineries.

Narrate has been objected to as a bad Americanism, but it is used by English authors, is found in English dictionaries, and is of English origin.

Necessitate is an Americanism much objected to by English writers.

Nightfall and *afternight* are expressions common in the United States, but not used in England.

Notify, in the United States, means to give notice to; in England it means to make known. The American says, "You must notify the drawer of the protest." The Englishman says, "The protest must be notified to the drawer."

Obligate, sometimes used by American writers, is objected to by English lexicographers as a low word.

Obnoxious is used much more frequently in the United States than in England, where offensive is preferred.

On is often used by Americans in such phrases as, "He lives on a street," "He took passage on a steamboat," &c. The Englishman would use "in."

Pantaloon (or more commonly *pants*), the common American name for trousers.

Pipe-laying, fraudulent voting, and schemes or means to obtain fraudulent votes. The word had its origin in New York, at the time of the construction of the Croton water works. Some leaders of the whig party were charged with having made arrangements to bring a large number of men from Philadelphia, ostensibly to lay pipes for the water, but really to vote at an approaching election.

Pond, a pool or body of water smaller than a lake, with either natural or artificial banks. In England, "pond" implies that the water is confined by an artificial bank.

Posted, well informed, thoroughly conversant with.

Quite, in the sense of "very," is in universal use by Americans, in such phrases as, "It is quite cold."

Railroad, railroad track, railroad depot, and railroad car, are the American names for the English railway, railway line, railway station, and railway carriage. The American travels "in the cars," the Englishman "by the rail." In the United States the iron horse is ordinarily a "locomotive;" in Britain it is an "engine."

Rapids, that portion of a river where the current is so swift that the surface of the water is broken by short waves or by low falls.

Reckon, used in the southern and western states instead of suppose, think; as, "I reckon he does;" "That'll do, I reckon."

Reliable, for trustworthy, has been adopted in the common use of England, but is not employed by careful writers.

Ride, in the United States, means riding either in a wagon or on horseback. The English restrict "ride" to horseback. In America, "to drive" means to hold the reins; in England it does not. *Ride* was formerly used by the English as it is now used by the Americans.

River is always placed by the English before the proper name when speaking of a particular stream, as "the river Thames." The Americans generally place "river" after the proper name as "the Ohio river."

Roll, to render turbid, a provincial word in England, is in general use throughout the United States, where it also means to make angry.

Rooster is an Americanism for "cock," a male barn-door fowl. *Sick* is the ordinary American word for ill, but is used by the English chiefly to express sickness at the stomach.

Skeeladdle, to run away—a word introduced during the civil war, and at that time in general use.

Sledge, for the English "sledge." The English go "sledge-driving," the Americans go "sleigh-riding."

Span is an Americanism for pair, applied only to horses or mules. It is derived from the German *Gespann*.

Stage, for stage coach; rarely so used by the English.

Stall is used in the United States to signify stirk fast; as, "The horses are stalled." "The wagon is stalled," &c.

Steop is an Americanism, derived from the Dutch, meaning the steps at the entrance of a house, doorstep, a porch, a piazza, a platform of stone or wood before a door.

Store is the usual American name for a shop; and shop is rarely used except to designate a place where mechanical labor is done. Such terms as "book store," "shoe store," "grocery store," "liquor store," "drug store," are always used by the Americans to the exclusion of "book shop," &c.

Suspenders is the proper, as well as the vulgar, American name for the articles known in England as braces.

Suspicion is sometimes used in western American newspapers as a verb instead of suspect.

Switch, in speaking of railroads, as, "to switch off." The English say "shunt."

Turner, a place where travellers are entertained and lodged. In England it means a place where liquors are sold and entertainment (but not lodging) is provided for parties.

Ticket is used by the Americans in many ways unknown to the English. Politically it means a list of candidates at an election. When an American engages a passage on a railroad, he purchases a ticket; the Englishman is booked at the office. The American purchases a "through ticket" or a "way ticket;" the Englishman is booked for a portion or the whole distance of his intended journey.

Timber, in the sense of forest or grove; as "the house stands at the edge of the timber."

Transient, in such phrases as a "transient person," meaning a person staying at a place for a short time, a stranger, a traveller, is not used in that sense in England.

Venison, deer meat; in England, wild meat generally.

Wagon or *wagon*, according to the usual American spelling, is frequently used in the United States as a verb; thus, "The goods were wagoned across the mountains."

Will is generally used by the natives of the southern, western, and middle states, in the first person, instead of shall, when they merely wish to express an expectation.

Woods is the common American name for what the English term "a wood."

Vocabularies of Americanisms have been published by John Pickering (Boston, 1816), John Russell Bartlett (New York, 1848, new ed., revised, 1859), and Prof. Schele de Vere (New York, 1872). Such multitudes of slang words are made every year in America and circulated by careless or flippant writers, that if they were all collected they might before long equal in number the 60,000 provincialisms of England. Fortunately they are generally used with a knowledge of their vulgarity, and many of them are forgotten almost as easily as they are coined.

AMERICAN RIVER, in N. central California, is formed by the union of its N. and S. forks near the W. boundary of El Dorado county, 30 miles above Sacramento city, flows S. W. between the counties of Placer and Sacramento, and falls into Sacramento river near that city. The N. fork, considered by some as the true American river, rises among the hills at the base of the Sierra Nevada, and flows W. S. W., forming the boundaries between Placer and El Dorado counties for 100 miles. The S. fork flows from Bonpland lake through El Dorado county, and forms part of the division between the counties of Sacramento and El Dorado. These streams pass through one of the principal gold-mining districts.

AMERICAN WINES. From the first settlement of America, the vine attracted the attention of the colonists, and as early as 1565 wine was made from native grapes in Florida. The first vineyard in the British colonies was planted by the London company in Virginia in 1620, and in 1630 French vine-dressers were imported by them; but the enterprise failed. Wine was made in Virginia in 1647, and in 1651 premiums were offered for its production. Beverly mentions that prior to 1722 there were vineyards in that colony, producing 750 gallons per year. In 1664 governor Richard Nicolls of New York granted to Paul Richards the privilege of making and selling wine free of duty, as the first who entered upon its cultivation on a large scale. Beauchamp Plantagenet, in a description of New Albion in 1648, states that the English settlers in Uvedale, now Delaware, had vines running on mulberry and sassafras trees. He names four kinds of grapes: Tou-

louse muscat, sweet-scented, great fox, and thick grape. The first two, after five months, being boiled and salted and well fined, made a strong red sherry; the third, a light claret; the fourth, a white grape, which crept on the ground, made a pure, gold-colored wine. Tennis Pale, a Frenchman, made out of these four eight sorts of excellent wine; and his muscat after four months would intoxicate a man with the second draught. In 1683 William Penn tried to establish a vineyard near Philadelphia, but without success. A few years later, however, Mr. Tasker of Maryland, and Mr. Antill of Shrewsbury, N. J., seem to have succeeded somewhat better. In 1796 the French settlers in Illinois made 110 hogsheads of strong wine from native grapes. At Harmony, near Pittsburgh, a vineyard of 10 acres was planted by Frederick Rapp and his associates from Germany, and they continued to cultivate grapes and silk at their new colony of Harmony in Indiana. In 1790 a Swiss colony was founded in Jessamine county, Ky., to establish a vineyard, but failed, as they planted only foreign grapes. They removed to Vevay, Switzerland county, Ind., in 1801, there planted native vines, especially the Cape or Schuylkill muscatel, and had more success. After 40 years' experience, however, they seem to have become discouraged.—The wines and wine grapes of America may be divided into wines of the Atlantic coast and wines of the Pacific coast. They are so entirely distinct that they can hardly be compared. The wines of the first division resemble more those of Germany and France, containing more acid, more sprightliness, flavor, and bouquet; while the wines of the Pacific coast, especially California, contain but little acid, a good deal of spirit, and little flavor or bouquet, thus more nearly resembling the wines of Spain and southern Europe. The cause for this may be sought partly in the soil, but mostly in climatic influences. It is well known to wine makers that the grape must contain a certain amount of acid to develop bouquet during fermentation of the must and its transformation into wine; while the heat of the southern climate develops the largest amount of sugar in the fruit, the acids diminish.

I. WINES OF THE ATLANTIC COAST. These may be divided into three distinct classes: 1, white or light-colored wines; 2, red or dark-colored wines; 3, wines resembling sherry.

1. *White Wines.* The Catawba grape was first introduced by Major Adlum of Georgetown, D. C., having been found by him in Maryland. It was first planted on an extensive scale by Nicholas Longworth, who may be called one of the founders of American grape culture. He leased parcels of unimproved land near Cincinnati to German settlers to plant with vines for one half the proceeds. In 1838 the whole number of acres planted in vines around that city, mostly Catawba, was estimated at 1,200, of which Mr. Longworth owned 120. The principal pioneers in the business there,

and extensive wine makers, are Messrs. Werk, Buchanan, Mottier, Bogen, Rehfuß, and Thompson, all owners of large vineyards and extensive manufacturers of still and sparkling wines. At Hermann, Mo., the Catawba was introduced in 1846, and bore its first fruit in 1847, when excellent wine was made from it on a small scale. Shortly afterward it was also introduced into Illinois. In 1860 the Pleasant Valley wine company was formed at Hammondsport, Steuben county, N. Y., which also cultivates it largely. But it is more extensively cultivated on the shores of Lake Erie than anywhere else, where the soil on Kelly's Island and Put-in-Bay, and around Cleveland and Sandusky, seems to be well adapted to it. It makes a light-colored wine, sprightly and aromatic, which is perhaps better known and has been longer appreciated than any other wine in the country. It varies very much with the different locations, the wine of New York, northern Ohio, and northern Illinois containing less spirit, but a high flavor and a good deal of acid, while the wines of Missouri and further south are smoother, heavier, and less acid and astringent. Although the vine is very uncertain in its product, being much subject to disease, there is more Catawba wine consumed now than perhaps all other varieties together, both still and sparkling. It makes an excellent sparkling wine, which many connoisseurs prefer to the imported; and as a still wine it resembles the light Rhine and Moselle wines of Germany, though of course with a peculiar characteristic flavor. Average specific gravity of must, 80° Oechsli; acid, 5 per M. The Isabella is a native of South Carolina, and was first introduced in the north and brought to the notice of cultivators by Mrs. Isabella Gibbs. It has been nearly superseded by better sorts. Its wine is pale pink, light and somewhat flat, hardly ever met with now except as sparkling, for which it is well adapted, though in every respect inferior to Catawba. Sp. gr. of must, 65°; acid, 6. The Cassidy originated in Philadelphia, in Mr. Cassidy's dooryard. Wine fine straw color, good body and fine flavor, strongly resembling the wines of the Palatinate. It is not much cultivated. Sp. gr. of must, 90°; acid, 4. The Diana is a seedling of the Catawba, raised by Mrs. Diana Crehore, Boston. Its wine is seldom met with alone, as its flavor is too strong, and the must is mixed with other grapes. It has little value as a wine grape. The wine is pale straw color, less sprightly than Catawba, with strong foxy flavor. Sp. gr. 80°; acid, 4. The Goethe, Rogers's hybrid No. 1, originated by Mr. Rogers of Salem, Mass., is a hybrid between *labrusca* and *vinifera*. The wine is very pale, almost white, of a delicate muscatel flavor, sprightly and ethereal; a very fine light still wine, surpassing Catawba, and no doubt well adapted for sparkling wine, though of too recent origin to have had a fair trial. Sp. gr. of must, 80°; acid, 4. It is extensively raised at the west as a wine grape. The Lind-

ley, Rogers's No. 9, is of the same origin as the last. The wine is somewhat heavier and stronger flavored, resembling Catawba in color and taste. It promises well. Sp. gr. 90°; acid, 5. The Massasoit, Rogers's No. 3, of the same origin. Wine straw color, fine flavor and body, superior to Catawba in every respect. Very promising, though but little wine has yet been made of it. Sp. gr. 95°; acid, 5. The Salem, Rogers's No. 22, of the same origin. Wine straw color, too aromatic to be pleasant, though of heavy body. Sp. gr. 92°; acid, 4. The Martha is a seedling from the Concord, and originated with Samuel Miller of Lebanon, Pa. It first fruited in 1863. Wine straw color, of good body, less sprightly and more foxy than Catawba at first, but improves greatly by age; and as the grape is very hardy and productive, succeeding everywhere, it may become one of the leading white wines of the country for general consumption. Sp. gr. 90°; acid, 4. The Maxatawney originated at Eagleville, Pa., in 1844. Wine very delicate and smooth, pale yellow, resembling Rhine wine in character; a fine wine, which will be appreciated as soon as it becomes better known. Sp. gr. 80°; acid, 4. The North Carolina seedling was produced by J. B. Garber, Columbia, Pa., from seed of the Isabella. Wine dark yellow, of fair body and good flavor, if pressed immediately; about equal to good Catawba, with more muscatel flavor. Sp. gr. 80°; acid, 5. The Iona was originated by Dr. C. W. Grant, of Iona Island, N. Y. Wine pale yellow, of good body and fine flavor, superior to Catawba. It is extensively raised as a wine grape in some parts of its native state, and were it not so uncertain, its wine would become one of our leading varieties. Sp. gr. 90°; acid, 5.—The above belong to the class of *labrusca*, or fox grapes. The following belong to the *astivalis* class, destined to make the finest wines, white as well as red, yet produced in the United States. The precise history of the Delaware grape is unknown. It was first introduced to the public and disseminated from Delaware, Ohio. The wine is of a yellow color, fine flavor, and great body, resembling some of the finer Rhine wines, especially the Traminer of Germany; a very good still wine, though not so well adapted to the manufacture of sparkling. As the grape does not succeed everywhere, it will be confined to certain localities. Sp. gr. 100°; acid, 4. The Herbermont or Warren was, according to the best authorities, first cultivated by Mr. Neal, a farmer of Warren county, Ga., in 1800. In the early settlement of the country he found the vine in the woods, and transplanted it. Its productiveness and fine flavor attracted attention, and it spread over the state. Mr. Herbermont, of Columbia, S. C., a native of France and an enterprising grape grower, cultivated it largely, and thought it had been imported from France, and belonged to the *pineau* class—an opinion which some of our vintners yet entertain. It

was named in honor of him Herbermont, or Herbermont's Madeira. It was by him sent to Mr. Longworth at Cincinnati, and from there introduced at Hermann, Mo., by Mr. Charles Teubner, in 1847. Mr. Herbermont made for many years a very superior wine from this grape, and reported a yield in one season of 1,500 gallons to the acre. It is now more and more appreciated as a superior wine grape for the west and south, on dry limestone soils. Its juice, if pressed before fermentation, makes a very delicate white wine, resembling the finer qualities of Rhine wine, more sprightly than any other grape, and consequently well adapted to the manufacture of sparkling wine. It is a true wine grape, without pulp, and very juicy; and after fermentation a fine red wine can be pressed from the skins, which contain the coloring matter. Sp. gr. 90°; acid, 5. The Louisiana was introduced into Missouri by Frederick Münch of Warren county, who received it from Mr. Théard of New Orleans about 1855. Mr. Théard was positive that it had been imported from France, but it is so nearly related to the Herbermont that a mistake may have occurred. Its wine is perhaps the best of its class we yet have in America, fully equalling the finest Rhine wine, of fine golden color, exquisite flavor, and great body, smooth and rich, but is yet very scarce and high-priced. It is a true cabinet wine. Sp. gr. 110°; acid, 5. The Rulander or St. Genevieve was first cultivated at St. Genevieve, Mo., by some of the French settlers. It was first brought to the notice of the vine growers at Hermann by Mr. Louis L. Koch of Goleconda, Ill., under its present name of Rulander, and is now extensively cultivated there. Mr. Peter Weitzenecker, near St. Louis, also cultivated it at an early date, under the name of Rothelben. Its wine is of golden yellow color, sometimes having a brownish yellow tint, with great body and very fine flavor, standing midway between a choice hock and a sherry, having some of the characteristics of both. It was awarded the first premium as the best light-colored wine at Cincinnati, Ohio, in 1868, about 25 varieties of the choicest wines competing. Sp. gr. 110°; acid, 5. The Taylor or Bullitt originated with Judge Taylor of Kentucky. It is the only white wine grape belonging to the *cordifolia* class of which wine has yet been made. It makes a wine of a straw color, of fine flavor, closely resembling the German Riessling, heavy body, and very sprightly. Were the grape a surer crop than it has yet proved to be, it would be extensively cultivated. Sp. gr. of must, 100°; acid, 5½. 2. *Red Wines.* In the *labrusca* class of grapes the Concord takes the lead, as it will succeed anywhere, on any soil, and is healthy, hardy, and exceedingly productive. There is perhaps as much wine made from it as from the Catawba, and it is effectually and truly the poor man's wine, as it can be produced very cheaply, and has a peculiar enlivening and in-

vigorating effect upon the system. For a light summer wine it has not its equal as yet, and ought to supplant all the cheap French clarets, as it is better, more wholesome, and can be made cheaper. It originated with Mr. Bull of Concord, Mass., about 1854, but was not fully appreciated at the east. In 1855 it was introduced into Missouri by George Husmann of Hermann, and also about the same time or somewhat later by Frederick Münch of Warren county. The first wine was made of it by George Husmann in the autumn of 1857. It found universal favor, and the wine spread rapidly over the western states. Now it is raised everywhere and has become the grape for the million. Its fruit and wine are much finer at the west than at the east. The wine, if fermented on the husks, varies from bright red to dark red, has a strong native flavor resembling strawberries, is slightly astringent, sprightly, and invigorating. If the grapes are pressed as soon as mashed, it makes a white or yellow wine, which is now coming into use as a substitute for Catawba. It also makes a very fine sparkling wine, and is largely manufactured into the latter variety. Sp. gr. 75°; acid, 5. The Creveling, Bloom, or Catawissa originated at or near Catawissa, Columbia county, Pa. It makes a claret wine of very fine flavor, without the foxiness of the Concord, and which finds more favor with Europeans than the Concord. It is but moderately productive, however, and, although a finer table grape than the Concord, will hardly become so popular as a wine grape. It has much of the *astivalis* character, and may be a hybrid between *labrusca* and *astivalis*. Sp. gr. 75°; acid, 5. The Hartford prolific is an old variety, raised by Mr. Steele of Hartford, Conn. Its wine is very light and foxy, otherwise resembling Concord in color and character, but hardly so good. It is but little cultivated as a wine grape, although it yields abundantly. Sp. gr. 70°; acid, 5. The Ives is an accidental seedling produced by Henry Ives, near Cincinnati, Ohio, whence it was disseminated all over the west. It is productive and hardy, but has been much overpraised. Its wine is a fair claret, with a less foxy flavor than the Hartford or Concord, of a dark color and a good deal of astringency, in quality midway between the Concord and Norton, as produced at the west. Sp. gr. 80°; acid, 6. Rogers's hybrid No. 2 originated with Mr. Rogers of Salem, Mass., and, though hardly thought worthy of a name at the east because of its late ripening, is valuable at the west, being productive and hardy, and producing a wine of a brilliant red color, fair body, and peculiar but agreeable flavor, very sprightly and refreshing. Sp. gr. 80°; acid, 5. The Wilder (Rogers's hybrid No. 4), of the same origin, is very productive, and makes a pleasant, light red wine, of not much character, but a good summer drink, generally preferred to Concord. Sp. gr. 78°; acid, 4. The Tele-

graph originated in a dooryard near Philadelphia, and was first disseminated by Major Freas of the "Germantown Telegraph." The vine is very productive, healthy, and hardy, and makes a fair wine, of claret character and agreeable flavor. Sp. gr. 80°; acid, 5. —Among red wine grapes of the *astivalis* class, the Alvey or Hagar, introduced by Dr. Harvey of Hagerstown, Md., is one of the best grapes in quality, succeeding well in many parts of the south. Its wine resembles the finer Bordeaux wines in character and flavor, and, if the grape should prove adapted to extensive cultivation, would soon become very popular in the market. Sp. gr. 90°; acid, 5. The Cynthia was introduced to general culture by George Husmann of Hermann, Mo. It is supposed to have originated in Arkansas; hence its synonyme, Red River. Cuttings were received from William R. Prince of Flushing, N. Y., about 1858. The vine closely resembles Norton's Virginia, but the fruit is sweeter and more juicy, and the wine of an entirely different character, resembling the choicest Burgundy, very dark, of great body, and an exquisite spicy flavor. It is one of the best, if not the best of American red wines, and may safely enter the lists with the best brands of Burgundy; while the hardiness and productiveness of the vine makes it well adapted to general cultivation. Sp. gr. 180°; acid, 4. The Devreux is a southern grape, closely related to the Herbeumont. It is very uncertain in its crop, but makes a splendid dark red wine of the Burgundy class, the only rival to the wine of the Cynthia now produced, and perhaps surpassing it in smoothness and delicacy, though not as aromatic and spicy. Sp. gr. 105°; acid, 4. Norton's Virginia (erroneously called Norton's seedling) was introduced by Dr. Norton of Richmond, Va., and was found by him on an island in the James river. It was first popularized by the grape growers of Hermann, where it was introduced about 1850 by Mr. Heinrichs of Cincinnati, and Dr. Kehr from Wheeling, Va. After a long and patient trial, it has gradually spread over the west to such an extent that its wine is known and made everywhere, and recognized as the best medical wine of America. It is dark red, almost black, very heavy, astringent, and of strong flavor, somewhat resembling the flavor of green coffee. It is a remedy against bowel complaints, chronic diarrhoeas, and summer complaints in children, and as such will hardly be equalled by any other wine, either of Europe or America. It is also a preventive of intermittent fevers and other malarious diseases, and has already been appreciated in Europe as one of the best red wines of the world. Sp. gr. 110°; acid, 4. —Of the *cordifolia* class, the Clinton originated in New York about 1832. It is extensively planted, and a good deal of wine is made from it, especially in the northern states; but it is a very rampant grower, and much subject to the attacks of the gall louse. It makes a

good dark heavy claret, if the grapes are well ripened, with rather a pleasant wintergreen flavor, liked by some. Sp. gr. 90°; acid, 6. The Franklin, probably a seedling of the foregoing, is very productive and hardy, and produces wine of similar character but inferior to Clinton. Sp. gr. 80°; acid, 6. The Marion, belonging to the same class, makes a fair red wine, but is hardly worth cultivating when better varieties are abundant. Sp. gr. 83°; acid, 6. 3. *Sherry Wines*. The Cunningham originated in the garden of Mr. Jacob Cunningham, Prince Edward county, Va., about 1812, and proved so thrifty and hardy that it covered an arbor 50 feet long and 12 feet high. Mr. Samuel Venable then cultivated it to a certain extent in his vineyard in Prince Edward, and was probably the first who made wine from it, very much resembling Madeira. It is now largely cultivated at Herrmann and Bluffton, Mo. Its wine is brownish yellow, of great body, and fine, sherry-like flavor; and as the vine is a rampant grower and abundant bearer, it would be a favorite grape were it not somewhat tender, and only adapted to dry hillsides. Sp. gr. 100°; acid, 6. The Herrmann originated with Francis Langendörfer, near Herrmann, Mo., and first fruited in 1865. It is a seedling of Norton's Virginia, exceedingly hardy, healthy, and productive. It may be too late for extreme northern localities, but is certainly one of the most profitable varieties for the west and south. The wine, if properly handled, is of a brownish golden color, with true sherry flavor, very heavy, and exceedingly fragrant and spicy. Connoisseurs have preferred it to the finest imported sherries. Sp. gr. 105°; acid 4.—*Wines of the Southern Atlantic States*. There are two species of the vine exclusively confined to the southern states, which will not succeed north of the Potomac, and on the value of which for wine authorities still differ. 1. *Vitis vulpina* or *rotundifolia* (the muscadine or Bullace). To this species may be referred the Scuppernong, and its seedlings, the Thomas, Flowers, and Mish. The vine is entirely different from any other species, the bark being smooth, the leaves round and glossy, and the fruit produced in clusters of from three to twelve berries, which drop from the stem when fully ripe. As wine has generally been made at the south so far by an addition of sugar and even alcohol, it is very difficult to judge of its true merits. One of the best wines is made by Germans at Aiken, S. C., where there are very extensive vineyards. The white Scuppernong seems to be deficient in sugar, as its must seldom ranges above 60°, and to contain so much gluten that it is very sluggish in fermentation. But although most of the must, even now, has sugar or alcohol added to it in fermentation, it seems that a good still and also sparkling wine may be made of it; and as the grape produces abundantly, and is very healthy, it may become a great source of profit to the south. Its wine is generally pale yellow, of strong flavor and

heavy body, and the vines are said to produce after the 10th year from 750 to 1,500 gallons to the acre. Sp. gr. 60°; acid, 4. 2. *Vitis mustangensis*, or mustang grape. This is found in great abundance in the woods of Texas, where it climbs to the tops of the highest trees. So far as known, no attempts have been made to cultivate it. The berry is large, black or purple, and contains a very acid juice. It is said to produce a wine resembling claret, and considerable quantities are made from the wild vines every autumn. II. WINES OF THE PACIFIC COAST. "The history of grape culture in California," says Charles Reukl in his work "California," "takes its rise in the southern districts of the state. The vine was introduced in the middle of the last century by the Catholic missions. The pious monks had brought their native thirst from the sunny fields of Spain, and longed to quench it in California. They began by sending for large numbers of Spanish and French cuttings, which, however, were found not to thrive when planted. They grew, but bore little fruit, and only at intervals. A ship which brought the monks their regular supplies once had some fine raisins on board. One of the missionaries planted the seeds, and the experiment succeeded; the vines flourished to admiration, and bore superb grapes. Large plantations were then made, with the aid of the Indians, at the mission of San Gabriel, in Los Angeles county." The grape originally planted by the missionaries is called Los Angeles, and was the only one cultivated in California to the year 1820. At that date a new variety was introduced in the Sonoma valley, believed to have been brought from Madeira. This new variety, and the old one of the missionaries of Los Angeles, are known as mission grapes, or California grapes, and still constitute two thirds of all the vines grown in the state. New varieties, however, have been introduced, partly from Europe, especially Germany, and partly from the Atlantic states. At the present day some 200 kinds of grapes are raised and tried in California, all of which seem to succeed. Those most frequently met with are: of European or Asiatic origin, the Riesling, Tokay, muscatel, black Hamburg, Chasselas; of American origin, Catawba, Isabella, Concord, Ives, Herbemont, Delaware, Diana, Salem, and many others. The intelligent and workmanlike culture of the vine, and the management and sale of its products, are of recent date. The long experience of other countries is still wanting there, so that many and grave difficulties are encountered. For some time the vine was usually planted in level river bottoms, and even on wide plains, and the vines were supposed to require artificial irrigation. It is now ascertained that the vines planted on the slopes of hills, as is usual in Germany and France, succeed far better than the vineyards on open plains, and produce wine generally heavier and of finer flavor. The largest vineyard in California is that of the

Buena Vista company in the Sonoma valley, which contains 450 acres and 306,000 vines. The same valley, which is very beautiful, sheltered against the winds, and free from fog, also contains the Rhine farm, laid out by Mr. Jacob Gundlach, in company with Mr. Emil Dresel. Gen. B. D. Wilson of San Gabriel has also 260 acres in vines. The total number of vines growing in California at the opening of 1870 was 22,548,315. The counties most actively engaged in grape-growing are Los Angeles, 4,000,000 vines in 1870; Sonoma, 3,250,000; Sacramento, 1,718,914; Amador, 1,683,000; El Dorado, 1,357,895; Solano, 1,128,000; Santa Clara, 1,000,000. In 1868, 2,676,550 gallons of wine and 161,015 of brandy were produced. According to local authorities, the wine yield of the state for 1870 was from 4,000,000 to 5,000,000 gallons, although the federal census of that year gives only 1,814,656. The "Wine Dealers' Gazette" estimates the produce of 1871 at 5,000,000; others place it as high as 7,000,000 or 8,000,000. The aggregate value of the vintage of California, including \$400,000 as the cash value of grapes marketed for other purposes than wine making, may be put down at \$2,500,000. The kinds of wines produced in California are as follows: 1. *White Wines*. The California Hock is of a bright straw color, somewhat variable in bouquet and quality, according to the place of growth, varieties of grapes used, and the skill of the producer; but it is generally far stronger, more fiery and apt to intoxicate the unwary than the Rhine wine. It is smoother, but has little of the exquisite bouquet of the Rhine wines, and their enlivening and exhilarating qualities. Of all the wines of California, this is most consumed in the Atlantic states, and is sometimes sold as Rhine wine. The Port, principally raised in Los Angeles, is dark red, strong and sweet, very probably made so by the addition of sugar and alcohol, like its European namesake. Angelica is a sweet wine, a favorite among ladies. It is not a pure wine, as alcohol, distilled from grapes, is added to it, and it is therefore a much stronger wine than many suppose. Madeira, sherry, muscatel, and claret are all made, but only in smaller quantities, and not highly esteemed. 2. *Sparkling Wines*. The brothers Sansevain first undertook to make sparkling wines in 1837, but without success. They and some others who turned their attention to the subject suffered great loss in numerous experiments, which resulted at last, however, in making a good sparkling wine from the grapes of California. The Buena Vista company have pursued this enterprise with great success since 1863, and Isidor Landsberger and company prepare monthly between 800 and 1,000 bottles. It is rather too heavy in body, however, and lacks the sprightliness and ethereal qualities of the best imported French and German sparkling wines, as also of the sparkling Catawbas, Concorde, and other varieties made in the Atlantic

states. The prices of the California wines fluctuate a good deal, but it is perhaps the only country where wine at its place of production is cheaper than milk. In August, 1869, a gallon of ordinary wine brought 30 cts. at Anaheim and Los Angeles, while a gallon of milk cost 50 cts. —The wines of New Mexico resemble those of California very much in character, but are rarely in the market. This may partly be accounted for by the isolated position and inaccessibility of the country, partly by the indolence of the manufacturers. During the last few years grape culture has attracted a good deal of attention in Oregon, and it seems both native and foreign varieties thrive there equally well.—It is difficult to give even an approximate statement of the amount of the wine interest in the United States. There are hardly any trustworthy statistics to be gathered, as the manufacture is spread over so vast a territory, of which many portions are yet but thinly inhabited. The following statistics are mostly derived from private sources, and should only be taken as approximate :

	Gallons.		Gallons.
California.....	5,000,000	Wisconsin.....	25,000
Ohio.....	3,500,000	Maryland.....	25,000
New York.....	3,000,000	South Carolina.....	25,000
Missouri.....	2,500,000	Alabama.....	20,000
Illinois.....	2,500,000	Connecticut.....	20,000
Pennsylvania.....	2,000,000	Mississippi.....	15,000
Iowa.....	400,000	Tennessee.....	15,000
Kentucky.....	300,000	Arkansas.....	15,000
Kansas.....	200,000	Georgia.....	15,000
Indiana.....	150,000	Louisiana.....	10,000
North Carolina.....	40,000	Delaware.....	5,000
Michigan.....	40,000	Dist. of Columbia...	5,000
West Virginia.....	35,000	Massachusetts.....	5,000
Virginia.....	30,000	Nebraska.....	5,000
Texas.....	30,000	Oregon.....	5,000
New Mexico.....	30,000	Washington Ter.....	5,000
New Jersey.....	25,000	Other States and Ter.	5,000
Total.....			20,000,000

Of this amount 5,040,000 gallons would come from the Pacific and 14,060,000, from the Atlantic coast. The varieties of the Atlantic states, and their approximate value from the producer to the dealer, may be estimated as follows:

	Gallons.	Price.	Value.
Catawba.....	6,000,000	\$0 75	\$4,500,000
Concord.....	4,000,000	0 50	2,000,000
Norton's Virginia.....	1,000,000	1 00	1,000,000
Delaware.....	1,000,000	1 25	1,250,000
Clinton.....	1,000,000	0 75	750,000
Isabella.....	1,000,000	0 50	250,000
Ives.....	500,000	0 75	375,000
Herbmont.....	250,000	1 25	312,500
Scuppermong.....	100,000	1 00	100,000
Other varieties.....	610,000	1 00	610,000
Total.....	14,060,000		\$11,147,500

To this may be added:
 For grapes consumed.....\$5,000,000
 For grape vines and grape wood.....5,000,000
 For brandy distilled from grapes, husks, and lees... 1,900,000
 Total product of vineyards of the Atlantic States.. \$22,147,500

If the fact is taken into account that grape culture has really assumed importance only within the last 10 years, it may safely be predicted that it will be trebled within the next 25 years, and become a vast source of national wealth.

AMERIGO VESPUCCI. See **VESPUCCI.**

AMERSFOORT, a town of the Netherlands, in the province of Utrecht, with a port on the river Eem, about 10 m. from its mouth in the Zuyder-Zee, and 12 m. E. N. E. of Utrecht; pop. in 1867, 13,258, nearly half Roman Catholics. It has manufactories of cotton and woolen stuffs, an industrial school, a Latin school, and a Jansenist seminary. Corn and tobacco are cultivated very extensively in the vicinity, and a brisk trade is carried on.

AMES, Edward R., D. D., an American clergyman, bishop of the Methodist Episcopal church, born at Amesville, Ohio, May 20, 1806. In 1826 he entered the Ohio university at Athens, and in 1828 opened a high school at Lebanon, Ill., which was the germ of McKendree college. After remaining here until 1830, he entered the itinerant ministry as a member of the Indiana conference. Being one of the delegates to the general conference of 1840, he was elected corresponding secretary of the missionary society for the south and west. From 1844 to 1852 he was a presiding elder in the Indiana conference, and was then elected bishop. He was the first Methodist bishop to visit the Pacific coast. During the civil war he served on several important commissions. Since 1861 he has resided in Baltimore.

AMES, Fisher, an American orator, statesman, and political writer, born in Dedham, Mass., April 9, 1758, died there, July 4, 1808. His father, who was a physician, died when the son was but 6 years old, but his loss was in some degree supplied by the energy and good sense of his widow. Fisher graduated at Harvard college at the age of 16. His youth, the disturbed state of public affairs, and the narrowness of the family means, delayed for several years his entrance into the profession of the law. During this interval, however, he was busily educating himself by the study of the Latin and English classics. In 1781 he was admitted to the bar, and began practice in his native town. But it was his political essays in the Boston newspapers, under the signatures of Brutus and Camillus, that first made his abilities generally known. When their authorship was discovered, he entered into private and political intimacy with the leading men of his own state and elsewhere, who were afterward the prominent federalists of the Washington school. He was a member of the Massachusetts convention assembled in 1788 for ratifying the federal constitution, and made himself conspicuous by the zeal and eloquence with which he recommended its adoption. When the federal government went into operation, Mr. Ames was elected the first representative of his district, which then included Boston, in congress, and kept his seat during the eight years of Washington's administration. His readiness in debate and the splendor of his set speeches place him in the very first rank of parliamentary orators. At the close of his speech advocating the ap-

propriation required for the execution of Jay's treaty with Great Britain, a member of the opposite party moved an adjournment, on the ground that the house was not in a state of mind to dwell calmly on the question when fresh from the excitement of its eloquence. At the close of his fourth term Mr. Ames left congress and returned to his profession. His interest in public affairs at that most excited period was manifested by fresh essays in the newspapers; but he took no immediate part in politics and accepted no office, excepting that of executive councillor under the administration of Governor Sumner. On the death of Washington he pronounced his eulogy before the legislature of Massachusetts. The gradual failure of his health compelled him soon to withdraw from the active practice of his profession, and he spent the last years of his life in philosophic retirement. He was married in 1792 to Frances, daughter of John Worthington of Springfield, and in the occupations of domestic life, the superintendence of his farm and orchards, the study of literature, and the society of a brilliant circle of friends, his life wore away peacefully and happily. The chief drawback to his satisfaction was found in the gloomy forebodings as to the future of his country and the success of the experiment of republican government, which he felt in common with most of his school of politics. His works were collected and published in one volume soon after his death, with a memoir written by the Rev. John Thornton Kirkland. An enlarged edition, in two volumes, appeared in 1854, edited by his son, Mr. Seth Ames, of Cambridge, Mass. The first volume of this edition is composed of his letters, and they add to his former reputation that of one of the liveliest, wittiest, and most graceful of letter-writers. His orations, essays, and letters are of the highest excellence in their several departments, although the exuberance of his imagination, displayed in the multitude and splendor of his metaphors and illustrations, is sometimes perhaps a little excessive, notwithstanding their felicity and appositeness. His appearance was attractive, his manners gentle and prepossessing, the play of his wit and imagination brilliant and incessant. Many of his *bons mots* have passed into proverbs.

AMES, Joseph, an American portrait painter, born in Rosebury, N. H., about 1825, died Oct. 30, 1872. He practised his art many years in Boston. Among his chief works are portraits of Pius IX., Rachel, Daniel Webster, Rufus Choate, and President Felton of Harvard college. His "Death of Webster," a large composition containing a number of figures, has been engraved.

AMES, Joseph, an English antiquary, born in Yarmouth, Jan. 23, 1689, died Oct. 7, 1759. He was a ship chandler or an ironmonger in Wapping, London, and wrote a work entitled "Typographical Antiquities, being an Historical Account of Printing in England, with some Memoirs of our Ancient Printers." It was a

valuable compilation, and made more so by the subsequent additions of Herbert and Dr. Dibdin. He was the author of some other antiquarian works, was a fellow of the royal society, and secretary of the antiquarian society from 1741 till his death.

AMES, William, D. D., an English Independent divine, born in Norfolk county in 1576, died in Rotterdam in November, 1633. He was educated at Christ's college, Cambridge, of which he became a fellow. In the reign of James I. he left the university in order to avoid expulsion for nonconformity, and retired to the Hague, where he became minister of an English church. Subsequently he filled for twelve years the chair of divinity of the university of Francker. He then removed to Rotterdam, and intended to emigrate to New England, but this design was frustrated by his death. His widow and children, however, did sail for America. He left many controversial writings against the Arminians and others, and his *Medulla Theologia* was famous in its day.

AMESBURY, a town of Essex county, Mass., about 40 m. N. of Boston, and 6 m. N. W. of Newburyport, extending from the N. bank of the Merrimack river to the New Hampshire line; pop. in 1870, 5,581. A branch of the Eastern railroad extends from Salisbury to this point. Manufacturing is extensively pursued. The town contains 5 woollen mills, with 46 sets of machinery, using annually \$1,257,500 worth of stock, and employing 270 males and 372 females; 1 brickyard, 2 manufactories of hats and caps, 18 of carriages, 1 of carriage wheels, 3 of harnesses, 3 saw mills, and 21 blacksmith shops. There are several churches, good schools, and a weekly newspaper. It is the home of the poet John G. Whittier, who is frequently called the bard of Amesbury. Josiah Bartlett, M. D., one of the signers of the declaration of independence, was born here in 1729.

AMETHYST (Gr. ἀμέθυστος, preventing intoxication, so named because it was supposed by the ancient Persians that cups made of it would prevent the liquor they contained from intoxicating), a stone consisting of crystallized quartz of a purple or bluish violet color, probably derived from a very small amount of oxide of manganese or, according to Heintz, from a compound of iron and soda. The color is not always uniformly diffused through it, and is less brilliant by candlelight. The name was used by the ancients for several other minerals, which had a color similar to the amethyst. In mineralogy, amethyst is that variety of quartz that exhibits a wrinkled fracture, instead of the usual conchoidal one.—For oriental amethyst, see SAPPHIRE.

AMGA, a river in Siberia, which rises in the Yablonny mountain range, flows in a N. N. E. direction nearly 460 m., and falls into the Aldan, the principal eastern affluent of the Lena. At its passage through the village of Amginsk, where it is bounded on each side by steep rocks up-

ward of 30 feet in height, it attains a breadth of 3,000 feet.

AMHARIC LANGUAGE, the language of Amhara, the largest division of Abyssinia, including all that portion which lies between the Blue Nile and the Tacazze rivers, and having Lake Tzana in the centre. It is spoken with some variations of dialect throughout Abyssinia, and a knowledge of it is therefore essential to an Abyssinian traveller. It is of ancient Semitic origin, and related to the old Ethiopian or Geez, which it superseded in the early part of the 14th century as the language of the court, and gradually also as the popular idiom. It resembles, however, the Geez much less than does the Tigré, the dialect of the northern province of Abyssinia, being to a great degree corrupted by non-Semitic African admixtures, and stunted in its grammatical forms. Its alphabet is the Geez, slightly modified. (See ETHIOPIAN LANGUAGE.) Very little is known of the Amharic language, though the British and Foreign Bible society have published first the New Testament (1829) and later the whole Bible in that tongue.

AMHERST, a W. central county of Virginia, bounded S. E. and S. W. by the James river, and N. W. by the Blue Ridge; area, 418 sq. m.; pop. in 1870, 14,900, of whom 6,704 were colored. It abounds in fine scenery, of which the passage of the James river through the Blue Ridge is specially noted. Its soil is fertile, and largely covered with forests and plantations. The productions in 1870 were 75,065 bushels of wheat, 160,655 of corn, 117,608 of oats, 1,285,471 lbs. of tobacco, and 109,773 of butter. The Virginia and Tennessee railroad passes through the county. Capital, Amherst Court House.

AMHERST, a town of Hampshire county, Mass., 82 m. W. of Boston, on a branch of the Connecticut river; pop. in 1870, 4,035. The situation of the town affords extensive views of the Connecticut valley and adjacent mountain ranges. It contains 5 Congregational churches, 1 Baptist, and 1 Episcopal. The preparatory high school is considered one of the best in the state. There are 4 paper mills, an establishment for the preparation of palm leaf for hats, bonnets, &c., and one for their manufacture. A weekly newspaper, and a semi-monthly periodical are published in the town. The Massachusetts agricultural college, with its extensive dormitories and greenhouses, is about a mile N. of the town, and possesses with other objects of interest the Durfee plant house, which is well stocked with rare and beautiful plants. Since its opening in 1866 this institution has become the largest and most successful agricultural school in the country. Amherst college, one of the chief seats of learning in New England, was founded in this town in 1821, under the auspices of the Orthodox Congregationalists. Its projectors had in view the gratuitous education of young men for the ministry, and the charity fund devoted exclusively to this object now amounts to about \$70,000. There

is a large number of scholarships available to needy students, and no earnest young man is allowed to leave for want of money. This fund now amounts to \$100,000. The Rev. Zephaniah Swift Moore was the first president of the college. He died in 1823, and was succeeded by the Rev. Heman Humphrey, who retained the office till 1845, and performed important services to the institution, having safely carried it through the most perplexing embarrassments. The Rev. Edward Hitchcock followed him, and resigned in 1854, when the present incumbent, the Rev. William A. Stearns, D. D., LL. D., was inaugurated. The managers of the institution had to struggle against many discouragements at the outset, and not a dollar was appropriated in its aid from the state treasury during the first 25 years of its existence. The state appropriations to the present time amount to \$52,500, a portion of which was for the endowment of the "Massachusetts Professorship of Natural History." The college has received many munificent donations from individuals. Dr. William J. Walker, a resident of Charlestown, Mass., and a graduate of Harvard college, besides giving to the institution during the latter years of his life upward of \$90,000 toward the erection of a building for scientific purposes, and founding a professorship of mathematics and astronomy, left a legacy for similar purposes of nearly \$150,000. The next largest giver is Samuel A. Hitchcock of Brimfield, who has contributed to the college \$175,000. The donations of the Hon. Samuel Williston, an eminent manufacturer in Easthampton, Mass., who has long been one of the most ardent friends of the institution, amount to about \$150,000. The funds for the college church recently erected were given by W. F. Stearns, son of the president of the college. Amherst college has 12 public buildings besides the president's house, including an edifice for scientific and other purposes recently built at the cost of more than \$120,000, and a church for such as do not prefer to worship with other denominations. In the tower is a chime of bells, presented by the late George Howe of Boston, and beneath it a small room for tablets in commemoration of the young men who fell in the war. A gallery of art has been started. In 1847 a handsome edifice was erected to be employed as a cabinet of natural history and an astronomical observatory, chiefly by the efforts of the Hon. J. B. Woods of Enfield. The library, a fine building, was constructed in 1853, of Pelham granite. The college possesses a valuable philosophical and astronomical apparatus, an extensive geological and conchological museum, collections of meteorites and geological specimens, a Nineveh gallery containing about 200 specimens from the ruins of ancient Nineveh and Babylon, a museum of Indian relics, and the Hitchcock technological collection. In this unique cabinet, named after the late President Hitchcock, are to be found about 1,400 specimens, containing at least 20,000

tracks of animals in stone, together with plaster and clay casts of tracks of living and fossil animals. There is in the curriculum a regular department of physical training, under the care of a physician. There are 13 professors and 8 lecturers and instructors. The libraries of the college and various literary societies contain about 36,000 volumes. The number of under graduates is 244. In 1869 the whole number of graduates was 1,829, of whom 1,449 survived. Of the whole number, 751 became clergymen, 75 missionaries, 129 physicians, 186 lawyers, and 208 teachers.

AMHERST, a town of British Burmah, in lat. 16° 5' N., lon. 97° 25' E., on a triangular peninsula N. E. of the gulf of Martaban, 30 m. S. of Maulmain; pop. increased from 5,000 in 1838 to 20,000 in 1853, but since largely reduced. It was founded by the English in 1826, and rapidly increased in population and prosperity, but has been superseded by Maulmain, of which it now constitutes an outer port and a station for pilots. The harbor is spacious and secure, but the bar across its entrance is dangerous. The military cantonments are on an elevation 1½ m. outside of the town. It is a resort of invalids from Maulmain, owing to its salubrious climate.

AMHERST, **J. Jeffery**, baron, an English general, born in Kent, Jan. 29, 1717, died Aug. 3, 1797. He entered the army at the age of 14, was present at Dettingen and Fontenoy on the staff of Gen. Ligonier, and in 1758 was sent to America with the rank of major general. In conjunction with Wolfe and Prideaux, he made the entire conquest of the French strongholds in Canada, for which he received the thanks of the house of commons and the order of the Bath. He was soon afterward appointed commander-in-chief of the British forces in America. In 1763 he was appointed governor of Virginia, and in 1770 governor of the island of Guernsey. He was commander-in-chief of the army 1772-'82, and again 1793-'5, when he was superseded by the duke of York, and was soon afterward made a field marshal. In 1776 he was elevated to the peerage, with the title of Baron Amherst of Holmesdale; and in 1787 he received a patent as Baron Amherst of Montreal. **II. William Pitt**, earl, and Viscount Holmesdale, a British statesman, nephew of the preceding, born Jan. 14, 1773, died March 13, 1857. He was British ambassador in China, and succeeded Hastings as governor general of India (1823-'7). Under his administration the Burman war resulted in an important accession of British territory, and his services were rewarded with an earldom in 1826.

AMIANTHUS. See **ASBESTUS**.

AMICE, or **Amict** (Lat. *amicus*, girt around), a vestment worn by priests in the Roman Catholic church during the celebration of mass. It consists of a square linen cloth tied over the neck and shoulders, and was originally used as a protection for the throat. After the general adoption of the cravat had rendered the amice

unnecessary as a neckcloth, it was retained for the significance which it had acquired as an emblem of the cloth wherewith the Saviour was blindfolded by the Jews the night before his crucifixion.

AMICI, Giovanni Battista, an Italian optician and astronomer, born in Modena, March 25, 1784, died in Florence, April 10, 1863. He became eminent at an early age for his mathematical and general scientific attainments, and directed for upward of 30 years the Florence observatory. He also lectured on astronomy, and was a member of almost all the learned academies of Europe. Science is especially indebted to him for his improvement of the telescope, of several microscopes, and of the camera lucida, invented by Hooke and Wollaston. In 1827 he made dioptric microscopes, which are sold with his name attached, and, notwithstanding the improved microscopes of Oberhäuser, are still in great favor. He was assisted in his labors by his son VINCENZO, who is professor of mathematics at the university of Pisa.

AMIDAS, Philip, an English discoverer, born in Hull in 1550, of a Breton family, members of which had been for nearly a generation domesticated in England, died about 1618. He commanded one of the two ships composing the first expedition sent by Queen Elizabeth under Arthur Barlow to North America. They touched at the Canaries, the West Indies, and Florida, and then made their way northward along the coast. On July 13, 1584, they entered Ocracoke inlet, and landed on Wocoken island. Barren and desolate as this part of North Carolina now is, the mariner thought it beautiful, and gave gorgeous descriptions of it. The people of the country were kind and gentle, and the scenery was lovely and luxuriant. On the return of Amidas and Barlow to England they reported their discoveries to Raleigh, who does not appear ever to have been on the North American continent, and from him the matter was imparted to Queen Elizabeth, who called the new land "Virginia." Amidas was long after in the English maritime service, and went in charge of an expedition to Newfoundland a few years later. He died in England a few months before Raleigh's execution.

AMIENS, a town of France, capital of the department of Somme, 70 m. N. of Paris, on the Somme, which is navigable for small craft; pop. in 1866, 61,063. The old ramparts have been converted into fine boulevards and promenades. The citadel is the only remnant of the former fortifications. Of the ancient castle nothing remains but the crypt, which is associated with the tradition of St. Firmin's martyrdom. The cathedral, one of the largest and finest Gothic edifices in Europe, is remarkable for the splendor of its interior. Amiens has an academy, a lyceum, and a public library. In the place St. Michel is a statue of Peter the Hermit, who was born here. Amiens has been the centre of the French cotton industry since the last century. The cotton velvet fac-

tories employ 400 looms, and the other manufactories over 3,000. The annual consumption of wool is estimated at 100,000,000 lbs.—Amiens was the Samarobriva of the Romans, the present name being traced to the Ambiani, the early Gallic inhabitants. In the middle ages it was the centre of a district then called the Amiénois, and ruled by bishops of the town. At the end of the 12th century it was united to the French crown. Subsequently it was ruled by the dukes of Burgundy, but it reverted to the crown under Louis XI. The Spaniards, who captured Amiens in 1597, were speedily dislodged by Henry IV. with the aid of English troops. The treaty of Amiens, establishing peace between England, France, Spain, and the Batavian republic, was signed in 1802. During the Franco-German war the town was occupied for some time by the Germans, after a decisive victory won over the French in the vicinity, Nov. 27, 1870.

AMIOT, or Amyot, Joseph, a French Jesuit and missionary to China, born in Toulon in 1718, died in Peking in 1794. He was early distinguished for great scientific attainments and indefatigable industry. In 1750 he was sent to China, and after some stay at Macao was called by the emperor Kien-lung to Peking, which he reached Aug. 22, 1751, and never afterward left. Devoting himself to the study of the antiquities, history, languages, and arts of the Chinese and Manchus, he annually sent to France memoirs, treatises, and translations which greatly extended European knowledge on these subjects. Among his works published separately were: *Eloge de la ville de Moukden*, a translation of a poem by the emperor Kien-lung, with numerous notes (1770); *Art militaire des Chinois* (translation, 1772); and *Dictionnaire tatar-manchou-français* (3 vols. 4to, 1789), which was edited by Langlès, and the types for which were cut and cast at the expense of the minister Bertin. But the greater part of his writings were included in the *Mémoires concernant l'histoire, les sciences et les arts des Chinois* (15 vols. 4to). The list of his contributions to the first 10 volumes of this work occupies 14 columns of the table of contents. His treatise on Chinese music fills most of vol. iv., and his life of Confucius nearly all of vol. xiii. In vol. xiii. there is a brief Manchoo grammar by him.

AMITE, a river rising in S. W. Mississippi, passes into Louisiana, and reaches Ascension parish by a southerly course; it then turns and flows S. E. and E. to Lake Maurepas. It is navigable by small steamboats for a distance of 60 miles.

AMITE, a S. W. county of Mississippi, bordering on Louisiana, named from the Amite river, which flows through its centre, and bounded on the N. W. corner by the river Homochito; pop. in 1870, 10,973, of whom 6,777 were colored. The area was 700 sq. m., but a portion of its territory was taken in 1870 to form the new county of Lincoln. The county is mainly oc-

cupied by cotton fields and forests; its surface is somewhat uneven. The soil is fertile. The productions in 1870 were 254,784 bushels of corn, 53,702 of sweet potatoes, 11,233 lbs. of rice, and 17,456 bales of cotton. Capital, Liberty.

AMLWCH, a seaport town on the N. shore of the island of Anglesea, Wales, the terminus of the Chester and Holyhead railway; pop. in 1861, 5,949. The celebrated Parys copper mines, in its vicinity, which gave the town importance, have of late years greatly decreased in productiveness.

AMMAN. **I. Johann Konrad**, a Swiss physician, born at Schaffhausen in 1669, died at Warmond, near Leyden, about 1725. He studied at Basel, but established himself in Holland. In 1692 he published an essay entitled *Surdus Loquens* ("The Deaf Speaking"), in which he gave an account of the results of his successful efforts in teaching a girl deaf and dumb from birth to articulate. In 1700 he published another essay entitled *Dissertatio de Loquela*. These two works were of great value to Heinicke, Braidwood, and De l'Épée, who at a later period organized schools for the instruction of deaf mutes. He was also noted as an editor and translator of the classics. **II. Jost**, or **Jodocus**, a Swiss painter and engraver, born in Zürich in 1539, died in 1591. In 1560 he established himself at Nuremberg, where he acquired fame, especially by his woodcut illustrations of *Reineke Fuchs*, Luther's Bible, Schopen's *Panoplia*, and many other works, being the best and most prolific illustrator of his time. His paintings are rare and much sought for.

AMMIANUS MARCELLINUS, a Roman soldier and historian, born in Antioch, of a Greek family, died about A. D. 395. In his youth he embraced the military profession, and served under Ursicinus, one of the most celebrated of the generals of Constantius. In 363 he accompanied the emperor Julian in his expedition against the Persians. He ultimately settled at Rome, and devoted his latter days to the composition of his history of the emperors from the accession of Nerva, A. D. 96, to the death of Valens in 378. It comprised 31 books, the first 13 of which are lost. The style is vicious and inflated, but the work is highly valuable as an authority.

AMMERGAU. See OBER-AMMERGAU.

AMMON, a deity extensively worshipped in ancient times in many countries of Africa and Europe. The Egyptians called him Amen or Amen-Ra (Ammon the Sun), the Hebrews Amon, the Greeks Zeus Ammon, and the Romans Jupiter Ammon. His most celebrated temples were at Thebes in Upper Egypt, in the Libyan oasis of Ammonium (now Siwah), and at Dodona in Greece. He was generally represented in the form of a ram, or as a human being with the head of a ram. This representation meant probably that Ammon stood in the same relation to men as the ram does to the flock; that he was the guide, governor, and

protector of the people. The derivations of the name Amen are numerous, but none has as yet obtained general acceptance.

AMMON, **Christoph Friedrich von**, a German Protestant theologian and pulpit orator, born in Baireuth, Jan. 16, 1766, died in Dresden, May 21, 1850. He studied theology in Erlangen, in 1789 became professor of philosophy, and in 1792 professor of theology and preacher at that university. From 1794 to 1804 he was professor of the same branches in Göttingen, then until 1813 again in Erlangen, and from that time until his death Protestant court preacher, vice president of the consistory, and afterward member of the ministry of worship in Dresden. In 1825 he accepted the old title of nobility, which his family had lost in 1640, together with their feudal estates, on account of their fidelity to Protestantism, and which the king of Bavaria had in 1824 restored to them. Ammon was, together with Bretschneider, Paulus, Röhr, and other German theologians of minor rank, the father of what is known as German theological rationalism. In his principal work, "Development of Christianity into the Universal Religion" (*Fortbildung des Christenthums zur Weltreligion*, 4 vols., Leipsic, 1833-'40), he holds that the Christian religion is perfectible not only in its external form as a church, but also in its substance and nature, and must be further developed if it is to embrace the whole of humanity. He regards Jesus as a mere man, who attained the highest scope and elevation, and so became intimately united with God. Though he was among the first to introduce the Kantian philosophy into theology, and to lay a great stress on the use of reason in matters of revealed religion, he was no systematic and comprehensive thinker. Nice distinctions being at that time drawn among the rationalists between rational supernaturalism and supernatural rationalism, he called himself a follower of the latter school, according to which belief or faith begins where science ends, and revelation may make up for the deficiencies of reason. This position being too much exposed to objections from the side both of believers and unbelievers, he was sometimes, as for instance by Schleiermacher in the dispute on "Harms's Theses," charged with duplicity; and his last great work, "The Life of Jesus" (2 vols., Leipsic, 1842-'4), was even ridiculed on account of its undecided position in regard to the later critical theories of Strauss, Bruno Bauer, Feuerbach, and the Tübingen school. Among his other writings we may mention particularly *Handbuch der christlichen Sittenlehre* (3 vols., Leipsic, 1823; 2d ed., 1838); *Anleitung zur Kanzelberedsamkeit* (3d ed., Erlangen, 1826), more naturalistic in the 1st and 3d, more supernaturalistic in the 2d edition; *Entwurf einer reinbiblischen Theologie* (2d ed., 3 vols., Göttingen, 1801-'2); *Summa Theologia Christiana* (4th ed., Leipsic, 1830); and his last work, *Die wahre und falsche Orthodoxie* (Leipsic, 1849). He had the misfortune to see

the theological system which he represented entirely deserted by the great mass of his contemporaries, either for infidelity or for thoroughgoing orthodoxy and pietism. His biography is entitled *Ch. F. Ammon nach Leben, Ansichten und Wirken* (Leipsic, 1850).

AMMONIA, volatile alkali. The origin of the word is uncertain; some authors suppose it to be from the god Ammon, near whose temple in Upper Egypt it was produced; others from Ammonia, a Cyrenaic territory; while others again derive the word from *ἀμμος*, sand, because the sal ammoniac (*τὸ ἀμμονιαχόν*) was found in the sands of Africa. Pliny was probably acquainted with it; it was afterward discovered in 1677 by Kunckel, still later in 1756 by Dr. Black, and finally more fully described by Dr. Priestley in 1774. It is composed of one volume of nitrogen and three volumes of hydrogen, which on combination condense to two volumes. In its pure state, and at the ordinary temperature and pressure, it is a colorless, pungent gas, wholly irrespirable, not a supporter of combustion, excepting of bodies which readily combine with hydrogen, strongly alkaline, having a specific gravity of 0.59, and readily converted into a liquid by cold or pressure. The elastic force of the vapor of liquid ammonia at different temperatures, according to Bunsen, is as follows: at $-33.7^{\circ}\text{C.} = 1$ atmosphere; at $-5^{\circ}\text{C.} = 4$ atmospheres; at $0^{\circ}\text{C.} = 4.8$; at $+5^{\circ}\text{C.} = 5.6$; at $+10^{\circ}\text{C.} = 6.5$; at $+15^{\circ}\text{C.} = 7.6$; at $+20^{\circ}\text{C.} = 8.8$. Bunsen prepared the liquefied ammonia by causing the perfectly dry gas to pass through a column of hydrate of potash, and thence into a tube cooled to -40°C. The liquid ammonia is colorless, very mobile, having a specific gravity of 0.63. It freezes under a pressure of 20 atmospheres at -75°C. , and at -87°C. in vacuo. This solid, frozen ammonia is a white, transparent, and crystalline body, possessed of a faint odor. Liquid ammonia is a powerful solvent for a number of metals, as has been recently (1871) shown by Professor Charles A. Seely of New York. Two important applications of liquid ammonia have been made in modern times. The first is its employment as a motive power according to the invention of a French chemist, M. Tellier; and the second is the invention of M. Carré to use it for the artificial production of cold. One gramme of water at 0°C. and 760 mm. pressure absorbs 0.877 gramme or 1,149 times its volume of ammonia gas; at 20°C. it absorbs 681 times its volume and yields the liquid ammonia of the shops.—Commercial ammonia was formerly obtained from the sal ammoniac of Africa; but this source is entirely inadequate to supply the present demand, and recourse has been had to numerous other sources. The greater part of the aqua ammoniac of the shops is derived from the waste liquors of the manufactories of illuminating gas. The ammonia of the boracic acid works of Italy is also saved, and some establishments yield 3,300 lbs. of sulphate of ammonia every 24 hours, in addition to the boracic acid which

is condensed in the water. Some of the crude crystals of borax contain nearly 4 per cent. of ammonia, and when these are fused with soda, the ammonia is driven out and can be condensed in suitable vessels. When caustic soda is mixed with Chili saltpetre, much ammonia is liberated, which can be condensed and saved. The ammonia arising from the beet in the manufacture of sugar and from the gas in coking furnaces is also economized to some extent. The preparation of ammonia for the arts is founded upon the action of quicklime upon a convenient ammoniacal salt. It is customary to distil an intimate mixture of one part of pulverized sal ammoniac with two parts of moistened lime, and to condense the gas in water. On a large scale ammonia is obtained directly from gas-house liquors, without being previously converted into sal ammoniac.—Ammonia is produced in the juices of various nitrogenous animal and vegetable substances in their putrefactive fermentation. It is given out in their decay, and, passing into the atmosphere, is condensed by the aqueous vapor, and returned to the earth in rain water, mists, and snow. It furnishes to plants the nitrogen they require, and is thus the principal valuable ingredient of the manures. Guano is a great repository of it. The shavings of horn have been used to prepare it, whence the name spirits of harts-horn. It is given out in the destructive distillation of all bituminous mineral matters, coming over in an impure state, condensed in the aqueous vapors, and mixed with the tarry products. This is the source from which it is now principally obtained for commercial purposes. It is also evolved from urine in a state of decomposition; and from this substance are prepared annually in Paris from 17,000 to 18,000 lbs. of ammoniacal salts. Refuse animal substances, as bones and horns, blood and hair, horse flesh, and rags of wool and silk, are made to yield a variety of ammoniacal salts—as the carbonate and acetate—by distilling them. The chief product is the subcarbonate of ammonia in solution. From the solid matters that will not distil over are obtained animal black, which is used for clarifying sugars, and a carbonaceous substance employed in the manufacture of Prussian blue. Sal ammoniac is prepared from the crude carbonate thus obtained in combination with the ammoniacal products of the gas works and other operations referred to. The liquors are saturated with muriatic acid and evaporated; the salt deposited is dried and then sublimed, by which means it is collected free from impurities. Ammonia yields numerous salts, some of which are employed in the arts. They are all readily destroyed by heat.—The water of ammonia, the carbonate, chloride, and acetate, are used in medicine; the first externally as an irritant or to develop the gas; the others internally. Their effect is to temporarily accelerate the heart's movements, by an action rather on the muscular than on the nervous appa-

ratus, and to liquefy mucus where they come in contact with it, either directly as in the stomach and intestines, or in the way of elimination, as in the bronchial tubes. It leaves the system by the lungs, skin, and kidneys, having much less effect than the fixed alkalis in alkalizing the secretion of the latter organ. Carbonate of ammonia is used as a rapidly diffusible stimulant in various diseases, especially febrile and neuralgic, and sometimes as an expectorant, its action being twofold, strengthening the bronchial muscles and liquefying the mucus. The chloride, though it is less powerful as a stimulant, is used for similar purposes, and also in some affections of the digestive organs. The *liquor ammoniac acetatis* or *spiritus Mindereri* is, in the doses usually given, but little more than a placebo. Ammonia, in the gaseous or liquid form, has been proposed as an antidote to several poisons, especially alcohol, carbonic acid, and prussic acid. For these purposes the stimulant action is desired, but the gas must be used with great caution on account of its irritant effect on the air passages. The injection of ammonia into the veins, as a cure for the bite of venomous serpents, has been practised by Prof. Halford of Australia, and others on his recommendation. Although recoveries have been reported, the question of its efficacy must be regarded as still unsettled.

AMMONIAC, the concrete juice of *dorema ammoniacum*, an umbelliferous plant, a native of Persia. It occurs in masses of a brownish color containing opaque, yellowish, homogeneous tears, or the same tears may be found separated. It is a gum resin with volatile oil. It has been used in medicine as an expectorant and so-called antispasmodic. In the form of a plaster it is used externally. It is allied therapeutically as well as botanically and chemically to asafetida.

AMMONITES, a genus of fossil shells allied to the *nautilus*. The fossils are in the form of a coil or of a ram's horn, and the name is given to them from their resemblance to the horns upon

Ammonites Jason.

the statues of Jupiter Ammon. They also resemble a snake in its coil, and are generally supposed by the common people to be petrified snakes. The animal that inhabited the shell was provided with air chambers, by means of which it could rise or sink in the water; and its shelly covering, necessarily very delicate in order to float, was made strong to bear the pressure at

great depths by its tubular form and by the ribs or plates of shell that supported it within. From the lower rocks of the transition period up to the tertiary, the ammonite has been represented by many species. They abound especially in the oolite. They appear to have been

Ammonites Nodotianus.

very widely distributed over the ancient seas, the same fossil species being found in rocks of the same period in different quarters of the globe. They are common in the greensand

Ammonites Cordiformis.

formation in New Jersey, and far up the Missouri river. In Asia, at an elevation of 16,000 feet, in the Himalaya mountains, some of the same species have been found that are met

Ammonites Tornatus.

with in England, and one of the same in the Maritime Alps, 9,000 feet above the sea. They are so abundant in some parts of Burgundy that the roads are paved with them. In the chalk formation they are found of gigantic size, three and even four feet in diameter.

AMMONIUM, the hypothetical radical of ammonia, supposed to be metallic. What is called an amalgam of mercury and ammonium was first obtained by Berzelius and Pontin from the

aqueous solution of ammonia. Davy produced it with sal ammoniac; and it has since been obtained by simply dropping an amalgam of sodium and mercury into a strong solution of sal ammoniac. At a temperature of 32° F. it is a firm crystalline mass; at 70° to 80° it is a soft solid. It is about three times the density of water. Gay-Lussac and Thénard consider it a mere combination of mercury and ammonia; but Berzelius regards it as a real amalgam of mercury with a metal composed of one volume of nitrogen and four volumes of hydrogen. Since the discovery of other compound radicals that are capable of neutralizing acids, the question of the metallic character of ammonium has lost its significance, and few chemists are now disposed to insist upon calling it a metal.

AMMONIUM, Oasis of. See SIWAH.

AMMONIUS, a Grecian philosopher, surnamed Saccas or the Sack-carrier, because his official employment was that of public porter of Alexandria, died A. D. 243. By some he is regarded as the founder of the later Platonic school. He numbered among his pupils Longinus, Plotinus, and Origen. According to his system of theological philosophy, God is primarily essence, and secondarily knowledge and power, the last two being developments of the first; the world is committed to the care of inferior divinities; and ascetic life leads to a knowledge of the infinite.

AMMONOOSUCK, Upper and Lower or Great, two small rivers of New Hampshire, tributary to the Connecticut. The former is entirely in Coös county, and empties in the town of Northumberland. The latter rises in Coös county, flows W. and S. W. through Grafton county, and empties opposite Wells River, Vt.; it has a branch called the Wild Ammonoosuck.

AMMUNITION, military stores or provisions for attack or defence. In modern usage, the signification of the term is confined to the articles which are used in charging firearms and ordnance of all kinds, as gunpowder, balls, shot, shells, percussion caps, primers, and cartridges, prepared and ready for use. Small-arm ammunition comprises cartridges and percussion caps, the latter having replaced flints, and in turn been replaced by an arrangement of the fulminate or exploding materials in the base of the metallic cartridges now coming into general use throughout the world. Field artillery ammunition is composed of shot, loaded shell, case shot, shrapnel, cartridges, priming tubes, matches, portfires, &c., with rockets for rocket batteries. In fortresses and for sieges, the powder is generally kept in barrels, and made up in cartridges when required for use; so are the various compositions required during a siege. The proportion of ammunition accompanying an army in the field varies according to circumstances. Generally an infantry or cavalry soldier carries from 40 to 60 rounds, while a similar or larger quantity per man accompanies the army in wagons, or in exceptional cases,

for the use of cavalry, is carried upon pack mules. For field artillery, from 100 to 200 rounds per gun are always kept with the battery, partly in the limber boxes, and partly in separate wagons called caissons. Another 200 rounds are generally with the ammunition reserve of the army, and a third supply follows in wagons, or is kept on hand at depots established at convenient points near the theatre of war. Ammunition for siege and seacoast guns, garrison and naval use, consists mainly of gunpowder, shot, and shell, and is supplied in large quantities proportioned to the probable requirements in each case, the usual practice in time of war being to have from 50 to 150 rounds prepared and ready for use, and the magazines stored with materials for from 600 to 1,000 rounds more. The proportional weights of gunpowder and missiles used in compounding ammunition vary considerably, and are set forth in the manuals and regulations pertaining to that branch of the military service. After a few months of active campaigning, the supplies of ammunition are generally severely drawn upon; and until the introduction of metallic cartridges for small-arms, as much was worn out and rendered useless by the troops while marching as was expended in battle.

AMNESTY (Gr. ἀμνηστία, forgetting, oblivion), an act of oblivion; a general pardon of the offences of subjects against the government, or the proclamation of such pardon. Bouvier, in his Law Dictionary, distinguishes between amnesty and pardon. Amnesty, he says, is an act of the sovereign power, the object of which is to efface and cause to be forgotten a crime or misdemeanor; while pardon is an act of the same authority which exempts the individual on whom it is bestowed from the punishment which the law inflicts for the crime he has committed. Amnesty is the absolution and forgetfulness of the offence; but pardon is pity and forgiveness. Pardon is given to one who is certainly guilty; amnesty to those who may have been guilty. The two things differ further, he says, in their effects and application; and as to the latter distinction, he observes, by way of illustration, that pardon is always given to individuals and after judgment, while amnesty may be granted either before or after judgment, and it is in general given to whole classes of criminals or supposed criminals for the purpose of restoring tranquillity in the state.—But it does not appear, after all, that there is any substantial difference between pardon and amnesty. The act of grace is the same, whether it be expressed in the pardon of an individual or in the amnesty of a class, and though the one be granted after conviction and the other before it. The distinctions which this author suggests seem to relate to the different occasions to which the two acts refer, and to the merely incidental results in either case, rather than to anything different in the essential nature of the acts.—During the late civil war, and since it ended, the presidents of the United States

have issued several proclamations of amnesty to those who participated in it on the rebel side. President Lincoln issued the first of these proclamations on Dec. 8, 1863. President Johnson issued similar proclamations on May 29, 1865, Sept. 7, 1867, July 4, 1868, and Dec. 28, 1868. Some of these proclamations were limited and conditioned, but the later ones were more liberal, and the last named was very broad and unqualified. With especial reference to this last paper, the question was mooted whether the president, in mere virtue of his office, and without the concurrence of congress, had constitutional authority to order a general amnesty; and in a report of the judiciary committee of the senate made in February, 1869, the authority was emphatically denied. The position taken in this report was rested on two grounds; first, that from the time at least when England had a constitution and settled jurisprudence, the crown did not assume to have a power to grant general pardon or amnesty by its mere proclamation, and without the concurrence of parliament, but that such power was regularly and properly exercised only by statute; second, that for hundreds of years there had been a clear distinction in the English law between pardon and amnesty, and that because the constitution used only the former word it must be understood to withhold from the president the power of granting general amnesty. In reference to the power of pardon our constitution is very clear and precise: "The president shall have power to grant reprieves and pardons for offences against the United States, except in cases of impeachment." The question is, under this constitutional provision, what does its word pardon mean? Does it include such a power of offering general amnesty as these proclamations have assumed to give? It is true that, in very many of the instances, though by no means in all, in which general pardons have been granted in England, they have issued in the form of acts of parliament. But even in these the tenor of the statutes, and the proceedings attending their enactment, concede that the act of grace proceeds from the sovereign alone, and not from parliament. Thus in the acts of 25 Charles II., ch. 5 (1673), after the restoration; of 2 William and Mary, ch. 10 (1690), and of 6 and 7 William III., ch. 20 (1694), after the revolution of 1688; of 3 George I., ch. 19 (1717), relating to the insurrection in Scotland in favor of the pretender; and of 20 George II., ch. 52 (1747), after the second rebellion in Scotland, the title of each runs: "An act for the king's (or sovereign's) most gracious, general, and free pardon." The prerogative of the crown in respect to pardon has also always been recognized in the peculiar character of the bill, even when the pardon goes by act of parliament; for, unlike other bills, it is regularly signed by the sovereign before it is introduced into the houses, and it is read but once in either of them; and when it receives the assent of the houses, this is not signified in

the usual form of concurrence, but "the prelates, lords, and commons, in the name of all the sovereign's subjects, most humbly thank his majesty," &c. With regard to the fact that pardons so often issued by statute, it should be remembered that there were usually very substantial reasons for the participation, in a certain sense, by parliament in the sovereign's act of grace, in the fact that a parliamentary act could relieve forfeitures and remove certain other disabilities attending attainers, which a mere pardon could not do; and provisions to this effect were generally introduced into these acts. The fact, therefore, that in any instance a general pardon or amnesty appears to have been granted in the form of an act of parliament, does not of itself imply any denial of the crown's sole prerogative power as to the pardon. More than this, there will be found repeated instances in English history where the sovereign has granted amnesties by general proclamation independently of parliament, and the competency and validity of such acts have never been disputed. In short, so far as the law and practice existed in England before and down to the time of the foundation of our government, it seems to be beyond question that the power of pardon rested finally in the sovereign, and that his grants of general amnesty were conceived to be included in the general power. As to the objection that there was a difference in the English law between amnesty and pardon, it seems to be less sound than the other. Amnesty was never a specific term of the common law, and indeed it rarely occurs even in the statutes; or text books. On the other hand, pardon is a technical term of the law, and is almost exclusively employed. It may be safely admitted that, in allusion to great classes of offenders rather than to individuals, and to the political offences involved in seditions and rebellions in distinction from the more usual crimes, amnesty as a word of description is more apposite and familiar than pardon. But this mere use of language does not reach the core of the thing, and it seems to be beyond dispute that the essential nature and operation of amnesty and of pardon in a legal sense are precisely identical. As to the suggestion that the use of the word pardon in the constitution implies a design to exclude amnesty, it would seem to be completely refuted by the history of the debates upon the constitution. (See Elliott's "Debates," vol. iii., p. 497; vol. v., p. 480.) The discussions there reported show that the very questions of the expediency of reposing the power in the president in cases of political offenders, and it may fairly be said of giving him the power of general amnesty, were expressly debated in the conventions. The 74th number of the "Federalist" is even more conclusive upon these points. Hamilton says there that "the expediency of vesting the power of pardoning in the president has, if I mistake not, been only contested in relation to the

crime of treason. This, it has been urged, ought to have depended upon the assent of one or both of the branches of the legislative body. . . . But there are strong objections to such a plan. It is not to be doubted that a single man of prudence and good sense is better fitted in delicate conjunctures to balance the motives which may plead for and against the remission of the punishments than any numerous body whatever. It deserves particular attention that treason will often be connected with seditions, which embrace a large proportion of the community, as lately happened in Massachusetts [Shays's rebellion]. . . . But the principal argument for reposing the power of pardoning in this case in the chief magistrate is this: In seasons of insurrection or rebellion there are often critical moments when a well timed offer of pardon to the insurgents or rebels may restore the tranquillity of the commonwealth, which, if suffered to pass unimproved, it may never be possible afterward to recall. The dilatory process of convening the legislature or one of its branches for the purpose of obtaining its sanction to the measure, would frequently be the occasion of letting slip the golden opportunity." Before this question about amnesty to rebels arose, or rather before it was made a subject of debate and dispute, the constitutional power of the president as to pardon was construed as embracing all the significance which the word usually had in the English law; and this was large enough to include amnesty in the sense now under consideration. Chief Justice Marshall defined pardon very early as "an act of grace proceeding from the power intrusted with the execution of the law, which exempts the individual on whom it is bestowed from the punishment which the law inflicts for a crime he has committed." Story, in his "Commentaries on the Constitution" (§ 1,509), gives the broadest scope to the power, and indeed he expressly includes in it the power of granting amnesty to rebels, and adopts, without suggesting any doubt of its pertinency and conclusiveness on this head, and as "the chief argument for reposing the power of amnesty in the president," the language on that point above quoted from Hamilton. The early history of the government furnishes significant illustrations of the opinions then prevailing as to the purport of the constitutional grant. In three instances at least within the first quarter of a century after the formation of the government, the president granted general pardons by proclamation without the participation of congress. The first of them was made by Washington, July 10, 1794, in respect to persons who took part in the "whiskey insurrection" in Pennsylvania. By this he granted a full, free, and entire pardon to all persons, with certain exceptions, of all treasons, misprisions of treason, and other indietable offences against the United States. On May 21, 1800, President John Adams proclaimed a general pardon to all persons who had been engaged in the so-

called house-tax insurrection in Pennsylvania in 1798. Again, in February, 1815, President Madison proclaimed a general pardon to certain persons known as the "Barataria pirates." It is the clear opinion of those legal authors who have discussed the question that the constitutional grant was intended to convey the largest power implied in the word pardon, and that it justified such proclamations as have been referred to, and which were issued in virtue of its assumed authority.—Since the civil war the conditions of the question have been in some respects materially changed. When President Lincoln issued his first proclamation, an act of congress existed, that of July 17, 1862, by which congress had authorized the president at any time thereafter, by proclamation, to extend pardon and amnesty to persons who might have participated in the rebellion in any state or part thereof, with such exceptions and at such times and on such conditions as he might deem expedient for the public welfare. But it appears from the tone of the proclamation itself that the president did not conceive that he derived his capacity from this act, either wholly or even in part. For the preamble runs: "Whereas in and by the constitution of the United States it is provided that the president shall have power to grant reprieves and pardons," &c., and "whereas the congressional declaration for limited and conditional pardon accords with the well established judicial exposition of the pardoning power, I do proclaim," &c. In speaking of the act of 1862 as a "declaration for limited and conditional pardon," the president, it may be assumed, was not giving to the act all the dignity and virtue which congress would have claimed for it. It was in fact a direct intimation that the act was of no effect whatever. At all events, in his next message President Lincoln asserted his exclusive authority under the constitution, and his independence of congress in respect to the pardoning power, even more emphatically than in these proclamations. This provision of the act of July 17, 1862, was repealed on Jan. 21, 1867, the bill for its repeal having become a law by the omission of President Johnson to return it within the prescribed time; so that thenceforth, and until the constitution was amended, the power stood solely on the original provision of the second article. The case of *ex parte* Garland, which is the only recent case that touches the subject, was before the supreme court in 1866. Garland, the petitioner, had received in July, 1865, and of course while the section of the act of 1862 was in operation, "a full pardon and amnesty" for all offences. No particular reference was made on the argument to the effect of that act, but the petitioner's counsel quoted the language of the constitution, and relied on the broad construction given to it by Marshall and others. The court in rendering its decision held that the power conferred on the president by the constitution was unlimited, with the single exception stated

in it, and that it extended to every offence known to the law, and might be exercised at any time after its commission, either before legal proceedings were taken, or during their pendency, or after conviction and judgment; and it said further that the power was not subject to legislative control, and that congress could neither limit the effect of his pardon nor exclude from its exercise any class of offenders. Though this case is not decisive in respect to the power of granting general amnesty, as the proclamations which have been issued assume to do, the case being one of a special pardon, yet it is at least significant upon the point of the exclusive function of the president in respect to pardons in virtue of the constitutional provision, and against the claim that it is to be shared in any respect with congress.—In 1868 the constitution was changed by the adoption of the fourteenth amendment. This amendment introduced provisions which were thenceforth of a force and validity as high and controlling as the original provision itself, and the two articles are therefore now to be construed together. From the considerations which have been already adduced, it should seem that it was believed that the claim of congress to participate in the pardoning power could be well disposed of only in this way. This provision, it will be seen, expressly brings within the reach and control of congress the cases of the most important offenders in the late war; but it does not, it is conceived, annul the power of the president to grant pardons and amnesties to others than those who are especially described, nor does anything in the amendment throw any light on the right construction of the power under the provisions of article second. As to all else relating to that power and its scope beyond that part of it which is reserved to congress by this amendment, we are remitted to the same general considerations and arguments which have been here suggested. The amendment (July 28, 1868) is in these words: "No person shall be a senator or representative in congress, or elector of president or vice president, or hold any office, civil or military, under the United States, or under any state, who, having previously taken an oath as member of congress, or as an officer of the United States, or as a member of any state legislature, or as an executive or judicial officer of any state, to support the constitution of the United States, shall have engaged in insurrection or rebellion against the same, or given aid or comfort to the enemies thereof. But congress may by a vote of two thirds of each house remove such disability."—In January, 1872, in the case of Klein against the United States, the supreme court held doctrines which sustain the positions here taken in respect to the president's power to grant general amnesty under the original provision of the constitution. This case arose before the fourteenth amendment was adopted, and it involves the effect and validity of an act of July 12, 1870 (16 U. S.

Statutes, 235), by which congress had attempted to annul the benefits of pardon or amnesty granted by the president, especially with reference to suits by pardoned rebels in the court of claims. The claimant in Klein's case had done certain acts in aid of the rebellion, but he had accepted a pardon under one of the proclamations of amnesty, and had taken and not violated the oath of future fidelity which was prescribed by it. The act of July 12, 1870, provided that the acceptance of any such pardon should be conclusive evidence of the disloyal acts pardoned, and that on proof of such pardon and acceptance, and on account of the very disloyal acts so proved, the court of claims and the supreme court on appeal should decline jurisdiction of any suit on the part of such pardoned rebel. But the court held that congress had no power to make any such law, and refused to enforce its provisions. With reference to the repeal in 1867 of the act of 1862 already referred to, Chief Justice Chase says that the repeal was made after, and he fairly implies in consequence of, the decision in the Garland case, where it had been held that the president's power of pardon was not subject to legislation, and that congress could neither limit the effect of his pardon nor exclude from its exercise any class of offenders. The court also sustained the position assumed by President Lincoln in regard to his exclusive authority under the constitution. The court further held that "it is the intention of the constitution that each of the great coördinate departments of the government, the legislative, the executive, and the judicial, shall be in its sphere independent of the others. To the executive alone is intrusted the power of pardon, and it is granted without limit. Pardon includes amnesty. It blots out the offence pardoned, and removes all its final consequences. It may be granted on condition. In these particular pardons" (that is to say, under proclamations of amnesty, for the case before the court was one of that sort), "that no doubt might exist as to their character, restoration of property was expressly pledged, and the pardon was granted on the condition that the person who availed himself of it should take and keep a prescribed oath. It is clear that the legislature cannot change the effect of such a pardon, any more than the executive can change a law. The court is required to disregard pardons granted by proclamations on condition, though the condition has been fulfilled, and to deny them their legal effect." This the court declined to do, and affirmed the judgment of the court of claims, which had awarded restitution to the claimant.

AMEBA. See ANIMALCULES.

AMONTONS, Guillaume, a French physicist, born in Paris, Aug. 31, 1663, died Oct. 11, 1705. He was deprived of hearing in early life by disease. It is said that he refused to make any effort to relieve his malady, and devoted himself diligently to the study of geometry and

mechanics. He wrote several important treatises upon scientific subjects, and constructed some new instruments in physical science. He conceived the idea of communicating between distant points by signals to be observed through magnifying glasses, and made successful experiments before the royal family, though the use of the signal telegraph was not introduced till nearly a century afterward.

AMOOR, Amur, or Saghalien, a river in N. E. Asia, formed by the confluence of the river Shilka, flowing N. E. from the Trans-Baikal region in central Siberia, and the river Argoon, coming from Mongolia nearly in the same direction. The two rivers unite at the spot called *Strutchynaya Stanitza* (Shooter's Post), in about lat. $53^{\circ} 20' N.$, and lon. $121^{\circ} 30' E.$ The Amoor runs between the Russian Amoor Country and northern Manchuria, making an arc, and penetrating S. as far as lat. $47^{\circ} 30'$; then flowing N. E. it empties in nearly the same latitude with its rise, in lon. $141^{\circ} E.$, into the gulf of Amoor, W. of the island of Saghalien, a gulf connected by straits N. and S. with both the sea of Okhotsk and the sea of Japan. The whole length of the river is about 2,400 m. Its principal northern affluents are the Oldo, Jenkiri, Bureya, and Amgoon; its southern, the Songari and Usuri. The Amoor is navigable for its whole length; its estuary, however, is filled with sand and soft mud, rendering the passage difficult for 30 to 40 m. from the mouth. It freezes throughout its course at the beginning of November, and remains frozen till March, forming a highway for sledges. During winter the shores are visited by heavy snow storms, called in Siberia *purga*. Both shores are covered with thick forests of pine, oak, lime, maple, and cork trees. The river abounds with fish, and contains some previously unknown species of sturgeon. A steamer called the America, built in New York for the navigation of this river, first ascended it in 1857.

AMOOR COUNTRY, that part of Manchuria recently annexed to Russia. It embraces all the territory on the left bank of the Amoor, together with the coast districts east of it and of its affluent the Usuri, as far south as the river Tumen on the frontier of Corea. In its widest sense, it is situated between lat. 42° and $57^{\circ} N.$, and lon. 120° and $145^{\circ} E.$ By a ukase of Dec. 20, 1858, the country was divided into the "province of the Amoor," and the "sea district of the Amoor Country." The latter forms a part of the "littoral province of East Siberia." The province of the Amoor embraces the country on the left bank of the Amoor; capital, *Blagovieshtchensk*; area estimated at 109,053 sq. m.; pop. in 1867, 22,297. The principal towns in the sea district of the Amoor Country are *Nikolayevsk* and *Sofyevsk*. The island of Saghalien is generally included in the territory of the Amoor Country, the whole of which has an area of about 276,300 sq. m. The principal mountains are the *Stanovoi* along the northern frontier, and off-

shoots of the Chingan mountains in the west. The winters are very severe, and navigation is generally closed from the end of October to the beginning of May. The soil is fertile. Many plants of southern Asia are met with; the rivers swarm with fish; and extensive gold fields have recently been discovered. Although the Russian government has endeavored to develop the resources of the country, its commerce made no progress during the period from 1860 to 1870. The native population consists of about 10,000 Tungusians, divided into eight tribes. In September, 1860, the Russian government organized a force of Cossacks of the Amoor to defend the southern frontier and to settle the territory.—The first knowledge of the country of the Amoor was obtained by the Russian authorities in East Siberia, in 1639. Several expeditions, undertaken by Russian adventurers, led to protracted hostilities with the Chinese, until in 1689 the peace of *Nertchinsk* secured the whole territory to the Chinese. In 1849 the Russian plans of conquest were resumed. After exploring the coast for several years and establishing the forts of *Nikolayevsk* and *Mariinsk*, a large military force was sent in 1854 into the country of the Amoor, and established the Russian rule upon a lasting basis. A ukase of Oct. 31, 1856, proclaimed the union of the lower part of the Amoor Country with *Kamchatka*, and made *Nikolayevsk* the seat of government. By the treaty of *Aigoon*, May 28, 1858, ratified by the commercial treaty of *Tientsin*, June 13, the whole country of the Amoor was ceded by China to Russia. The eastern and western line between Russia and China was regulated by a treaty concluded at *Peking* on Nov. 14, 1860.—For an account of the attempt to construct a telegraph from *Nikolayevsk* to *San Francisco* in 1863-'7, see TELEGRAPH. Concerning the country and river, see *Collins*, "Exploration of the Amoor River" (Washington, 1858), and "A Voyage down the Amoor, with a Land Journey through Siberia," &c. (New York, 1860).

AMOR. See *Eros*.

AMORETTI. I. Carlo, an Italian scholar, born at *Oneglia*, March 13, 1741, died in *Milan*, March 24, 1816. In 1757 he joined the order of *St. Augustine*, and some years later became professor of canon law in the university of *Parma*; but in 1772 he obtained a dispensation from his monastic vows, and entered the ranks of the secular clergy. He was appointed curator of the *Ambrosian library* at *Milan* in 1797, and was the first to make known its treasures to the world. He published from the manuscripts in this collection *voyages of Pigafetta* and *Ferrer Maldonado*; wrote an excellent life of *Leonardo da Vinci*, from original materials; and prepared several treatises on natural science. His *Nuova scelta d'opuscoli interessanti sulle scienze e sulle arti* (27 vols. 4to, 1775-'88) familiarized the Italians with the scientific progress of other nations. **II. Maria Pellegrina**, niece of the preceding, who bestowed great

pains upon her education, born at Oneglia in 1756, died in 1787. At the age of 16 she sustained, in public, arguments on various topics in philosophy. She studied law, and at the age of 21 graduated at Pavia, and received from the university her doctor's diploma. She wrote a treatise on Roman law, which was published after her death.

AMORITES (according to Simonis and Ewald, highlanders), the most powerful tribe of the Canaanites, to all of whom the name is occasionally applied in the Hebrew Scriptures. They dwelt W. of the Jordan, in the territory subsequently allotted to Judah, chiefly in its mountainous portion; and E. of that river they held the two kingdoms of Heshbon and Bashan, of the latter of which the gigantic Og was king when Moses invaded their country. They were a people of large stature and great prowess, and the Israelites had long and severe contests with them, under Moses, Joshua, and other leaders.

AMORTIZATION, or **Amortizement** (law Lat. *amortizare*), in old English law, the alienation or conveyance of real estate to corporations. It was prohibited by a series of statutes, the earliest of which, the Magna Charta of Henry III., applied only to ecclesiastical, but which were subsequently extended to all corporations. Their influence is not yet extinct, either in England or America, though the powers of corporations have been much enlarged in both countries, and in some states put upon the same footing in this regard with those of private parties. These statutes were called the statutes of *mortmain*, as forbidding conveyances into dead hands; hence amortization.

AMORY, Thomas, an English author, born about 1691, died Nov. 25, 1788. He was educated as a physician, but lived chiefly in retirement on a small income. In 1755 he published "Memoirs of several Ladies of Great Britain," all of whom were, like himself, zealous Unitarians; and in 1756 appeared the first volume of his better known and very curious "Life of John Bunce, Esq.," in which he is supposed to have sketched his own picture. The second volume was published in 1766. He was a man of learning, ability, and deep religious convictions, but very eccentric.

AMOS, one of the minor prophets, who prophesied in the days of Uzziah, king of Judah, and Jeroboam II. of Israel, toward the close of the 9th century B. C. He was a native of Tekoah in Judah. He does not appear to have been educated as a prophet, but according to his own account was taken from his flocks to prophesy. His prophecies were especially addressed to the kingdom of the ten tribes, and were delivered in the time of their greatest prosperity as a separate people. They denounce the idolatry practised at Bethel, Gilgal, Dan, and at Beersheba in Judah, and also the sins of the nations bordering on both Hebrew kingdoms, and predict punishment, as well as a brighter future for the Israelitish people.

AMOSKEAG. See MANCHESTER, N. H.

AMOY (Chin. *Hia-men* or *Sya-min*; Fr. *Emouy*), a seaport town of the province of Fokien, China, situated at the S. end of an island of the same name, in lat. 24° 40' N., lon. 118° 13' E., opposite the centre of the island of Formosa; pop. about 250,000. It is built upon rising ground, facing a very spacious and excellent harbor, contains many large buildings, had at the time of the British invasion several considerable forts, one of them 1,100 yards long, and is reckoned to be nearly 9 m. in circumference. It is the port of the large inland city of Chang-choo-foo, with which it has river communication. Its inhabitants are chiefly employed in trade, and its merchants are reckoned among the most enterprising in China. The port was open to the world till 1734, when it was closed. It was captured by the British in 1841, and by the treaty of Nanking was thrown open, first to Britain, then to all nations alike. The native merchants carry on an extensive trade coastwise, and with Formosa, Manila, Siam, and the Malay islands. The foreign imports in 1870 were valued at \$4,500,000, and the exports at \$2,300,000. Amoy is a principal seat of Protestant missionary activity, and the missions of the Reformed church of America and other denominations in 1869 numbered 1,271 communicants.

AMPÈRE. I. **André Marie**, a French physicist and mathematician, born in Lyons, Jan. 20, 1775, died in Marseilles, June 10, 1836. As a boy he showed a singular passion for mathematics, in which at 10 years of age he had made remarkable progress, but could not be persuaded to apply himself with zeal to other studies. He finally consented to study Virgil, that he might be able to master the works of Euler and Bernoulli, which were then accessible only in Latin. At the age of 18 he had gone through the whole range of scientific studies, and had read the great encyclopædia of Diderot and D'Alembert so thoroughly, that 40 years afterward he could still repeat whole pages of it. The death of his father by the guillotine during the revolution affected him so that for upward of a year his friends feared that his intellect had been permanently impaired. In 1802 he was appointed professor of mathematics at Lyons, a post which he owed to his first publication, "Considerations upon the Mathematical Theory of Games of Chance." In 1805 he became a teacher in the polytechnic school at Paris, in 1808 inspector general of the university, in 1809 professor of mathematical analysis in the polytechnic school, and in 1814 a member of the institute. In 1820 he began to devote much attention to the phenomena of electro-magnetism, and in 1824-'6 published *Recueil des observations électro-dynamiques* (2 vols.), a work characterized by profound thought and extraordinary philosophical sagacity. His publications are numerous, many of them being contributions to the *Journal de l'école polytechnique* and the

Mémoires de l'institut. Ampère was a man of genial humor and great simplicity of character, and singularly ignorant of the world, from which he lived retired. He was engaged on his last great work, "The Classification of the Sciences," at the time of his death. **II. Jean Jacques Antoine**, son of the preceding, born in Lyons, Aug. 12, 1800, died March 27, 1864. His education was completed under the supervision of his father at Paris, where he enjoyed the friendship of Mme. Récamier and Chateaubriand. He pursued a course of philosophy with Cousin, and early conceived a passion for English and German literature, romance, and belles-lettres. After some years devoted to travel and literary pursuits, he was in 1833 appointed professor of the history of French literature in the college of France. His work on the early and mediæval literature of France (4 vols.) was a résumé of his lessons. In 1842 he was elected a member of the academy of inscriptions and belles-lettres, and five years afterward of the French academy. He visited many parts of Europe and the East, studied successfully the hieroglyphics of Egypt, and contributed to the *Revue des Deux-Mondes* a well written series of articles on a journey in Egypt and Nubia in 1844. He also made an extended tour in the United States, paying much attention to aboriginal remains and antiquities, and observing carefully the habits of the people. The result of his travels was published in the *Revue des Deux-Mondes*. His works entitled *De la Chine et des travaux de Rémusat*, and *La Grèce, Rome et Dante*, evince his knowledge of languages and general literature; and he published in 1841 a valuable essay on the formation of the French language. Among his other works is *L'Histoire romaine à Rome* (4 vols. 8vo, 1856-'64), a novel application of archæology to literature and politics. His *Correspondance*, constituting an autobiography, was published in Paris in 1872.

AMPFING, a village of southern Bavaria, on the Isen, 5 m. W. of Mühldorf, noted as the scene of a terrible conflict in 1322 between the emperor Louis the Bavarian and Frederick of Austria, generally known as the battle of Mühldorf, in which Frederick was entirely defeated and captured. In 1800 the famous retreat of Moreau was begun here.

AMPHIARÆUS, a mythical hero and seer of Greece, the son of Oicles and Hypermnestra. He was married to Eriphyle, sister of Adrastus, king of Argos, by whom he had numerous sons. Having sworn that he would abide by the decision of his wife on any difference which might arise between himself and Adrastus, Eriphyle took advantage of this oath to force Amphiaræus to join in the enterprise of the seven against Thebes. Before setting out he made his sons promise to punish her treachery. (See ALCEON.) At the siege of Thebes he greatly distinguished himself, but being pursued by Polydorus, he fled toward the river Ismenius, where the earth opened and swal-

lowed him. Jupiter made him immortal. An oracle of Amphiaraus, near Thebes, enjoyed great reputation among all the Greeks.

AMPHIBIA, animals which frequent both land and water. There is probably no truly amphibious animal, as that would imply the possibility of living and breathing equally well in air and in water. The old naturalists gave the name to beavers, otters, frogs, and other animals from all the orders of vertebrata; Linneus restricted the term to reptiles with cold blood and simple circulation; Cuvier called amphibia such mammals as can dwell on land or in the water, like the seal, the walrus, and the dugong, occupying a position intermediate between the feline and the marsupial animals. There are animals which have both gills and rudimentary lungs, as the proteus, the siren, and the menobranchus, but they are decidedly aquatic, and perish sooner or later in the air. The *amphibia* constitute an order of reptiles (the *batrachia* of later herpetologists), and may be characterized as vertebrated animals, with cold blood and naked skin, reproducing by means of eggs, and most of them undergoing a metamorphosis or change of condition, having relation to a transition from an aquatic respiration by gills to an atmospheric respiration by lungs, and a consequent alteration in general structure and mode of life. These characters have led some writers to consider the amphibia as a distinct class, instead of a mere order of reptilia. No arrangement proposed by naturalists presents a perfect division of the different forms: the following by Mr. Thomas Bell of London, founded on the absence or presence and duration of the gills, seems the most natural: Class AMPHIBIA, Order 1. ΑΜΦΙΠΝΕΥΡΑ. Body elongated, formed for swimming; feet either four, or two anterior only; tail compressed, persistent; respiration aquatic throughout life, by external persistent gills, coexisting with rudimentary lungs; the eyes with lids. Genera, *proteus*, *siren*, *siredon*, *menobranchus*, *pseudobranchus*.—Order 2. ΑΝΟΥΡΑ. Body short and broad; feet during the tadpole state wanting, afterward four, the hinder ones long and formed for leaping; tail before the metamorphosis long and compressed, afterward wanting; ribs wanting; vertebrae few and ankylosed together; respiration at first aquatic by gills, afterward atmospheric by lungs; gills at first external, but withdrawn into the chest before the metamorphosis; impregnation effected externally during the passage of the eggs. Genera, *rana*, *hyla*, *ceratophrys*, *bufo*, *rhinella*, *otilopha*, *dactylethra*, *bombinator*, *breviceps*.—Order 3. ΥΡΟΔΕΛΑ. Body long and slender; feet always four; tail long and persistent; ribs very short; respiration at first aquatic by external gills, afterward atmospheric by cellular lungs; vertebrae numerous and movable; impregnation internal. Genera, *salamandrina*, *salamandra*, *meloe*.—Order 4. ΑΒΡΑΝΧΙΑ. Body long and formed

for swimming; feet four; cranium solid; tail compressed; respiration by lungs only; gills absent; no metamorphosis known. Genera, *menopoma*, *amphiuma*.—Order 5. APODA. Body elongated, slender, and snake-like; feet none; tail very short, almost wanting; lungs, one larger than the other; ribs very short; breast bone wanting; impregnation unknown, probably internal. The existence of gills at any period of life is unknown. Genus, *cæcilia*.—In the adult amphibia the skeleton varies considerably. In the frog, which moves extensively on land, we find the hind legs greatly developed to enable it to take the enormous leaps by which it pursues its prey and escapes from danger; hence it has no useless tail, the body is contracted longitudinally into a short space, and the vertebræ are few, united into a single immovable piece unprovided with ribs. On the contrary, the water salamanders or newts have a long tail, a slender flexible body, and all their organs fitted for aquatic life. The structure of the bones is more compact and calcareous, and less transparent and flexible, than in fishes. The bones of the skull do not overlap each other, but have their margins in contact and occasionally united; the bones of the face are more closely united to those of the skull than in the fishes; the intermaxillary and jaw bones are much developed transversely, expanding the general form of the skull without involving any enlargement of the brain cavity, which is very small. The hyoid bone experiences most remarkable changes in those genera which undergo metamorphosis. In the highest amphibia, the bones of the spine are very few; in the frog there are 9, in the pipa only 8, unprovided with ribs, but having long transverse processes; the anterior articular surfaces of the bodies are concave, and the posterior convex. In the tadpole, and in the genera which retain their gills through life (*siren*, *menobranchus*, &c., hence called perennibranchiate), the substance between the vertebræ is soft, and contained in cup-like hollows formed by the concave articular surfaces of contiguous bones, precisely as in fishes; another proof of the intermediate condition of these lower forms of the class. In the salamanders the vertebræ are more numerous, especially those of the tail; in the siren the trunk has 43, and the tail as many more. The limbs are arranged on very different plans in the different groups; in the frogs and toads they are well developed, and suited for active leaping and swimming; in the elongated aquatic species the limbs are small and feeble; in *cæcilia*, there are not even the rudiments of limbs; in these the imperfect development of the extremities is compensated by the extent of the spine of the body and tail, by the curves and flexures of which they swim with considerable rapidity. In the fish-like tadpole, the limbs are at first scarcely perceptible, and in their gradual development acquire a considerable size and well-defined form while yet im-

prisoned beneath the skin; the hind legs are first seen; the tail is much developed, gradually disappearing by absorption as the limbs acquire their full size. All the amphibia have teeth on the palate; the salamanders have them also in both the upper and lower jaws, the frogs in the upper only, and the toads in neither; the jaw teeth are always slender, sharp-pointed, and closely set; the frog has about 40 on each side of the upper jaw; the salamander has about 60 above and below; the palatine teeth are generally arranged transversely, parallel to the jaw teeth. In the adult amphibia the gullet is wide and short; the stomach is a simple sac, elongated in the aquatic species; the intestine is but slightly convoluted, and terminates in a cloaca, or pouch, which also receives the openings of the genital and urinary organs. The vent in the frogs and toads opens on the hinder part of the back; in the other forms it is beneath the commencement of the tail, as in ordinary reptiles. The liver, pancreas, and spleen are found in all the class. The lymphatic and laeteal systems are extremely developed; in the course of the lymphatics are found pulsating cavities or ventricles which propel their contents toward the veins, but their pulsations do not coincide with those of the heart, nor those of one side with those of the other. In the circulating system we find the most convincing proof of the intermediate position of the amphibia; they begin life with the single heart and gills of fishes, but as their metamorphosis goes on, the heart assumes the compound character necessary for the pulmonary respiration of the reptiles. The heart in the early stage of these animals consists of a single auricle which receives all the blood after its circulation, and a single ventricle which sends it through a third cavity, the *bulbus arteriosus*, to the gills or branchiæ; in the gills the blood is purified by the oxygen of the water, and returned by their veins to the aorta; from the last branchial artery a branch is given off on each side, which goes to the rudimentary lungs and afterward becomes the pulmonary artery; between the branchial arteries and veins are small communicating branches, which, as the gills are absorbed, gradually enlarge until they form continuous trunks, and the original branchial artery becomes the root of the two descending aortæ, at the base giving off the pulmonary artery; the two veins which return the blood from the rudimentary lungs enlarge as these organs are developed, and become the pulmonary veins, which last, being distended at their point of union with the heart, ultimately form the second auricle. The circulation, then, of the adult amphibia assumes the character which we find in the reptiles generally, being performed by a single ventricle and two auricles; the pure blood in the pulmonic auricle and the impure blood in the systemic auricle are sent together and mixed in the single ventricle, so that a half-purified blood is distributed to the

organs. The gills, whether external or internal, are expanded in a leaf-like form, considerably divided, though much less so than in fishes; in the earliest stages they are always external, and remain so permanently in the order *amphipneura*, but in the higher orders they become very soon internal; they are supported by cartilaginous or bony arches connected with the hyoid bone, which changes its form in accordance with the development of the respiratory organ. On the leaflets of the gills the minute blood vessels run, bringing the venous blood into contact with oxygen, and sending it back purified to the heart. While some amphibia retain their gills through life, with coexistent rudimentary lungs, others lose them entirely as the lungs are developed, so that there probably is a brief period in the life of some of these animals in which they may truly be called amphibious. In the caducei-branchiate genera (or those which lose their gills), the early condition of the lungs is that of a mere sac without any appearance of the cells or pulmonary structure afterward developed; it becomes, therefore, an interesting question whether the similar rudimentary lungs of the perennibranchiate genera can serve any of the purposes of respiration. From the mechanism of respiration in the higher genera, and the anatomical deficiencies in the accompanying apparatus in the lower, it would be at once seen that these simple sacs could hardly aid the gills, and much less could perform their office in aerating the blood. Rusconi concludes that in the proteus, at least, these sacs do not assist in respiration; and experiments alluded to in the "Proceedings of the Boston Society of Natural History," vol. vi., p. 153, show that the menobranchus perishes in about four hours when removed from the water. In the higher orders, the reception of air into the lungs is effected by a simple act of swallowing; the air enters the mouth through the nostrils, and, the gullet being closed, is forced into the lungs by the action of the muscles of the hyoid bone. The fish-like structure of the nostrils in the lower genera, and the imperfect condition of their glottis and windpipe, with the perfect development of the gills, show that, like the air bag of fishes, these simple sacs, though they represent rudimentary lungs, are not for the purposes of respiration proper. The brain offers the same gradations, from the fish-like simplicity of that of the tadpole and lower genera to that of the reptile, in which the hemispheres become enlarged laterally, and the spinal cord shorter and thicker at the origins of the nerves of the limbs. In the frogs the eyes are large and prominent, in the salamanders comparatively small, and in the cæcilia scarcely visible; in all they resemble those of fishes in the flattened anterior surface, the small quantity of the aqueous humor, and the depth of the crystalline lens; the eyes of the frog are fully developed, and provided with lids. In the lower genera and in the tad-

pole state, the organ of hearing is very imperfect, consisting of a hollow in the temporal bone, at the bottom of which is the sac containing the cretaceous body on which the nerve is spread; there is no drum nor tympanic cavity; the organ is covered by the skin, without any external communication. In the frog the ear is more complicated, having the drum with its cavity and bones, and communicating with the mouth by a Eustachian tube. The sense of smell must be imperfect in the amphibia; in the lower forms the nostrils are mere cavities in the front of the head, with no communication with the mouth, as in fishes; in the higher orders the nose communicates with the mouth, but in them the apparatus for smelling is probably less sensitive than in the lower forms, the nose being more connected with the act of breathing. The sense of taste is probably also very obtuse; in the frogs and toads the tongue is developed to an extraordinary degree, being long, with the anterior half free, doubled back on itself, and capable of being thrown forward and retracted with great quickness, serving for the seizure of the insects on which they feed, and for conveying them instantly to the back part of the mouth. The amphibia are distinguished from reptiles by the absence of all scaly covering; a naked skin characterizes all, from the snake-like cæcilia to the fish-like axolotl. The skin of the aquatic genera is soft, smooth, and kept constantly moist by the cutaneous secretions; in the land genera, as frogs and toads, the glands of the skin secrete a thick whitish fluid, which may become acrid and irritating, giving rise to the opinion that these secretions are poisonous; in the salamander the fluid thus poured out is so abundant, and so suddenly secreted when the animal is irritated, that it is quite probable that even the effects of fire may be for a short time arrested by it—doubtless the origin of the well known fable in regard to this animal. The cuticle is frequently shed; that of the aquatic genera being washed away in shreds, while that of the toads is divided along the median line, removed by the contortions of the animal, and finally swallowed at a single gulp. The amphibia breathe by the skin as well as by the lungs and gills; a frog will live from five to six weeks in a state of complete strangulation, and even after total excision of the lungs; indeed, the pulmonary respiration is insufficient to support life in these animals without the assistance of the skin. The medium through which the blood is oxygenated, whether lungs, gills, or skin, whether in air or in water, is always a modification of the cutaneous surface; and, as in frogs the same surface is capable of performing both aquatic and atmospheric respiration, it is natural to infer that lungs and gills are identical in structure. The amphibia, like many of the invertebrate animals, have the power of reproducing parts lost by accident or design; the common water salamander will invariably restore the limbs which have been cut off for experiment, and even re-

peatedly; the common land salamander also reproduces its tail, which it so easily separates in case of need. Impregnation is effected without sexual congress, except in the land salamander; in the order *anoua*, the male embraces the female with great tenacity, and impregnates the eggs, several hundred in number, as they are ejected under his pressure; in the tailed aquatic species, impregnation takes place during the instantaneous apposition of the cloacal openings of the two sexes. The testes and ovaries are double, and symmetrically arranged; they are much enlarged at the breeding season. When the young are ready for aquatic life, they burst the thin membrane of the egg, and come out in the fish-like form. In the terrestrial salamander, whose habits do not permit this mode of development, the young undergo their metamorphosis in the oviduct, in which they pass their tadpole state, and appear without gills when they are ready for terrestrial existence. Like the viper, the salamander is ovoviviparous. In the pipa, or Surinam toad, the eggs, instead of being dropped into the water, are placed by the male on the back of the female; here they are attached by a thick mucus, and the skin gradually thickens in the intervals so as to form a cell around each egg; in these cells the young undergo their metamorphosis, and come from them perfect animals. After the young are hatched out, the cells of the female disappear. Like many of the saurian and chelonian reptiles, some of the amphibia are used as food. The delicacy of the frog's thigh is well known to the epicure. The Mexicans consider the sireon or axolotl very good eating; and it is quite probable that, like the reptile iguana, many of the hideous amphibia are wholesome articles of food.

AMPHICTYONS, members of an amphictyony, a term used by the ancient Greeks to designate an association of neighboring tribes or cities for the observance of the law of nations toward each other, and the protection and worship of some deity, whose temple was supposed to be the common property of all. The word is sometimes derived from the mythical hero Amphictyon, son of Deucalion and Pyrrha, but is properly a compound from *ἀμφί* and *κίλιω* or *κίλιω*, signifying "dwellers around" or "neighbors." The origin of these associations is enveloped in much obscurity, and beyond the fact that several of them existed in Greece at a very remote period, forming as it were the germ of one of the strongest bonds of union by which the Greek tribes were held together, we know nothing of the circumstances of their formation. The most celebrated of these confederations was that known as the amphictyonic council, which from small beginnings rose to great importance, on account of the wealth and magnificence of the temple of Apollo at Delphi, of which it was the special guardian. It was composed of 12 tribes, variously described by the authorities, but generally supposed to comprise the Ionians, Dolopians, Thes-

salian, Etæans, Magnetes, Malians, Phtlian Achæans, Dorians, Phocians (including the Delphians), Locrians, Bœotians, and Perrhæbians, all of whom originally dwelt in and around Thessaly and were of equal importance, although subsequently we find them distributed over all parts of Greece. Some became utterly insignificant or extinct, and the fact of the Dorians standing on an equality with the Dolopians or Malians shows that the council must have existed before the Dorian conquest of the Peloponnesus. The council met twice a year, in the spring at the temple of Apollo at Delphi, and in the autumn at that of Ceres at Anthela, near Thermopylæ, and was represented by two classes of deputies from each tribe, the hieronmemons and the pylagoræ, whence it has been supposed that two amphictyonies, organized for the worship of two distinct deities, were subsequently merged in one. The 12 tribes had equal rights at the meetings of the council, and each was entitled to two votes, to be given by its deputies. The objects of the confederation are best described in the following oath which each of its members was obliged to take: "We will not destroy any amphictyonic town, nor cut it off from running water in war or peace; if any shall do so, we will march against him and destroy his city. If any one shall plunder the property of the god, or shall be cognizant thereof, or shall take treacherous counsel against the things in his temple at Delphi, we will punish him with foot and hand and voice, and by every means in our power." Notwithstanding the humane and wise objects of the council, it engaged in two sanguinary wars against some of its own members, called the first and second sacred wars, and finally lent itself to the ambitious purposes of Philip of Macedon, who in the name of the league excited a third war in 338 B. C., in which the liberties of Greece were extinguished at the battle of Chæronea. The first of these wars, which began in 595 B. C. and lasted till 585, was declared against the Phocian city of Crissa, on account of injuries inflicted upon persons visiting the oracle of Apollo at Delphi, and resulted in the total destruction of the city. The second sacred war, from 355 to 346 B. C., originating in a charge against the Phocians of taking into cultivation a tract of land belonging to the Delphic temple, was carried on with such vindictiveness that nearly every Phocian town was destroyed. Philip of Macedon, having entered the struggle at the solicitations of the Thessalians, decided the war in their favor, and thus gained his fatal ascendancy in the affairs of Greece. The Phocians were ejected from the league at the close of the war, but were subsequently readmitted. The duration of the amphictyonic council is not precisely known, but it survived the independence of Greece.

AMPHILOCHUS, a legendary hero of Greece, the son of Amphiaras and Eriphyle, and brother of Alcmaeon. He took part in the war of the epigoni against Thebes, aided his

brother in the murder of their mother (see ALCEON), and subsequently joined the expedition against Troy. He was celebrated for his prophetic gifts, and had an oracle at Mallus in Cilicia (a city said to have been founded by Amphiloehus and Mopsus), which was esteemed the most truthful of all oracles; and at Athens, Oropus, and Sparta he shared in the divine honors paid to Amphiaræus.

AMPHION, in Greek mythology, a son of Zeus and Antiope, the wife of Lycus, king of Thebes. He and his brother Zethus were exposed on Mount Cithæron, but were found and brought up by shepherds. Mercury, or according to others Apollo or the muses, gave a lyre to Amphion, who from that moment devoted himself altogether to song and music. To avenge the wrongs of their mother, the brothers undertook an expedition against Thebes, which they captured and fortified, slaying both Lycus and his new wife Dirce. They then built a wall around the town, Amphion playing on his lyre, and the stones moving in obedience to its notes whither they were wanted till it was finished. Amphion married Niobe, by whom he had many sons and daughters, all of whom were killed by Apollo.

AMPHIPOLIS (now *Jenikeui*), a city of ancient Macedonia, on the Strymon (now Struma, or Kara Su), near its mouth. It was originally called Ennea Hodoi (Nine Ways), and held by the Thracian Edonians, and received its historical name from an Athenian colony which occupied it in 437 B. C. It was besieged by the Lacedæmonians under Brasidas during the Peloponnesian war, and compelled to surrender to them (424). Later it fell into the hands of Philip of Macedon, and under the Romans it was the capital of a Macedonian district. In the middle ages it was called Popolia. There are few remains of the town.

AMPHISBÆNA (Gr. ἀμφίσβαινα, an animal that can move or walk in both directions), the name of a genus of saurians. The head is so small and the tail so thick and short that it is difficult to distinguish one from the other at first sight; and this peculiarity of form, in addition to the animal's habit of proceeding with equal facility either backward or forward, has given rise to the popular belief in Brazil and other parts of South America, where the amphispæna most abounds, that it possesses two heads, one at each extremity. These saurians are distinguished from others by their nearly uniform thickness of body from the head to the extremity of the tail, by their small mouths and extremely diminutive eyes, remarkably short tails, and numerous rings of small square scales, completely surrounding the body and the tail. The jaws are furnished with a single row of small conical teeth, few in number and distant from each other, and the palate is toothless. These reptiles are also destitute of fangs, and are therefore harmless. They live mostly on ants and other small insects, and inhabit ant hills and burrows which they make

for themselves under ground. The genus *amphisbæna* contains only a few species, confined to Brazil, Guiana, and other tropical parts of the American continent. The *A. fuliginosa* is

Amphisbæna fuliginosa (Sooty Amphispæna).

the best known species. It is found in the hotter regions of South America, and does not inhabit Ceylon or any part of the East Indies, as Linnaeus and Lacépède were led to believe, on the authority of Seba. The general color of this animal is a deep brown, varied with shades of white, more or less clear, according to the season of casting the old and acquiring the new external coat or "skin." It grows to the length of 18 inches or 2 feet, the tail measuring only one inch or thereabouts. The body, about as thick as the wrist of a child of 10 years, is surrounded by upward of 200 rings, and the tail by 25 or 30. The eyes, exceedingly diminutive, are covered by a membrane which almost conceals them; and this has given rise to the popular opinion that the amphispæna has no eyes.

AMPHITHEATRE, with the Romans, an open elliptical building, with an elliptical space in the centre called the arena, from the low wall surrounding which rose tiers of seats, supported on arches, receding to near the summit of the outer wall. These buildings were used for public games or combats between men or beasts, and in later times also for exhibitions of mimic sea fights, and of crocodiles and other amphibious animals, by filling the arena with water. The arena was so called because sand (Lat. *arena*) was usually employed to give a firm footing and to dry up the blood. The wall around the arena varied in height from 8 to 18 feet. On a level with its top spread the first platform, where the chairs of the more honored spectators were placed. From the top of the wall that formed the back of this space rose the first tier of seats, reaching to another platform with another wall at its back, and so on to the top. The box (*suggestus* or

cubiculum) of the chief magistrate or emperor was on a conspicuous part of the first platform (*podium*), as was that of the vestal virgins. A raised seat on the same was also assigned to the giver (*editor*) of the games. At each end of the arena was a large door for the entrance and exit of men and beasts. The latter were kept in dens under the platforms and seats, and were sometimes forced upon the arena through small doors in the side of the wall surrounding it. Sometimes also, if not always, there were vast substructions beneath the floor of the arena containing dens from which the animals might be suddenly sent up through trap doors. Excavations in the amphitheatre at Pozzuoli have shown most clearly these arrangements. On the top of the wall of the arena was a railing of bronze or iron to protect those who sat on the first platform from any sudden spring of the wild beasts. As a further

defence, ditches called *euripi* sometimes surrounded the arena. An awning (*velarium*), supported by ropes and pulleys from strong masts set in stone sockets around the top of the building, appears to have been sometimes extended over the spectators. When the weather did not permit the *velarium* to be spread, broad-brimmed hats or a sort of parasols were used. The first amphitheatre in Rome seems to have been that of M. Curio, described by Pliny. It consisted of two wooden theatres made to revolve on pivots, in such a manner that they could by means of windlasses and machinery be turned round face to face, so as to form one building. Gladiatorial shows were first exhibited in the forum, and combats of wild beasts in the circus; and it appears that the ancient custom was still preserved till the dictatorship of Julius Cæsar, who built a wooden theatre in the Campus Martius for the pur-

Amphitheatre at Verona.

pose of exhibiting hunts of wild beasts. Most of the early amphitheatres were merely temporary and made of wood; such as the one built by Nero at Rome, and that erected by Atilius at Fidenæ in the reign of Tiberius, which gave way during the games and killed or injured 50,000 persons. The first stone amphitheatre was built by Statilius Taurus, at the desire of Augustus. This building, which stood in the Campus Martius near the Circus Agonalis, was destroyed by fire in the reign of Nero, and it has therefore been supposed that only the external walls were of stone, and that the seats and other parts of the interior were of timber. A second amphitheatre was commenced by Caligula; but by far the most celebrated of all was the Flavian amphitheatre, usually called the Colosseum, which was begun by Vespasian and finished by his son Titus,

who dedicated it A. D. 80, on which occasion, according to Eutropius, 5,000, and according to Dion, 9,000 beasts were destroyed. The following table has been compiled to show the proportions of some of the chief amphitheatres:

PLACES.	Length, feet.	Breadth, feet.	Length of Arena, feet.	Breadth of Arena, feet.	Height, feet.	No. of Spectators.
Rome (Colosseum).	615	510	281	176	164	80-100,000
Verona.....	513	410	24½	147	100	22,000
Vienne.....	508	436
Pozzuoli.....	480	382	336	138	...	25,000
Arles.....	459	335	316	130	55½	25,000
Limoges.....	450	378
Nîmes.....	437	332	70	17-23,000
Pompeii.....	430	335	195	107	...	10-20,000
Poitiers.....	426	375	264	210
Pola.....	336	292	75	...

During the middle ages, the amphitheatres were used as castles or as quarries, according to the exigencies of the times; but, in spite of all assaults of man or time, their ruins are among the most stupendous monuments of Roman antiquity.

AMPHITRITE, a nereid or oceanid, the wife of Neptune and goddess of the sea, mother of Triton, Rhode or Rhodos, and Benthesisyme. Jealous of Seylla, she threw some magic herbs into the well in which her rival was accustomed to bathe, and thus transformed her into a monster with six heads and twelve feet. In ancient works of art Amphitrite is always distinguished from Aphrodite by a net which keeps her hair in order, and by the claws of a crab on her forehead.

AMPHITRYON, in Greek legends, a son of Alceus and Hipponome. Having accidentally killed his uncle Electryon, he was expelled from Mycenæ, and forced to take refuge in Thebes. To win the hand of Alcmena, he undertook an expedition against Pterelaus and the Taphians, whose lands he seized and divided among his friends. He was subsequently married to Alcmena, and became by her the father of Iphicles. He was killed in a war which he and Hercules were carrying on against Erginus, king of the Minyans. His tomb was standing at Thebes in the time of Pausanias.

AMPHORA (Gr. ἀμφορεύς, from ἀμφί, on both sides, and ἄρχειν, to carry), a large two-handled

Greek and Roman Amphoræ. From Specimens in the British Museum.

vase, commonly made of earthenware, of various forms, but generally tall and narrow, with a contracted neck, and ending nearly in a point. It was used by the ancients to hold wine, oil, the ashes of the dead, &c.; and some have been found in excavating that had been used as coffins by dividing them in half lengthwise, putting in the body, and joining the parts.—The amphora was also a liquid measure among the Greeks and Romans, equivalent to about nine gallons with the former and six with the latter.

AMPULLA, a Roman vessel, like a bottle, used for holding wine, oil, or water. The *ampulla Rhemensis* (*la sainte ampoule*) was a glass flask filled with holy oil, which, according to tradition, was brought down from heaven by a dove at the time of the coronation of Clovis, at Rheims, in 496. From the 9th century, if not before, down to Louis XVI., all the kings of France were anointed with the oil contained in the sacred ampulla. During the revolution the ampulla was broken and its fragments thrown away. A pious person preserved one of the pieces, and after the restoration of the Bourbons it was delivered to the archbishop of Rheims, with a little of the original oil, as was asserted. Charles X. was anointed from it, and the oil then failed.

AMPUTATION (Lat. *amputare*, to cut off), a surgical operation by which a limb or portion of a limb, or a naturally projecting part of the body, is removed. The cutting away of a tumor is spoken of as an extirpation or excision. Amputation is required where the part is injured or diseased to such an extent as to render it useless and inconvenient, or a source of danger to life if it be retained. For many centuries an operation of extreme danger in itself, and performed only in the most urgent cases, surgical advance has rendered it one of little risk, though of late years there has been a tendency to curtail its sphere by improvements in other departments of the science. It was at first performed by a division of all the parts at the same level, and only through a joint. About the 1st century the practice of amputating between the joints was introduced, and also the very important principle of dividing the bone at a higher level than the soft parts, that the cut surfaces of these latter may be joined together over the bone and unite in that position. Formerly the great source of danger was the hæmorrhage which took place during and after the operation; to prevent which the parts were divided with red-hot knives, or the cut surfaces treated with heated irons or boiling liquids, in order to produce a charring of the tissues and plugging of the mouths of the vessels. A band encircling the limb, to restrain the bleeding during the operation, was used as early as the 1st century, but its permanent arrest was for a long time effected only by the means already mentioned. The band, applied ignorantly, failed of its complete purpose, and the inevitable separation of the eschars produced by hot bodies in many cases opened afresh the vessels, and hæmorrhage and death were the result. The use of the ligature in amputation, especially as its proper application was developed, rendered the operation comparatively safe. The honor of its introduction is probably due to Ambroise Paré in the 16th century. If the ligature was employed in these cases by Celsus, it fell into immediate disuse; and even the teachings of Paré and his school were unable for many years to bring it into general favor. The invention

of the tourniquet by Morel and its perfection by Petit, in the 17th and 18th centuries, still further diminished the dangers. When it is done for a disease, it is spoken of as a pathological amputation; when for an injury, it is named "primary" or "secondary," according as it is performed before or after the occurrence of the inflammation which is induced by the violence done to the part. During the inflammatory period the operation is contra-indicated except for some very urgent reason. The deaths following primary amputations are somewhat fewer in number than those after secondary, except in the case of the thigh. Where done for disease, the mortality is very much less. No rule in surgery is better established than that the death rate increases as we approach the trunk. An amputation of the leg is less dangerous than of the thigh, and that through the lower part of the thigh less than through its upper part. Moreover, an amputation through the upper extremity is less grave than one through a corresponding part of the lower extremity.—In performing amputation, the patient is placed under the influence of an anæsthetic, which by its abolition of pain and much of the terror diminishes the shock to his system, and enables the surgeon to operate more carefully and on a part deprived of motion. The circulation through the main artery is arrested by pressure with the finger or the tourniquet. The skin and muscles are then cut by a series of sweeps of the knife round the circumference of the limb, the parts being drawn toward the trunk by an assistant as each one is completed. In this way, as the bone is approached, the parts are divided at a higher and higher level. The bone is then sawed, the sharp edges or corners being rounded off so as not to press upon the part. The chief arteries are treated in such a way as to close their open extremities. This may be done by grasping the end with the forceps and twisting it several times, which is called torsion; or by pressure with a needle passed through the muscles and over or through the vessel, called *acupressure*; or, most usually, by tying it with a ligature, which consists of a well waxed string of silk or other material. The tourniquet is then removed, and the small vessels which bleed are treated in the same way, provided the contact with the air does not cause them to contract. The soft parts are then drawn over the end of the bone and stitched together. The method of cutting the soft parts described above is known as the circular. What is called the flap operation may be performed by transfixion, cutting from within outward, or by cutting from without inward. In either case a single or a double flap may be made. This latter process may be rendered intelligible by taking a circular piece of paper and folding it along one of its diameters. The centre of the circle would represent the situation of the end of the bone, and the circumference the margins of the skin which are stitched together.

If the cut surfaces grow together at once, there is said to be primary union. This result is but seldom attained, at least throughout, and as a rule the union is secondary, in which case suppuration takes place, and granulations spring up which grow together and fill up the wound.—For the accidents which may occur after amputation, see *GANGRENE, HÆMORRHAGE, NECROSIS, OSTEO-MYELITIS, and TETANUS.*

AMRITSIR, or *Umrirtsir*, a town of the Punjab, Hindostan, between the Ravee and the Beas, an affluent of the Sutlej, 36 m. E. of Lahore; pop. about 130,000. There is in the town an extensive tank, built, or rather restored, in 1581, by Ram Das, the 4th Guru or holy man of the Sikhs, the name of which—Amrirtsir, the pool of immortality—was in the course of time transferred to the whole town. In the centre of the pool is a temple sacred to Goyind Singh, the last of the Gurus. Amrirtsir is a place of considerable trade, one of the commercial depots of N. W. India. It is an open town, but Runjeet Singh built a fort there in 1809.

AMRU IBN EL-AAS, one of Mohammed's early proselytes, died in 663. He belonged to the Koreishites, and in early life was furiously opposed to Mohammed, ridiculing him in epigrams and satirical verses, and even attacking those of the new faith who had settled in Abyssinia. At last, however, he was converted, and his zeal in behalf of his new faith was as uncompromising as his opposition had been. The first two successors of the prophet, Abu Bekr and Omar, were chiefly indebted to his valor for the conquest of Syria. He carried his conquering arms into Egypt, and, at the head of only 4,000 men, took Pelusium and founded Old Cairo. He soon laid siege to Alexandria, and distinguished himself as much by his personal bravery as by his skill and conduct as a general. He was present in the assault, and in an attack on the citadel was taken prisoner with a faithful slave. Brought before the commander of the fortress, his slave, striking him in the face, ordered him to be silent in the presence of his betters; and this device saved his life by leading his conquerors to suppose him a person of no rank. He was sent back to the Mohammedan camp, with a proposition for a truce. This was refused, and the city was taken with a loss to the Arabs of 23,000 men. Amru spared the city, but the orders of Omar subsequently caused the conflagration of the library. Amru became emir of Egypt, and his firm government conciliated the inhabitants. He projected a canal for uniting the waters of the Nile with the head of the Red sea. Having been recalled by Caliph Othman, the Alexandrians in his absence revolted, and surrendered the city to the Greeks. Amru returned, and once more reduced the city and spared the inhabitants. The caliph Moawiyah owed his accession to Amru, who declared for him in preference to his rival Ali.

AMRU'L-KAIS, or *Amruleais*, an Arabian poet, author of one of the seven *Moallaahs*, poems

of the pagan pre-Mohammedan era, which were suspended to the Caaba, whence their name (pl. *Moallaacat*, suspended). He was an opponent of Mohammed, and wrote satirical verses against him. Lette published the *Moallaacah* at Leyden in Arabic, and Sir William Jones the English translation (London, 1782). The poem is purely imaginative. It was republished, together with other productions of the poet, by Baron MacGuekin Slane (Paris, 1857), and also by Arnold, in the *Sep-tem Moallaacât* (Leipsic, 1850).

AMSDORF, Nikolaus von, a German reformer, bishop of Naumburg, born near Wurzen, Saxony, Dec. 3, 1483, died at Eisenach, May 14, 1565. He was educated for the church, and early acquired distinction in theology. He seems to have been the confidant of Luther, and attended him in some of his early trials as a reformer. He was a sort of apostle of the reformation, going to Magdeburg (1524), to Goslar (1528 and 1531), and to the principality of Grubenhagen (1534), as the expounder and defender of the principles of the reformation. He was fond of controversy, and this peculiarity more than once involved him in personal difficulties with his friends. He contended that good works were not only not necessary, but prejudicial to salvation. In the attempt to secure concord between the Lutherans and the Zwinglians (1536), Amsdorf violently opposed the movement, probably on account of his personal hostility to Melancthon. In 1542 he was appointed bishop of Naumburg, and was consecrated by Luther, who boasted of the uncanonical manner in which the service had been performed, as he himself says, "without suet, lard, tar, grease, or coals." This involved him in a contest with Von Pilguk, who had been regularly appointed by the chapter to the same office. Amsdorf was a violent opponent of the Augsburg Interim, and was one of the leaders in the adiaphoristic controversy.

AMSLER, Samuel, one of the greatest German engravers, born at Schinznach, Switzerland, Dec. 17, 1791, died in Munich, May 18, 1849. He passed several years in Rome, and in 1829 was appointed professor of engraving in the academy of Munich. He made a great number of fine engravings from Michel Angelo, Raphael, Schwanthaler, Thorwaldsen, Kaulbach, Overbeck, and other artists.

AMSTEL, a small river of the Netherlands, in the province of North Holland, formed by the union of the Drecht and Mydrecht. It passes through the city of Amsterdam, entering it on the S. E., and, after a winding northerly course of 10 miles, uniting with the Y.

AMSTERDAM, the largest city of Holland, capital of the kingdom of the Netherlands and of the province of North Holland, situated on the S. bank of the Y, an inlet or arm of the Zuyder-Zee, where that is joined by the river Amstel, 10 m. E. of Haarlem and 31 m. N. N. E. of the Hague; lat. 52° 22' N., lon. 4° 53' E.;

pop. in 1870, 281,805, mostly of the Dutch Reformed church, and including about 60,000 Catholics, 36,000 Lutherans, 4,000 Anabaptists, 1,000 Remonstrants, 28,000 German and about 3,000 Portuguese Jews. It is one of the most remarkable cities in the world, resembling Venice in the intermixture of land and water, but much larger than Venice, and the canals, being lined with quays, present scenes of animation and enterprise. At the beginning of the 13th century it was but a small fishing village, subject to the lords of Amstel. It was constituted a town in the middle of that century; was taken possession of by William III., count of Holland, in 1296; fortified in 1482; was for a long time strongly Catholic (the Protestant citizens having been driven out by the duke of Alva), and joined the confederation of the United Provinces in 1578. Free toleration was now granted to all sects and religious beliefs, and with additional privileges granted to it in 1581 by the prince of Orange, and the ruin of its rival city Antwerp by the closing of the Scheldt in 1648, it soon reached a highly prosperous state, and has since advanced with but few interruptions, owing chiefly to wars with England, till it is at present one of the wealthiest cities in the world. The form of the city is that of a crescent, the arms projecting into the Y, and thus forming the port. The enormous dams thrown up since 1851 resist the influx of the sea into the canals, and are provided with floodgates of the strongest construction to withstand the pressure of high tides. They form the east and west docks, capable of holding 1,000 vessels. The principal mouth of the Amstel divides the city into two parts. The land side was formerly surrounded by walls, now replaced by a ditch 30 yards wide lined with trees, which make a pleasant promenade. Some of the bastions are now occupied by windmills, the city relying for defence against attacks chiefly upon the facility with which the surrounding flat country can be flooded from the sea. Amsterdam stands upon flat, soft, marshy ground. The houses are built upon piles driven through this surface soil to the depth of 40 to 50 feet into a subsoil of clay or sand. The canals by which the city is intersected, and on which all heavy freights are transported, divide it into 90 islands, and are crossed by about 300 bridges. The city is about 10 miles in circumference. There are eight iron gates, each named after the town toward which it opens. The older portion of the city is irregularly built, and many of the streets are narrow and the houses poor. The newer portions are very handsome. The streets run in parallels along the former walls, and are consequently semicircular. In the centre of each is a canal, lined with clean paved quays, which are planted with trees. Three streets in this portion of the city are especially noteworthy for their length and breadth, and the elegance of the buildings which line them. These are the Heeren, Keizers, and Prinsen grachten.

Each is about 2 miles long and 220 feet broad. As with other streets, through the centre of each of these runs a canal. The principal shops of Amsterdam are in the Kalver straat, the Nieuwedijk, and the Warmoes straat. The bulk of the Jews live in true Ghetto style in the poorer grachten, or water streets, which are lively, particularly in the evening, but overcrowded and dirty. The houses of Amsterdam are built of brick, four, five, and six stories high, standing with their gables to the street; they are mostly entered by flights of steps in front, and are surmounted by forked chimney stacks. Many of the poorer people live in basements or cellars. Others live constantly upon the water, in apartments built upon the upper decks of their trading vessels. The most magnificent public edifice is the palace, formerly the city hall. It is built of stone, was begun in 1648,

and completed in 1655; rests upon 13,659 piles, driven 70 ft. into the ground; and is celebrated for its great hall or ball room, which is 111 ft. long, 52 ft. wide, and 90 ft. high, lined throughout with white Italian marble, and for its magnificent chime of bells, playing automatically every hour. The next most remarkable building is the Nieuwe Kerk (new church), lighted by 75 windows, many of which are beautifully painted. It contains the tomb of Admiral de Ruyter. The judiciary hall, opened in 1836, is among the finest structures in the city. Other buildings are the new town hall and the new exchange, founded in 1845; the arsenal, built on the island of Kattenburg; and the Oude Kerk (old church), founded in the 14th century, which contains the tombs of many of the Dutch admirals, and an organ said to be second only

The Palace of Amsterdam.

to that of Haarlem. Among the more recent fine public buildings is the palace of industry, established in 1864. Churches are numerous. The Calvinists have 10, the Catholics 16, and the evangelical Lutherans 2, one of which with surroundings is represented in our engraving. Various other denominations have several churches. Amsterdam has a great number of excellent charitable institutions, there being upward of 40 under the charge of particular denominations, and others belonging to the city. There are also various excellent educational institutions, some denominational in their character, others general. The *Athenaeum Illustre* has professorships of art, law, medicine, and theology, a school of anatomy, a botanic garden, and a free library. The city Latin school is a fine institution. There are besides medical and theological schools. The

royal academy of fine arts was founded in 1820. There is a music school, a naval school, a royal Dutch institution for science, literature, and fine arts, and another private scientific and artistic association, called *Felix Meritis*, which is patronized with great liberality, has 400 members, and is in a very flourishing condition. Finally, there is a museum of pictures, founded in 1798, containing a very large collection of the works of Dutch masters, and a remarkable collection of prints, contained in upward of 200 portfolios. The city is governed by a senate or council elected by the people, and a burgomaster appointed by the king.—Amsterdam is more noted as a trading than as a manufacturing town, though it has numerous manufactories of tobacco, soap, oil, cordage, canvas, steam engines and machinery, &c. There are also refineries of sugar and salt, glass works, brew-

eries, and distilleries; and ship-building is extensively carried on. The entrances and clearances of vessels in 1868 were about 3,000, with 850,000 tonnage; and the greater part of the foreign trade of Holland, which amounted in 1868 to an aggregate value of about \$150,000,000, passes through the port of Amsterdam. The chief articles of export are butter and cheese; other exports consist of products of the rich Dutch colonies, refined and raw sugar, coffee, spices, tin, oil, dyes, colors, fruit, vegetables, and flowers. The exports to Germany and England are the most prominent. By the Amstel, the Zuyder-Zee, and various canals, Amsterdam has water communication with all parts of Holland; and its railroad connections are also very extensive. The Zuyder-Zee, formerly the entrance to the port, long since became too shallow for the navigation of ocean vessels, and a canal called the Nieuwe Diep was built, admitting large ships, and connecting Amsterdam with the North sea at the Helder. The navigation of this long ship canal, with its large locks shutting out the ocean tides, having been found inconvenient and expensive, a colossal plan has been formed and nearly executed of connecting the harbor and docks by a short cut through the isthmus of North Holland, digging a ship canal through the immense sand hills protecting Holland at its western shore against the North sea. This canal, with its breakwater extending far out into the sea, will be second only in magnitude to the Suez canal. A part of the machinery that was used there has been transported to Amsterdam, and is employed in its construction. At the same time the Zuyder-Zee is to be made dry, and the inlet or arm, the Y, on which the city is situated, converted into dry land. Upon this a union railroad depot is to be constructed, where all the railroads will meet, and also the ocean vessels in the surrounding canals and docks.

AMUCK (Javanese, *amoak*, to kill). The running amuck is a Malay custom. The natives by a long-continued and excessive use of opium at length have their features sharpened, their skin drawn over their bones like parchment, and become entirely and ferociously mad. Armed with their formidable creese or dirk-knife, they rush in frenzy from their houses, sometimes naked, and leaping along the crowded streets, stab, bite, and curse every one who chances to be in their path. As soon as a person is seen in this state everybody in terror proclaims the news, and the cry of "Amuck" rouses the population like the cry of "Fire" or "Mad dog" in western cities. Every man snatches the first weapon that comes to hand, and follows the path of the common enemy. Long spears are, however, the favorite and more common weapon, and with these they pen the wretched maniac into a corner, and lance him to death as they would a tiger. Scores of persons are sometimes killed by one of these madmen before he can be checked.

AMULET (Ar. *hamalat*, a thing worn), a preservative against occult and mischievous influences. Amulets are made of various substances, and were first known, it is believed, among the Arabs. The early Christians made amulets of the supposed wood of the cross, or of ribbons with a text of Scripture written on them, and to this day the Roman Catholics call their little relics, &c., amulets. The idea that an amulet carried about the person has the power both of repelling and healing diseases still prevails in the mind of many persons. Even the celebrated Robert Boyle (who flourished in the latter half of the 17th century) does not hesitate to declare that he once experienced the efficacy of such an amulet in his own case. The anodyne necklace, made of beads from the roots of white briony, which is sometimes hung around the neck of an infant for teething purposes, is an instance of the still surviving confidence in the medical virtue of amulets. Many other examples might be given.

AMURATH, or *Murad*, the name of several Turkish sultans. **I.** Born in 1326, died June 15, 1389. He succeeded his father Orkhan in 1359 in the government of the Turkish dominions in Asia. The first act of his government was to put down an insurrection in Galatia, after which he turned his attention and his arms to Europe. Here he overran the country as far as the Balkan, and took Adrianople (1361), where he fixed his residence for a time, beautifying the city by the construction of a mosque and other public buildings. In 1365 a treaty of peace was concluded between the Ottomans and the republic of Ragusa, on the Adriatic, which put itself under the protection of Amurath. Pope Urban V., alarmed by the progress of the Ottomans, preached a crusade against them, but the Turks surprised the Christian forces by night near Adrianople and cut them to pieces (1368). The peace which Amurath had concluded with the Greeks, and which had been observed by him, being thus broken, he continued the war for several campaigns without any decided results, and went to Asia in 1371. Soon returning to Europe, he vanquished the princes of Servia and Bulgaria, and settled at Adrianople. During a peace of six years he employed himself in organizing his army, and formed the corps of spahis, instituting a system of military fiefs as the reward of their services. In this there was considerable analogy with the feudal system, and possibly he was assisted by renegade Christians in his plans. The Greek emperor, John Palæologus, seeing himself unable to cope with the new power arrayed against him, entered into friendly alliance with Amurath, and sent his son Theodore to his court to learn the art of war. The sons of the two emperors entered into a conspiracy against their fathers, and levied an army. Amurath advanced alone to the ranks of his rebellious son and ordered the soldiers to return to their duty. Unable to resist the mandate of their terrible ruler,

the men obeyed, and Amurath put his son Saudji to death (1375). In Asia Minor he had to contend with several insurrections. Lazarus, prince of Servia, in conjunction with Sisman, prince of Bulgaria, Amurath's father-in-law, renewed the effort for independence, and during Amurath's absence in Asia gained several advantages over his generals in Europe. The arrival of Amurath, however, turned the tide of victory, and at length he took Sisman prisoner, whom he deposed and confined. Lazarus, however, continued his resistance, and the armies met on the high plains of Kosovo, between Novi Bazar and Pristina. Amurath, under the influence of a dream that he had been assassinated, was at first unwilling to hazard an engagement, especially as his troops were far inferior in numbers to the Servians. But the counsels of his son, the fiery Bajazet, prevailed, and the signal for the engagement was given. After a bloody contest the Servians were totally defeated at all points, and Lazarus himself was taken prisoner. Amurath examined the field after the battle, and while congratulating his attendants upon the victory was struck by the hand of a wounded Servian. The wound was mortal, and Amurath's dream was accomplished. The Servian fell under the blows of the janizaries, but sold his life dearly. He proved to be Milosh Kobilovitch, son-in-law of Lazarus. Before expiring, Amurath, who is otherwise renowned as equally generous and wise, ordered the execution of Lazarus. **II.** Born about 1404, died Feb. 9, 1451. He was the son of Mohammed I., and in 1421 succeeded his father on the throne. He at once concluded an armistice for five years with Sigismund, king of Hungary and Bohemia, and emperor of Germany. Manuel, the Greek emperor, refused to conclude a peace unless Amurath gave his two brothers as hostages, failing which he threatened to set at liberty Mustapha, son of Bajazet Ilderim, the legitimate successor to the throne. Amurath refused, and the Greek admiral, Demetrius Lascaris, was at once sent to land Mustapha near Gallipoli, to which Demetrius laid siege. Mustapha himself advanced toward Adrianople with a constantly increasing army, and encountered Amurath's troops under Bajazet Pasha, who laid down their arms on his making himself known to them, and Bajazet was taken prisoner and put to death. Mustapha, however, was soon afterward betrayed to Amurath and executed. Manuel, now alarmed for himself, sent an embassy to the sultan to settle terms of peace. Amurath, however, was not to be appeased. He appeared with a powerful force before Constantinople in 1423, and increased his army by a proclamation of his intention to abandon the city and all the booty to the assailants. The assault was at length made, and the city was in deadly peril, when, according to Greek writers, a beautiful virgin dressed in a white robe appeared in mid air, and threw the Mohammedan army into such a panic that Amurath was obliged to retire. On the

death of Manuel (1425) a treaty was concluded with John Palaeologus, his successor, by which the Greeks consented to pay tribute to Amurath, and surrendered several towns on the Black sea and on the Strymon. The treaties of peace with Wallachia and the emperor Sigismund were also renewed. In 1429 Amurath made himself master of Thessalonica, and in 1431 of Janina. Notwithstanding the armistice between Amurath and Sigismund, their friendship was only superficial; and Amurath, who had suppressed the revolts of Caramania and Servia, and made satisfactory arrangements with other provinces of his growing empire, turned his attention to the politics of central Europe, and endeavored to influence the election of Casimir, son of the king of Poland, as king of Bohemia. Failing in this, he laid siege to Belgrade (1439), which was defended by the Hungarian warrior, John Hunyady. Amurath was repulsed, and the Ottoman arms now sustained a long series of reverses from the invincible Hunyady. Amurath at last purchased a 10 years' truce of the Hungarians by great sacrifices. The death of his son Aladdin, to whom Amurath was tenderly attached, now plunged him into such distress of mind that he abdicated in favor of his son Mohammed, who was only 14 years of age (1442), and retired to Magnesia, in Asia Minor. The Christians, in the belief that their opportunity had now arrived, broke the solemn peace, for which the papal legate gave them absolution, and poured into the Turkish dominions under the command of Ladislas, king of Poland and Hungary, and his general, Hunyady. Amurath was recalled from Magnesia, and forced to take the command of the army. Hoisting the treaty at the end of a lance, he encountered the Christians (1444) at Varna, on the Black sea. In a personal contest he dismounted Ladislas, whose head was cut off and displayed on a lance to his soldiers. Affrighted at the sight they fled, notwithstanding the efforts of Hunyady to restore the battle. Again Amurath sought retirement, and was again called out to put down a revolt of the janizaries. Hopeless of gratifying his wish for ease, he marched against Greece. After subduing the Morea, and putting it to tribute, he encountered stubborn resistance in Albania from the heroic George Castriota (Scanderbeg), who, with the assistance of the Venetians, was able to postpone for a time the fall of his native country. A new irruption of Hunyady into Servia compelled Amurath to retire from Greece, and a battle was again fought on the plains of Kosovo, in October, 1448, in which the Hungarian army, after a desperate defence of their entrenched camp for three days, was entirely routed with prodigious loss. Amurath did not long survive this crowning victory, dying suddenly of apoplexy, on an island near Adrianople. **III.** Born in 1545, succeeded his father, Selim II., in 1574, died Jan. 17, 1595. His first act was to put his five brothers to the bowstring. His reign

is signaled in Turkish history by the arrogance with which the Turks treated the representatives of the European powers. The ambassadors were compelled to observances of etiquette degrading to their sovereigns, and the agents of the embassies were subjected to personal indignity, the dragoman of France having been compelled to embrace Islamism. In the reign of Amurath III. the plague ravaged Turkey and Italy. The war with Austria was continued, and a war which had commenced with Persia was terminated in 1590 by a treaty which secured to the Porte the possession of Luristan, Georgia, Shirvan, Tabriz, and part of Azerbaijan. A depreciation of the coinage resulted in a revolt of the janizaries, who demanded the heads of two officers of state, whom they charged with having been the authors of the depreciation. This revolt extended itself throughout the Turkish empire, and laid the foundation for the disorder and insubordination which rendered the janizaries so celebrated. The war with Austria continued with varying success until the end of his reign. **IV.** Born in 1611, succeeded his uncle Mustapha, Sept. 1, 1623, at the age of 12, died Feb. 8, 1640. At the commencement of his reign the empire was in a state of the most deplorable disorder. The provinces were rent by insurrections and revolts; the capital convulsed by the constant mutinies of the janizaries, who were not to be pacified, save by an increase of pay or by the abandonment of some unfortunate vizier to their brutality; war was desolating the frontiers of the empire. Assuming the sceptre at so early an age, Amurath had little power to amend the state of his kingdom, but with experience came a vigor which was destined to make the hardest tremble. In 1638 he commenced the siege of Bagdad, which had long resisted the efforts of the ablest Turkish generals. On Dec. 24 the assault was made, and the city of the caliphs passed from the Persians to the Turks. The garrison of the citadel capitulated, but not evacuating the city at the hour promised, 30,000 Persians were massacred. Although in the early part of his reign Amurath had promulgated strict laws against the use of wine, he afterward abandoned himself to the most outrageous drunkenness; and his fits of delirious rage while intoxicated were so terrible that his people, his soldiers, and ministers all dreaded to enter his presence.

AMUSSAT, Jean Zuléma, a French surgeon, born at St. Maixent, department of Deux-Sèvres, Nov. 21, 1796, died May 14, 1856. He commenced his career as a sub-assistant surgeon in the French army, and afterward became assistant surgeon at the hospital of La Salpêtrière, under Esquirol, and prospector at the faculty of medicine of Paris. He invented and improved as many as 30 different surgical instruments, and was the first to show the importance of twisting a bleeding artery to arrest the hemorrhage, and also to point out the danger of phlebotomy from the admission of air into the veins

during an operation. His most important works are: *Recherches sur le système nerveux* (1825); *Tables synoptiques de la lithotripsie et de la cystotomie hypogastrique* (1832); *Recherches sur l'introduction de l'air dans les veines* (1832).

AMYDALOID, a rock containing almond-shaped cavities. The term is for the most part limited to rocks of the trap variety. The vesicular cavities in these, as in the lavas, are the result of the escape of gases, as the rocks cooled down from a melted state. Subsequently to their formation the cavities have generally become filled with some mineral, as calcareous spar, quartz, agate, chlorite, or a zeolite.

AMYL (Gr. *ἀμύλον*, starch), C_5H_{11} , the radical of amylic alcohol or potato spirit, a colorless liquid, with a somewhat aromatic odor, prepared by Frankland in 1849 by heating the iodide of amyl with an amalgam of zinc in sealed tubes for some hours at a temperature of from 320° to 356° F. It also occurs as an incidental product in the distillation of coal. As it doubles its molecular constitution whenever attempts are made to isolate it, the liquid described by Frankland is now commonly called diamyl, and the formula written $(C_5H_{11})_2$. Amyl, or rather diamyl, has the specific gravity of 0.77 at 60° F., boils at 311° F.; becomes thick at 22° F., but does not freeze; takes fire when heated and burns with a smoky flame; mixes in all proportions with alcohol, but not with water; is not acted upon by fuming sulphuric acid, but slowly attacked by nitric and nitro-sulphuric acid, and decomposed after long digestion with pentachloride of phosphorus. Amyl by itself has no use in the arts, but is interesting to the scientific chemist on account of the great number of substitution products that have been derived from it.—Nitrate of amyl is an inflammable liquid, lighter than water, and having an odor like very ripe pears. It produces in man, when inhaled in the dose of three or four drops, a sudden and violent acceleration of the pulse, with a peculiar flushing of the face. In animals it is capable of producing death. It may be regarded as a powerful general sedative, the peculiar action on man being due to a rapid relaxation of the muscular walls of the arterioles, giving rise to a suddenly diminished pressure of the blood in the arteries and heart. Its therapeutic applications are not yet extensive, but it has been used with good effect in angina pectoris, and some other diseases of a supposed spasmodic character.

AMYLENE, a transparent, colorless, thin liquid, with the odor of decaying cabbage, boiling at 102° F., vapor density 2.43, sp. gr. 0.65. It is produced by the dehydration of amylic alcohol by sulphuric acid or phosphoric acid. It was discovered in 1844 by M. Balard, by heating a solution of chloride of zinc with amylic alcohol or fusel oil, and in a compound of 5 atoms of carbon with 10 of hydrogen. In its preparation a concentrated aqueous solution of chloride of zinc is heated to 266° F. with an equal

volume of amylic alcohol, and the product distilled from a water bath over caustic potash and repeatedly rectified. It is very volatile, mixes with alcohol and ether, burns with a beautiful white flame, combines directly and energetically with bromine, the hydracids, and chloride of sulphur, and its vapor is rapidly absorbed by sulphuric anhydride and perchloride of antimony. Amylene is the third homologue of olefiant gas or ethylene, and like the latter is the starting point of a multitude of compounds which are derived from it by addition, substitution, or subtraction. An attempt was made to substitute it for chloroform as an anæsthetic in surgical operations; but this use has been abandoned, as its employment has in a few cases led to fatal results.

AMYNTAS, the name of three Macedonian kings. **I.** The son and successor of Alceat, reigned from 537 to about 498 B. C. During his reign Megabazus, the general of Darius, sent ambassadors to demand from Macedonia earth and water, the tokens of submission. The weak Amyntas gave them at once. He even invited the Persian envoys to a magnificent banquet, and when, heated with wine, they brutally ordered him to give up to them his wives and daughters, he would have had the baseness to obey; but his son Alexander disguised as women several pages of the court, who, when brought to the Persians, murdered them with their daggers. **II.** Nephew of Perdicas II., died in 369 B. C. He actually inherited only Upper Macedonia, but after contesting the sovereignty of the whole country first with his brother, who defeated him with the aid of foreign allies, and afterward with the usurper Pausanias, he became king of all Macedonia in 393. He was again driven from his throne by Argeus, son of Pausanias, and only recovered it with the help of the Thessalians. He entered into a lasting alliance with Sparta. **III.** Grandson of the preceding, succeeded, when yet an infant, his father Perdicas III., 360 B. C., but was in the following year deposed by his uncle Philip II., and put to death on the accession of the latter's son, Alexander the Great, who charged him with conspiring against his life (336).

AMYOT, Jacques, a French author, bishop of Auxerre, born at Melun, Oct. 30, 1513, died at Auxerre, Feb. 6, 1593. After many arduous struggles with poverty and obscurity, he succeeded in acquiring some reputation as a teacher; and through the patronage of the sister of Francis I., Margaret of Berry, he was made professor of Greek and Latin in the university of Paris. Subsequently he obtained the abbacy of Belozane, and visited Rome to gather materials for the translation of Plutarch and other Greek writers, and took part in the council of Trent. On his return to France he became tutor of Henry II.'s two younger sons, the future kings Charles IX. and Henry III., under the former of whom he was raised to the offices of grand almoner and curator of the

Paris university, and ultimately to the bishopric of Auxerre. The most celebrated of his works, which chiefly consist of translations, is the version of Plutarch.

AMYRAUT, Moïse, a French Calvinist theologian, born in 1596, died in July, 1664, at Bourgueil, in the province of Anjou. He was educated at Saumur, where he was afterward a professor of divinity. By his talents and moderation he soon acquired reputation and influence. In 1631 he attended the synod of Charenton, and was commissioned to present to the king a remonstrance against the infraction of the edicts of pacification. In fulfilling this mission he procured the abrogation of the humiliating requirement that Protestant deputies should address the king only on their knees. He endeavored to bring about a complete union between the various Protestant churches, which he advocated especially in a Latin tract, *De Seccessione ab Ecclesia Romana, deque Pace inter Evangelicos in Negotio Religionis instituenda*. The favor and respect with which he was treated by the heads of the French government, Richelieu and Mazarin, are to be ascribed to his opinions concerning the power of princes; he publicly maintained on several occasions the doctrine of implicit obedience to the sovereign authority. Among his numerous writings, now nearly forgotten, though popular in their time, are treatises on Christian morals, on the natural laws of marriage, against indifference, and against the Millenarists.

ANA, as a prefix, a Greek word signifying over again, against, and the like. Its use is exemplified in Anabaptist, anachronism, and analysis. As a suffix, it is the Latin termination of the neuter plural of an adjective of three terminations; thus *Ciceroniana* would be the matters of any sort appertaining to Cicero. In the literature of the modern European nations, it alludes to the collections of the sayings or anecdotes of celebrated wits. The first collection of this kind was the *Scaligeriana*, published at the Hague in 1666, by Vossius, in Latin. The next of the ana was the *Perroniana*, in French, being notes of the conversations of Cardinal Duperron (1669). *Menagiana* and *Thuana* are also celebrated collections in French. French literature of the 17th century is particularly rich in this department. The ana mania lasted about half a century. In English, the "Walpolliana" is the best. German literature is not rich in personal memoirs; the *Taubmaniana* is the most famous, and we have also the *Melancthoniana*. In England, the records of the prize ring are called "Fistiana" and "Boxiana." American literature does not much affect this species of title.

ANABAPTISTS (Gr. ἀναβαπτιστης, a rebaptizer), a name sometimes applied to all those sects of modern times of which rebaptism has been a distinguishing mark. The justice of the appellation has never been acknowledged by those to whom it has been applied. In receiving converts to their communion, they administered

baptism, not as repeating the sacred rite, but as a valid baptism, in place of one which was imperfect or void. Thus, the Baptists repel the name Anabaptists, not, as some suppose, for the mere purpose of repudiating an alleged connection with the fanatics of the reformation, but because it does not represent correctly their practice. They baptize, as they allege, according to the original institution of the rite, and therefore claim to be Baptists; they never repeat baptism in the case of any who, in their judgment, have been so baptized; and they therefore deny that they are Anabaptists. It may be doubted whether the word, as now applied to Baptists, is not always intended as a reproach; certainly it should be excluded in that application from respectable modern literature, as giving an unnecessary offence.—The title belongs historically to large classes of people who sprung up in various countries of Europe during the period of the reformation. Though applied to them against their remonstrances, it has become fixed in literature as a historical term, and is too convenient for practical purposes to be expelled by any considerations of critical justice. Whether these various classes agreed or not in things more essential; whether they were furious and fanatical, or gentle and pious; whether setting up mock kingdoms by force of arms, or conscientiously abstaining from the use of arms altogether, they were alike in the visible thing of repeating baptism, and hence were designated by a common name, and too often visited with common penalties and maledictions. It is the business of the historian to discriminate between these classes, to look beyond names for historical facts, and to redeem from the reproach of many generations great numbers of people whose faith was in essential harmony with the faith of Protestantism, whose lives were pure, and whose deaths were a rare and honorable martyrdom. In this historical discrimination something has been already effected. Illustrations generally accessible may be found in Burnet's "History of the Reformation in England," Brandt's "History of the Reformation in the Netherlands," Mosheim's "Institutes of Ecclesiastical History," and especially in the "Dutch Martyrology," published by the Hanserd Knollys society, London, under the editorial care of Edward B. Underhill.—Precisely when or where the Anabaptists of the reformation period first appeared, whether in Germany or Switzerland, it is difficult if not impossible to determine. They sprung up like rank vegetation, under sudden and refreshing rains, after drought and sterility. The solution of the problem is found in the fact that the seeds were in the soil. The better classes of them claimed a descent from the Waldenses, the Wycliffites, and the Hussites, who had struggled for a church separated from the world and distinguished by the holiness of its members. Consciously or unconsciously, ideas like these must have been working in the

minds of multitudes in various countries. When, therefore, the reformation came, opening the Bible to the people, announcing its revelations as the highest law, and inviting the human mind to freedom of thought, these principles acquired sudden and prodigious force. Ardent minds, bent in the direction of a primitive Christianity, and of a social order corresponding thereto, were dissatisfied with the partial reformation which contented Luther and Zwingli, and demanded more. This demand, sharpened by discussion, became a popular movement, and, pushed to its last development, took the opposite directions, on the one hand, of a wild, ungovernable, and licentious fanaticism, subversive of all social order, and on the other, of a mystical though sincere and genuine piety, characterized by some harmless eccentricities of faith and by separation from the world. These parties, so diverse in character and tendencies, went under the common name of Anabaptists, because they were distinguished by the common, visible badge of rebaptism.—The usual references in illustration of the character of the furious Anabaptists are the following: In 1521 they made their appearance at Zwickau, and, accepting as their leader Thomas Münzer, took part in the peasants' war, and shared its sanguinary results. Münzer and his associates are represented as having claimed a divine commission not only to establish a community of holy persons, but also to extirpate magistrates by the sword. He excited his followers to revolt against the civil authorities, and assured them of the immediate deliverance of Christendom from the grievous oppressions of its rulers. They were totally defeated, May 15, 1525, near Mühlhausen, and the leaders were put to death. Itinerant prophets still, however, spread the principles of the sect. They declaimed against the wickedness of the times, and demanded a community of saints, without distinction of rank or office. They claimed an internal light, which was of more value than learning in interpreting divine revelation. No Christian might exercise the functions of a magistrate or take an oath. Property was to be shared in common among the faithful. In 1533 they began to concentrate their operations at Münster. John Matthias of Haarlem and John Beccold of Leyden were their leaders. They had gained over to their cause Rothmann, the preacher who introduced the reformation into that city, and Knipperdolling, a leading citizen. Seizing the arsenal and the senate house, they placed Matthias at the head of affairs, and his authority became arbitrary and complete. The inhabitants were trained to military duty, the fortifications were strengthened, and the faithful were invited to come from every quarter to aid the struggles and share the triumphs of Mount Zion, from which they were to proceed to the conquest of the world. Count Waldeck, prince and bishop of Münster, surrounded the city with an army. Matthias sallied out and

gained signal advantages. His fanaticism rose with his success, and, issuing forth again with only 30 followers relying on their spiritual pretensions, was with all of them put to death. John Boccold was now raised to the throne of David, in obedience to divine commands made known in visions. He wore a crown, clothed himself in purple, coined money, and appointed judges. But the fanaticism, when it had reached the height of spiritual folly, passed by an easy transition to licence and sensuality. The obligations of matrimony were declared invasive of spiritual liberty, and freedom of divorce and licentiousness followed. King John himself multiplied his wives, honoring, however, one of them only as his queen. The example of the monarch was not lost upon the people, and the name of Münster during the reign of the Anabaptists has passed to history as the synonyme of unbridled and indecent lust. The city was taken June 24, 1535, after a brave defence, in which Rothmann was slain. John Boccold, and Knipperdolling and Krechting, leading associates, were tortured with red-hot pincers, and then hung up in iron cages, which are still preserved in Münster. Thus in 15 months perished the kingdom of the Anabaptists. Even now, however, the delusion did not cease. It subsided indeed into its more spiritual character, and its excesses were chiefly individual and local. But the fanaticism of this class of Anabaptists remained the reproach of the reformation, and the terror of civil society.—There was another class of Anabaptists, widely different from those who have been described. In some instances, undoubtedly, when the former class fell back upon their purely spiritual views, the two parties coalesced. Brandt refers to an instance in which the moderate were brought into difficulty by being found in such association with the fanatical. The distinction, however, is real, and may be traced. It is a mistake to suppose that the rejection of infant baptism during the reformation was found among the unlearned only. Melancthon, Zwingli, and Ecolampadius were all troubled by the questions which arose respecting the adjustment of this rite to the personal faith required by Protestantism. Some of those who became leaders of the Anabaptists were the associates and equals of these reformers. Mantz, Grebel, and Hulmeyer were men of learning—the last of great genius and eloquence. Mantz had been the friend and fellow student of Zwingli, and was an early martyr in the cause of the Anabaptists, Zwingli himself pronouncing his sentence in the words, “*Qui iterum mergit, mergatur.*” The persecution of such men and their followers in Switzerland shocked the moderate of all parties. In expressing his views of this persecution, Erasmus pays a tribute to the character of the sufferers in these words: “A people against whom there is very little to be said, and concerning whom we are assured there are many who have been reformed from the worst to the

best lives; and though, perhaps, they may foolishly err in certain opinions, yet have they never stormed towns nor churches, nor entered into any combinations against the authority of the magistrate, nor driven anybody from his government or estate.” These people, so persecuted, demanded a church composed of spiritual persons, introduced into it by a voluntary baptism. They demanded likewise the separation of the church from the state, and the non-interference of the magistrate in matters of religion. Anabaptists of the same class were found in the Netherlands in large numbers. The record of their sufferings, their martyrs multiplied by thousands, furnishes a melancholy and affecting chapter in human history. William of Orange, founder of the Dutch republic, was sustained in the gloomiest hours of his struggles by their sympathy and aid, and has left his testimony to their loyalty, industry, and virtue. That great prince, however importuned, steadfastly refused to persecute them. The same class were found in England during the reign of Edward VI., and Burnet declares that books, not flames, were used in reply to their arguments.—One of the doctrinal peculiarities of the Anabaptists, which seems to have been almost universal among them, related to the origin of the human nature of Christ. They denied that he took his flesh of Mary, explaining his incarnation by a higher miracle. Doubts have arisen, on the one hand, as to whether they believed in the reality of his human nature, and on the other, as to whether they believed him to be a divine person. The records of the examination of some of them before the courts ought to remove all questions of this kind. They believed fully in his complete humanity, and their answers show that their questionings in regard to the origin of his human nature did not necessarily imply any departure from the common views of his divinity. Menno Simonis became their chief leader, and the instrument of their organization into a recognized body of Protestant Christians. Mennonites and Anabaptists have from his time been interchangeable terms, and the communities so called have descended to the present age. (See MENNO SIMONIS, and MENNONITES.)

ANABAS SCANDENS (Cuv.), an acanthopterygious fish, of the family of *labyrinthibranchida*, and the only species of the genus. This family, which has been known from remote antiquity, is remarkable for the peculiar structure of some of the pharyngeal bones and for the serrations of the gill covers. The palate is toothless; the jaw teeth are villiform, the outer ones the strongest; the lower is toothless in front, but far back among the three superior pharyngeals the teeth are crowded, conical, and large. The head is round and wide, and its scales, as well as those of the body, are large, hard, and strong; the dorsal and anal fins are of nearly equal height; the branchiostegal rays are six. The inferior and three posterior upper pharyngeals are of the usual form, and provi-

ded with teeth; but the two other upper pharyngeals on each side are dilated into thin and convoluted laminae, capable of retaining a considerable amount of water; this labyrinth communicates with the gills by a small opening which may be entirely closed. The water enters this cavity every time the fish opens its mouth, and may be retained for a considerable period. A fish dies out of water, not from immediate want of oxygen, but because the gills become dry and improper for its transmission. The anabas can live many hours and perhaps days on the land, as the water contained in its pharyngeal receptacle trickles slowly over the gills and keeps them moist at the will of the animal, which leaves the rivers and pools, and crawls by means of its fins and tail considerable distances. Another peculiarity of this fish is the number of sharp spines which project from the edge of the operculum and suboperculum, the latter being uncommonly movable. The specific name is derived from its alleged habit of climbing trees, which it is said to do by fixing its opercular spines in the bark, flexing its tail, and fastening the spines of the anal fin; then detaching the head, it throws itself forward, to recommence the planting of the anal spines. It certainly moves on land in this way, and may perhaps ascend low trees, though this is denied by some writers. It inhabits the streams and pools of India and the Indian islands, living principally on aquatic insects; it is used as food, though small and full of bones; it grows from 6 to 10 inches long. It is brought alive to the Calcutta markets from a distance of over 150 miles; from its being found at a great distance from water, the natives believe that it falls from the heavens.

ANABASIS, a Greek word signifying originally ascension, then a campaign or march from a lower to a superior region; for example, from the shores of a sea to the interior of a country. In this signification the word forms the title to two historical works of antiquity: the one, by Xenophon, describing the anabasis or campaign of Cyrus the Younger against his brother Artaxerxes II., and the celebrated retreat of the 10,000 Greeks, auxiliaries of Cyrus, from the battlefield of Cunaxa, where that prince perished, to the shores of the Euxine; and the other by Arrian, relating the anabasis or campaigns of Alexander the Great.

ANABLEPS, a genus of soft-rayed fishes of the carp family (*Cyprinidae*), so named because the division of the cornea and iris by transverse ligaments gives the appearance of double eyes, from the dumb-bell-shaped pupil. The lens, retina, and vitreous humor are single. As one half of each eye apparently looks upward and the other half downward, they have been popularly called four-eyed fishes. The *A. Gronovii* or *trophthalmus*, of Surinam and Cuyuni rivers, is about 10 inches long, with a cylindrical body and strong scales, flattened head, and blunt snout with the upper jaw the longer. This genus is also viviparous, but the vascular

adhesion of the embryonic membranes is ruptured long before the birth of the young, instead of at the time of exclusion as in mammals; the gestation is almost wholly ovarian. (See FISHERS.)

ANACHARSIS, a Scythian philosopher who made his appearance at Athens in the early part of the 6th century B. C. He became very intimate with Solon, and was so esteemed for his virtue, learning, and sagacity, that some ranked him among the seven wise men. He was made a citizen of Athens, and is said to have been even initiated into the Eleusinian mysteries. According to Herodotus, he was killed by his brother after his return to his native country. Many of the sayings of Anacharsis have been preserved by Diogenes Laërtius, Athenæus, and other ancient writers.

ANACLETUS. I. A saint and pope of the Roman church, according to some, the second after St. Peter, and a martyr under Domitian in 91; according to others, martyred about 109, having succeeded Clement I. as the fifth bishop of Rome. **II.** An anti-pope, whose original name was Peter de Leon. He was said to be of Jewish descent, was born in Italy, and educated at the university of Paris. He entered the order of Cluny, and was afterward cardinal and legate of Pope Calixtus II. both in England and France. He was elected pope in 1130 by a portion of the cardinals in opposition to Innocent II., and was sustained by the Romans, Milanese, and Sicilians. In spite of the arms of the emperor Lothaire and the opposition of other sovereigns and of the clergy generally, Anacletus maintained himself at Rome till his death, Jan. 7, 1138.

ANACONDA (*Eunectes murinus*, Wagler), a large serpent of the boa family, found in most parts of intertropical America. The genus *boa*, which contains the large American serpents, has been made to include many species which do not be-

Anaconda (*Eunectes murinus*).

long to it, among others the anaconda; and we find accordingly this species named *boa scytale*, *boa murina*, *boa gigas*, and *boa aquatica*, by various authors. The genus *eunectes* may be distinguished from all others of the boa family by the nostrils opening at the upper part of the end of the muzzle, and looking directly upward; this peculiarity, added to their very small size, the little space between them, and

their crescentic form, which allows them to be completely shut, indicates the aquatic habits which we know characterize the anaconda. Other generic characters are the three plates which surround the nostrils, the plates which cover the anterior half of the top of the head and the scales which cover it posteriorly, the flat and smooth scales of the body, and the undivided plates on the under surface of the tail. The head is comparatively small, conical, very flat below, and truncated in front; the body is considerably larger in the middle than at either extremity; the tail, less prehensile than in the boas, forms about one sixth of the total length. The eyes, which are small, are so placed that the animal can see at the same time objects above and before it, a provision common to all water serpents. The mouth is perfectly straight, and armed with strong teeth gradually diminishing in size in the four series; the number is 16 on each side in each jaw, 5 on the palate, and 10 on the pterygoid bones. The scales of the body are lozenge-shaped, and nearly of the same size, except those of the sides, which are two or three times larger than the rest; on the trunk there are about 60 longitudinal and 375 transverse rows; on the tail there are over 80 transverse and about 36 longitudinal rows. The plates or scutellæ of the abdominal region are very narrow, and about 250 in number, and of the tail from 60 to 73. The colors are simpler than in the boas, being blackish green above in the adults, and olive brown in the young; on the temples, between two lines of pure black, is a wide yellow band extending obliquely from the eye to behind the angle of the mouth; the back and tail present large oval disks of deep black, disposed in two series alternating with each other, and occasionally coalescing; along each side is a single or double row of black rings contrasting finely with the yellow ground color; the color beneath is ochre yellow with black quadrangular spots, isolated or confluent. The anaconda is the largest serpent of America, and is only equalled in size by some of the pythons of the old world; it is occasionally seen in museums 20 feet long, and it probably attains a considerably larger size, though the accounts of travellers are generally much exaggerated in this respect. The Guianas and Brazil are the favorite and perhaps the exclusive resorts of the anaconda. It lives mostly in the water, and is fond of shallow places, where it remains with all but the head submerged watching for its prey; it swims rapidly, in an eel-like manner, and can pass a long time beneath the surface; it is occasionally seen floating lazily with the current; it is also in the habit of stretching itself on the sand or on the rocks, on a river's bank, or along the trunk of a fallen tree, where it lies in wait for animals which come to drink. Its ordinary food consists of agoutis, small rodents, iguanas, fish, and occasionally a monkey, sloth, or ant-eater; it crushes its prey in its strong folds, and, seizing it with its teeth, swal-

lows it very slowly, head first. The time of impregnation is the winter months, when the natives attack it with guns, arrows, and even clubs; it is sluggish in its motions on land, and timid, and not at all feared; it is very tenacious of life. The natives use the skin for shoes and bags, the fat for the purposes of oil, and the flesh for food. It is ovoviviparous. Only one species of the genus is described.

ANACREON, a Greek lyric poet, born at Teos in Ionia about 561 B. C. When that city was taken by the Persians, about 540 B. C., he emigrated to Abdera in Thrace, whence he afterward went to Samos, and spent several years at the court of Polyocrates. On the death of Polyocrates he was invited to Athens by the tyrant Hipparchus, who sent a vessel for him. Here he formed an intimacy with Simonides and other poets. He left Athens probably on the murder of Hipparchus in 514, and died in the 85th year of his age, but the place of his death is uncertain. He is said to have been cloaked by a grape stone. We possess only a few genuine fragments of the poems of Anacreon. His favorite themes were love and wine; his distinguishing characteristics licentiousness, gracefulness, and fervor. The best editions are by Fischer (3d ed., Leipsic, 1793) and Mehlor (Glogau, 1825), and of the separate fragments that of Bergk (Leipsic, 1834).

ANADYOMENE (Gr., *emerging*), a surname given to a picture of Venus rising from the ocean. Apelles was the first who painted her in this posture as she rose from the sea, and was drying her hair with her hands. This picture was bought by the inhabitants of the island of Cos, and put in their temple of Æsculapius. The emperor Augustus bought it of them for the remission of 100 talents tribute, took it to Rome, and placed it in the temple of Venus Genitrix. In Nero's time it was nearly washed out, and was repaired.

ANADYR, or *Anadir*. **I.** An extensive gulf or sea of Asia, at the N. E. extremity of Siberia, lying between Cape St. Thaddee and Cape Tehukotskoi, of late years much resorted to for whales. **II.** A river of Siberia, having its source in Lake Yoanko in the Stanovoi mountains, about lat. 66° 30' N., lon. 173° E. It traverses the central portions of the Tehukethi country in N. E. Siberia, flows first W., then E., and after a course of about 500 m. falls into an inlet of the gulf of Anadyr. The country through which it passes is rocky and barren, and covered with snow about nine months in the year.

ANEMIA. See BRAIN, DISEASES OF THE, and CHLOROSIS.

ANÆSTHETICS (Gr. *án*, privative, and *αισθάνομαι*, I feel), substances which can produce a general or partial suspension of nervous sensibility. In the common acceptance of the term should be included all drugs which have the faculty of so acting upon the brain that this effect can be caused; for instance, all the forms of narcotics and diffusible stimulants.

But by general consent this title is now confined to the most volatile forms of chemical agents which can produce the effect when inhaled or applied externally, and the effects of which are transitory; the terms narcotization and coma being applied where a long-continued effect is caused by other agents. The general action of all anæsthetic agents is through the medium of the blood, into which they are taken either from the lungs, the stomach, or by the skin, and carried by the circulation to the brain, where they produce a profound but transient state of intoxication. Anæsthesia is said to be either general or local; general, when all power of sensibility is suspended; local, when only a particular part of the body is affected, the brain and the rest of the system remaining as ordinarily. Loss of sensation in restricted portions of the body has been attempted in various ways, as by long pressure upon the nervous trunks leading to the part, first put in operation by Ambroise Paré, afterward adopted by Dr. Moore, about 1784; the application of carbonic acid gas, recommended by Dr. Hickman in 1823, a procedure which was revived by the late Dr. Simpson; the application of the various ethers, especially chloroform; and by a true freezing of the part, as recommended by Dr. James Arnott of London, who employed for the purpose a mixture of pounded ice and common salt enclosed in a muslin bag. The most useful method has been found to be the employment of ether spray, directed in a continuous stream upon the part by means of an atomizing apparatus. Various anæsthetic agents have been employed at different times—the several kinds of ethers, nitric, acetic, sulphuric, &c., protoxide of nitrogen (“laughing gas”), aldehyde, olefiant gas, naphtha, carburetted hydrogen, Dutch liquid, benzoin, chloroform, and amylene, a substance introduced by Dr. Snow of London; but none of them have proved so successful, or are now so generally used, as sulphuric ether and chloroform. This latter substance was discovered in 1831, but its chemical composition was not accurately known till 1834. (See CHLOROFORM.) Its use for the same purpose as sulphuric ether was first proposed by Dr. J. Y. Simpson of Edinburgh, in 1847. The advantages claimed for it over ether are the smallness of the dose required, a more perfect action, less depression when the heart or lungs are diseased, a more rapid effect, less disgust to the patient during inhalation, absence of persistent odor, and lastly, that it is cheaper. But as unfortunately it has happened that several deaths have occurred from its use, it cannot be looked upon as so safe an agent as ether, from the use of which, no matter in how large quantities or how carelessly, not one death has yet been reported. The benumbing of the nerves of sensation by the administration of narcotic drugs has been practised for many years, and, as records show, was known to the ancients; but with the exception of certain traditions as re-

gards the use in the East of the mandrake (*atropa mandragora*) and hashish (*cannabis Indica*) in the form of vapor for this purpose, we have no proofs that anæsthetic inhalation was ever employed. Richard Pearson recommended the inhalation of sulphuric ether for asthma, &c., in 1795; and in 1816 Nysten described an instrument for its use. In Sir Humphry Davy’s “Researches concerning Nitrous Oxide,” published in 1800, is this remark: “As nitrous oxide in its extensive operation seems capable of destroying physical pain, it will probably be used with advantage during surgical operations in which no great effusion of blood takes place.” Dr. J. C. Warren of Boston prescribed ethereal inhalation for the relief of pulmonary inflammation in 1805, and Mr. Wesley Smead of Cincinnati published an article on this treatment in 1822. The power of the ethers to produce insensibility was mentioned by Godman in 1822, Mitchell in 1832, Prof. Samuel Jackson in 1833, and Wood and Bache in 1833. But its application as an agent for the relief of pain during surgical operations was first publicly made at the Massachusetts general hospital in Boston, Oct. 16, 1846, by Dr. W. T. G. Morton of that city, who subsequently secured a patent for the use of the article under the name of “letheon.” On Jan. 2 of the next year a new claimant for the discovery came before the public, in the person of Dr. Charles T. Jackson of the same city; and still later the same claim was advanced in behalf of Dr. Horace Wells of Hartford. (See JACKSON, MORTON, and WELLS.)—The objects gained by the administration of anæsthetics are various, according as we have to do with surgery, midwifery, or medicine. In surgery: 1. A protracted and careful examination, and consequently more accurate diagnosis, can be made in many cases of disease and injury, where the intense pain caused by the examination prevents the manipulation of the surgeon, as in fractures, dislocations, and stone. 2. From the total relaxation which the muscles receive under a full dose, the reduction of many forms of dislocation, hernia, &c., is facilitated. 3. In military service, under its influence, men can be removed to a distance where the operation can be conveniently performed, instead of as formerly being obliged to operate upon the field of battle or in places otherwise unfavorable. 4. The general use of many forms of remedial operation is extended, which otherwise are attended with such exquisite agony that they were rarely resorted to unless from most extreme necessity, as for instance the application of the actual cautery and moxas. 5. Many operations can now be performed for the relief of long-continued disease, or after injury, which before would have been hazardous, owing to the depressed or feeble state of the patient. 6. Many delicate operations can now be easily performed where perfect quiet is demanded of the patient, and which can hardly be afforded by any amount of exercise of the will, as in operations upon the eye, dis-

section of nerves, or the taking up of arteries. 7. Patients will now apply earlier than heretofore for relief in surgical diseases, the dread of the surgeon's knife often having induced them to postpone it until the case became almost hopeless. 8. The mortality from operations has materially decreased, for it is well known that pain has a serious tendency to depress the nervous system and produce death from exhaustion.—In midwifery: 1. In addition to preserving the mother from the pain always incident to parturition, we have the power of preserving her strength unimpaired when the labor is long continued or especially severe. 2. In all cases of instrumental labor or those requiring manual assistance, the aid can be afforded with greater ease to the accoucheur and more safety and less accompanying suffering to the mother. 3. Many cases in doubt in diagnosis can be more correctly solved. 4. From the relaxation of the muscular fibres, the exit of the child through the uterine neck or the vaginal passage, when they are rigid, is facilitated. 5. Anæsthetics have the power of keeping in abeyance and reducing the violence of one of the worst complications of labor, puerperal convulsions. 6. The recovery of the patient after labor is assisted, and the chances of subsequent dangers lessened.—In medicine: 1. As a relief from severe or exhausting pain in disease, as from toothache, passage of calculi, or neuralgia. 2. As a narcotic in mania, delirium tremens, excitement, or wakefulness from any cause. 3. As an antispasmodic for cholera, hysteria, asthma, convulsions, &c. They have also been employed in the treatment of many inflammatory diseases, fevers, &c. They are found very useful in the detection of feigned diseases, as affected paralysis, dumbness, or contraction of limbs. They have been sometimes employed for nefarious purposes in cases of violence, where a struggle or noise was feared.—The first effects of all anæsthetics, or when they are taken in small quantities, is exhilarating and intoxicating as from any diffusible stimulant, evidenced by bursts of laughter, hysterical weeping, or loud unmeaning talk. When long continued or in large doses, there ensues a general feeling of warmth, extra power, and excitement generally, first felt in the extremities, soon followed by a prickling benumbed sensation, with confusion of ideas, noises in the ears, usually compared to the vibration of an engine from one side of the head to the other, and flashes of light before the eyes. This is soon followed by loss of sensation and voluntary motion, and total coma. The patient is generally observed to become a little flushed in the face, the veins of the forehead turgid, the eyes suffused and staring open, and the pupils dilated. The pulse is generally increased at the commencement of inhalation, but becomes decreased often lower than natural when the system is fully under the influence, which is the time chosen for the performance of all great surgical operations. The

respiration, which is slightly quickened at first, becomes slower and deeper in the somnific state. The temperature of the body remains generally of the ordinary standard, but becomes slightly reduced when the influence is long continued. The effects of the anæsthetic generally disappear soon after the administration is discontinued, and the patient returns to consciousness with merely a slight tendency to sleep and dizziness, and with no recollection of anything which has happened during the inhalation. Sometimes, however, the recovery is attended with nausea or vomiting, which most often happens when the drug is taken on a full stomach; for this reason it should not usually be given until several hours after a meal has been eaten. No person has yet been found to withstand the influence, but the effect is seen much sooner and more quietly in some than in others. Anæsthetics should not generally be used in diseases of the heart or brain, or when there is excessive degeneration of the lungs. When, from an over-dose or the inattention of the giver, the patient seems likely to sink, and respiration is suspended, the vapor should be removed from the mouth at once, the patient laid in a reclining position, free access of air allowed, cold water dashed upon the chest and face, and, if necessary, artificial respiration made, sinapisms placed on the feet, and galvanism used.—Many instruments have been devised for inhalation, but, as often happens, the simplest means is usually the best. The most advisable plan for administering is to fold a coarse towel into the form of a small cone, and place in the bottom a small sponge containing the liquid. At the commencement the sponge should be held at a small distance from the mouth, and the patient be directed to inhale by deep and long-continued inspirations, notwithstanding the cough. As he gets more and more under the influence, it should be approached to the face, but it is imperatively necessary that there should be a free admission of atmospheric air. Particular attention should be paid to the condition of the pulse. It is now generally conceded that chloroform is much more dangerous to life than ether. Ether should therefore be employed in preference, unless special circumstances make it imperative to select chloroform as the anæsthetic agent. If chloroform be used, it should be remembered that its vapor is heavier than the air, and consequently sinks; care should also be taken to guard the skin from its irritating properties by smearing slightly with oil or glycerine. If ether be used, care should be taken not to have any lighted candles or gas jets in the neighborhood of the patient, as the vapor of ether is exceedingly inflammable, and very serious consequences might result from its accidentally taking fire. The ratio of power of ether and chloroform is considered as about 8 to 1 in favor of the latter, this producing its effect in from 30 to 60 seconds, the former on an average in from 3 to 4 minutes. The dose of chloroform is from 30 drops to 1 oz.; that

of ether is of almost any quantity, as much as two quarts having been employed in some long-continued and severe operations.

ANAGNI (anc. *Anagnia*), a town of Italy, about 40 m. S. E. of Rome; pop. about 7,500. Anagnia was one of the most ancient cities of Latium, the capital of the Hernici, and an early antagonist of Rome. It is the residence of some of the most powerful families of Italy, and it has given birth to several Roman pontiffs, among others to Gregory IX., Alexander IV., and Boniface VIII.

ANAGRAM (Gr. *ἀνά*, backward, and *γράμμα*, letter), the transposition of the letters forming a word or sentence into a new word or sentence having some bearing upon the subject of the former one; as, *Honor est a Nilo*, formed from the letters in the name of Horatio Nelson. To make a true anagram, every letter of the original words must be retained in the transposition, and no new one must be added. In ancient times anagrams were regarded as prophetic, or as embodying a direction to the man on whose name they were made; it is said that Pierre de St. Louis became a Carmelite monk on finding that his name, Ludovicus Bartelemi, could be transposed into *Carmelo se devolret*. Satirical anagrams were very common in the 16th and 17th centuries; Camden, the English historian, devoted a treatise to them, and many of the most learned men spent their leisure in making them upon the names of their contemporaries. Perhaps the best anagram ever made is the one which transposes Pontius Pilate's question to Christ—*Quid est veritas?* (What is the truth?)—into the answer, *Est vir qui adest* (It is the man who is before you). The following are a few excellent anagrams; Arthur Wellesley, duke of Wellington—"Let well-foiled Gaul secure thy renown." Napoleon Bonaparte—"No, appear not at Elba." Louis Napoleon Bonaparte—"Arouse, Albion; an open plot." For some curious anagrams, and their history, see the introduction to "Macaronic Poetry," by James Appleton Morgan (New York, 1872).

ANAHUAC, an aboriginal name, signifying, in the Nahuatl or ancient Mexican language, by or near the water; from *atl*, water, and *nahuac*, near. The name has come to be applied specifically to the valley, or rather the plateau of the city of Mexico, although in the early writers we find references to several Anahuacs; as, for instance, Anahuac-Ayotlan and Anahuac-Xicalanco, the latter applied to the district around the lake or lagoon of Xicalanco in Tabasco. From the circumstance of their having established themselves originally around the lakes of Chalco and Tezeuco, the traditional tribes of Mexico have been called Anahuatlacas, people living by the water. It is alleged that these tribes came from some northern region, supposed by some to have been from Asia by way of Behring strait, and that the ruins of ancient edifices, known as *casas grandes*, in New Mexico and Chihuahua,

mark the path of their migration. It is, however, known to critical students that their original seats, figuratively represented as seven caves, were somewhere in the vicinity, probably on some of the islands, of Lake Michoacan; and that when they reached the region of Anahuac, they were simple barbarians, clothed in skins and living by the chase. Around the lakes of Mexico, however, they found the feeble remnants of a people far advanced in civilization, agriculturists and architects—the Tullhuatecas, a name corrupted by uncritical writers into Toltecs. These Tullhuatecas were unable to resist the irruption of the seven warlike tribes, but gradually taught them agriculture and the arts, and thus laid the foundation of the Tezeucan and Mexican empires, in which civilization and barbarism, lofty religious precepts and the most cruel rites, were incongruously mingled. The Anahuatlacas were precisely the people better known as Aztecs (see AZTECS); and the name of Anahuac is now only understood as applying to the plateau of the city of Mexico.—This great table land comprises three fifths of the territory belonging to the Mexican republic, and has an elevation of 4,000 to 8,000 feet above the level of the sea. E. and W. it is bounded by the two great chains of mountains into which the Cordillera of Central America is subdivided in its northward progress. Out of this plateau rise many lofty mountains, including the stupendous volcanoes of Jorullo and Popocatepetl, but it is generally level.

ANATIS, or *Anahid*, an oriental goddess, anciently worshipped by the Lydians, Armenians, Cappadocians, and Assyrians. The classical writers identify her sometimes with Diana, sometimes with Venus, and she appears to have combined the attributes of both these goddesses. Her temple was magnificent, her statue golden, her worship most lascivious.

ANALYTICAL GEOMETRY, a branch of mathematical science which consists in the application of algebra to geometry. It may be divided into three parts, according to the branch of geometry to which the algebra is applied. 1. Applying algebra to elementary geometry, it furnishes means for the easy solution of the most intricate problems, the simplification of demonstrations, the finding of constructions, the discovery of new propositions, &c. 2. The application of algebra to the conic sections and other curves has simplified this study and greatly expanded the knowledge of the higher geometry, which treats of other curves than the circle. 3. Its application to the system of coördinates in space, invented by Descartes, gave birth to a new view of the geometry of space, simplifying and expanding largely that branch called stereometry. 1st. In the solution of geometrical problems by algebra the figures are drawn as if the problem was solved, and if necessary, such additional lines as may establish known relations between the different quantities; then the known and unknown quantities

are expressed by letters of the alphabet, and the relation between them are, if possible, expressed in algebraic formulas or equations; these, rightly treated after the rules of algebra, give in the end an expression in known quantities equivalent to the unknown quantities. The results indicate the solution, either a manner of construction or a new geometrical relation, or it reveals an unknown property or theorem. 2d. In order to apply algebra to curved lines in general, use is made of the method of coördinates invented by Descartes. It consists simply in accepting two lines drawn through one point, by preference perpendicular one to the other, and defining the position of any point by its distance from either line or coördinate; these distances are respectively called the abscissa and ordinate, and customarily expressed by the signs x and y . Selecting now such a point successively at various places of an arbitrary line, there will be a certain relation between these distances, that is, between x and y , which may be expressed by an equation; the simplest equation is $y = ax$, or $y = ax + c$, which is an equation of the first degree, and the equation of the straight line. If the line is a parabola, the equation will be of the second degree, and in its simplest form is $y = ax^2$, or $y = ax^2 + c$. All the other conic sections can be expressed by equations of the second degree. Every curved line has in this way its corresponding equation of the third, fourth, or some other higher degree; for instance, the so-called cisoid corresponds to the equation $y^2 = (a + x)^3 \div (a - x)$. 3d. But the grandest application of this ingenious method of expressing positions of points was the next step made by Descartes of constructing coördinate planes, being three planes intersecting at one point, by preference at right angles, forming thus a trihedral angle. (See ANGLE.) The position of any point in space is thus determined by its distance from each of these three planes or faces of the angle. In such case there are of course three distances to be considered, x , y , and z , requiring two equations to determine the nature of a line. For instance, $y = ax + c$ and $x = cz + d$ is the equation for a straight line in space, while $y = ax^2 + c$ and $x = cz^2 + d$ represents the equation of a parabolic curve of double curvature, that is, one which cannot be laid on a plane surface, but a parabola drawn on a parabolic surface. Of course the number of different curved lines is as infinite as the number of different possible equations. This part of analytical geometry has given rise to the foundation of a much simpler but very useful and practical branch, by the great French mathematician Monge, namely, descriptive geometry.

ANAM, or **Annam**, sometimes called from one of its provinces **Cochin China**, an empire occupying the eastern portion of the Indo-Chinese peninsula, between lat. $8^{\circ} 30'$ and $23^{\circ} 30'$ N., and lon. 100° and 109° E., and bounded N. by China, E. and S. by the China sea, W. by Siam,

and N. W. by Burmah; area about 200,000 sq. m.; pop. probably about 15,000,000. Before the French conquests (1859-'62) the empire included three distinct provinces and part of a fourth, Cambodia. Tong-King or Tonquin, the largest province, occupies the northern part and borders on China; Cochin China proper, or Dang-Trong, extends southward in a narrow strip along the eastern coast; Tsiampa forms a continuation of this strip still further south; while that portion of Cambodia formerly belonging to Anam extends to the delta of the

Cambodia river. Besides these provinces, a portion of the territory occupying the mountainous centre of the Indo-Chinese peninsula, and inhabited by the Laos and Mui tribes—primitive peoples living under patriarchal chiefs of their own—is also under the dominion of Anam; but as these tribes are also tributary to Siam and other countries, and as they profess allegiance now to one, now to another, the extent of the Anamese dominion is indefinite. A considerable range of mountains extends

through the whole length of the empire, parallel with the eastern coast, and about 30 m. distant from it. From these flow numerous rivers, which, though generally too shallow for easy navigation, thoroughly irrigate the country. The great river Mekong or Cambodia, emptying into the China sea and gulf of Siam by many mouths, richly fertilizes that part of Cambodia formerly subject to Anam, but now under French rule as a part of French Cochin China. Throughout the southern part of Anam, but especially near this delta, the country produces great abundance of rice, sugar, spices, and tropical fruits. The mountains supply excellent timber for ship-building, besides ebony and other valuable woods. The inhabitants of the northeastern coast live in great part from the product of the fisheries.—The Anamese are a people somewhat akin to the Chinese in language and in many of their most important customs; but they also partake largely of the Malay characteristics, and evidently form a link between the Mongolian and Malay races. They are generally quiet and inoffensive, indolent and fond of gayety. They wear their hair long and gathered in a knot on the top of the head, have little beard, and dress in simple frocks and wide trousers of cotton or silk. Many Chinese merchants live among them, and carry on commerce, which the natives neglect, in rice, indigo, and silk. The last the Anamese manufacture with considerable skill, but they have few other industries. Their religion is professedly Buddhism, and the higher classes even adopt Confucianism; but they are not a religious people. The social customs of the Anamese are very similar to those of the Chinese; but though the women are much oppressed, they are not obliged to live in seclusion. Weddings and funerals are celebrated with great ceremony. The mountain tribes already noticed claim to be the aborigines, and have their own religions and customs. (See LAOS.)—Anam is governed by an emperor with absolute power; and under him are the mandarins, or officials, forming a nobility sharply distinguished from the body of the people. Embassies are annually sent to Peking, but Anam no longer pays tribute to the Chinese empire. Mandarins appointed by the emperor govern the provinces, and control the standing army, which is comparatively large. The capital of the country is Hué, at the mouth of the river of the same name.—The early history of Anam is involved in obscurity. It is only known that frequent wars with neighboring powers determined its boundaries, and that the empire was formerly entirely subject to China. In the latter half of the 13th century Marco Polo visited the country. The Portuguese were the first Europeans who actually resided there. In the 17th century, when Anam was in its greatest prosperity, the Jesuits introduced Christianity, and propagated it with such energy that by the close of the 18th century French priests had converted the emperor, Gya-Long,

and established a hierarchy of great influence. The succeeding emperors, however, rejected its doctrines and persecuted priests and converts. The present emperor, Tu-Duc, has especially opposed Christianity; and the murder of several missionaries between 1854 and 1858 seemed to the French government a sufficient cause for revenge, while it served as a pretext for the acquirement of a French colony in the East. In 1858 a French fleet, assisted by several Spanish vessels, captured Turon, a town near the capital, Hué. In 1859 the French took Saigon, an important town on the river Saigon. After an obstinate resistance on the part of the Anamese, who succeeded in prolonging the war for four years, the French, who had taken many towns and the whole province of Saigon, dictated terms of peace by which they became possessors of that province as well as of Bienhoa and Mytho; these remain in their possession and form, under the name of Cochin China, the only important French colony in the East. (See COCHIN CHINA.) By the treaty, three ports in Tonquin were opened, and Christianity was permitted throughout Anam. An insurrection took place in December, 1862, but it was quelled by the French.

ANAMBOE, a seaport town on the Gold Coast of Africa, 10 m. E. of Cape Coast Castle; pop. about 5,000. It is the seat of considerable trade, and formerly had a large traffic in slaves. The British fort here is the strongest on the coast. The exports are gold dust, ivory, palm oil, and peanuts; and the imports are silks, tobacco, wines, guns, and cutlery.

ANANIAS, the name of three persons mentioned in the Acts of the Apostles. **I.** A disciple at Jerusalem, who, having sold his property for the common cause, conspired with his wife Sapphira to give in a part of the price and reserve the rest, representing that he gave all. Peter is related to have discovered the impious fraud at once, and the Holy Ghost to have avenged it by striking both the deceivers dead. **II.** A devout man who dwelt at Damascus, and who is recorded to have been warned in a vision to go and find Paul, and restore him to sight, after he had been struck blind at his conversion. According to tradition, he was afterward bishop of Damascus and a martyr. **III.** A high priest before whom Paul was brought for trial at Jerusalem, and who commanded Paul to be smitten on the mouth (Acts xxii.). Paul being sent from this tribunal to Felix, Ananias among others went up to accuse him of being “a pestilent fellow and a mover of seditions,” &c. He was, according to Josephus, nominated to his office by Herod, king of Chalcis, A. D. 48, sent to Rome in 52 to answer before Claudius a charge of oppression brought forward by the Samaritans, at a later period deposed, and finally assassinated at the beginning of the Jewish war.

ANASTASIA, the name of several saints of the Roman and Greek churches. **I.** Anastasia the Elder was a martyr of the time of Nero, a pupil

of St. Peter and St. Paul. Her festival day is April 15. **II. Anastasia the Younger**, of an eminent Roman family, was brought up in the Christian faith by her mother Flavia, persecuted by her heathen husband Publus, and finally burned in Aquileia, in 303. Her day is Dec. 25. **III. Anastasia**, the daughter of an eminent Greek family of Constantinople, attracted by her beauty the attention of the emperor Justinian. She resisted his dishonorable proposals and retired to Alexandria, where she lived for 28 years as a monk, her sex remaining unknown till her death in 567. Her day is March 10.

ANASTASIUS, the name of four popes. **I. Saint**, occupied the Roman see 398-402. He was contemporary with Jerome, Chrysostom, and Augustine, and is remarkable for having condemned various axioms and writings of Origen. Several letters by him are extant. **II. Saint**, pope from 496 to 498. A letter from him to Clovis on his conversion and some fragments on the eastern schism are preserved. **III.** From 911 to 913. His rule was gentle, but no details of his life are known. **IV.** From July 9, 1153, to Dec. 2, 1154. He had previously been greatly distinguished as governor of Rome, and as pope favored the knights of St. John of Jerusalem.

ANASTASIUS, the name of two emperors of Constantinople. **I.** Surnamed Dicorus, born about 430, died in 518. He was a member of the lifeguard (*silentiarii*) of the emperor Zeno, on whose death in 491 he was proclaimed emperor through an intrigue with the empress Ariadne, whom he soon afterward married. Though more than 60 years of age, he began his stormy reign by suppressing with great ability a rebellion organized against him by Longinus, Zeno's brother, who had aspired to the throne, and by two other natives of the Isaurian province, whose names were also Longinus. Rebellions, plagues, earthquakes, and a severe famine filled the next years of his reign with hardship for the people and difficulty for the emperor; and finally the Persians under their king Cabades invaded the empire with such success, that Anastasius was compelled to purchase peace by an enormous tribute (505). In the opening years of the 6th century Anastasius became involved in the religious disputes of the time, and was anathematized by Pope Symmachus for favoring the Eutyhelian heresy. **II.** Originally named Artemius, chosen emperor in 713 as successor to Philippius, whose minister he had been. He began his reign by punishing Rufus, the traitor who had deposed Philippius. In 715 he undertook an expedition against the Arabs, but it was rendered futile by the mutiny of many of the sailors of his fleet. The mutineers proclaimed as emperor one Theodosius, a government official, who besieged Constantinople and Nicaea, in which latter place Anastasius was when attacked. The latter was driven from the throne (716), and retired to a monastery, while the rebel became emperor as Theo-

dosius III. In the reign of Leo III, Anastasius endeavored to regain the throne, but was defeated and put to death (721).

ANASTOMOSIS (Gr. *ἀνά*, through, and *στόμα*, mouth), the communication or insolation of different blood vessels by opening one into the other. In the arteries it is comparatively rare, as these vessels divide and separate from each other, for the purpose of distributing the blood to different organs. Nevertheless, it always exists in certain situations, where the principal trunk is liable to compression, and where this compression would have the effect of shutting off all nourishment from the parts beyond were there no other means of vascular communication. Thus the arterial branches situated above and below the principal joints anastomose with each other; and if the main artery of the limb is compressed or tied, the blood still finds its way to the parts below by this circuitous route of communication. The arteries supplying the intestines also communicate freely with each other, so that the circulation is not interrupted by the folding or bending of the parts upon each other. The most remarkable instance of arterial anastomosis is that at the base of the brain, where the two principal arteries entering the skull from behind, namely, the right and left vertebral, unite in a single trunk, which afterward divides and sends branches forward on each side to insolate with the two internal carotid arteries, which themselves afterward communicate with each other by a transverse anastomosis at the anterior part of the brain. Thus there is at the base a continuous vascular circle or ring, called the "circle of Willis," supplied with blood at the same time from four different arteries, the two carotids and the two vertebrales, and from which branches are sent off to the various parts of the cerebral substance. In the veins anastomosis is much more frequent, even the larger veins of the upper and lower limbs seldom continuing far in their course without giving and receiving branches of communication with adjacent veins. Thus a passage for the blood from the extremities toward the heart is constantly kept open, notwithstanding the compression to which these vessels are liable by the contraction of the muscles and accidental pressure. In the capillary blood vessels, finally, anastomosis is abundant and constant. All the capillary blood vessels, in fact, insolate with each other in every direction, and in such profusion as to form a network or plexus of minute vessels, with corresponding interspaces or islets included between the meshes. This provides for a continuous and uniform supply of blood to every part of the organ, and brings the blood into close contact with the substance of its tissue.

ANATA. See **ΑΝΑΘΟΤΗ**.

ANATHEMA (Gr. *ἀνάθημα*, from *ἀνατίθημι*, I set apart), in the Greek classics, anything set apart as an offering to the gods, applied to the numerous votive gifts which were suspended upon the walls of temples or exposed upon

public altars. By change of usage it afterward became the name of anything devoted to the infernal gods, anything execrated and execrable, causing the abhorrence of men. In this sense it was adopted by the Christian church as the synonyme of the Hebrew *'herem*, which signifies both a thing devoted to God and extermination, and which was used by the Jews in pronouncing the ban of excommunication. The Old Testament gives many examples of *'herem* or anathema. Moses pronounced the anathema against those Canaanitish cities which should refuse to submit to the Lord, and Joshua declared everything captured in Jericho *'herem*, and punished Achan for violating the ban. In the New Testament it is used in the sense of "set aside" or "accursed." In the Roman Catholic church it is a sentence pronounced against heretics and schismatics, or against those who wilfully and obstinately persevere in a course of conduct which the church condemns. It implies exclusion from the communion and society of the faithful, who are taught to regard the object of this ecclesiastical penalty as one who by his crimes has cut himself off from the church and merited the flames of hell. The anathema, however, is not supposed to be a sentence of eternal reprobation; it is a temporal punishment, similar in its effects to excommunication. Most of the dogmatical decrees of the church close with anathemas against all who presume to deny them. Thus the council of Trent employs it against such as deny the existence of purgatory, the doctrine of the real presence, &c.

ANATHOTH, a town of ancient Palestine, the birthplace of Jeremiah, about 4 m. N. of Jerusalem. It was in the possession of the tribe of Benjamin, and a city of priests. It was once a considerable place, but is, according to Robinson, identical with the present Anata, an insignificant village. Anata is in the top of the high range of hills north of Jerusalem, and commands a prospect of the Dead sea. It was in Anathoth that Jeremiah bought the field (witnessed by Baruch), as a symbol of the return from the captivity.

ANATOLIA. See *ASIA MINOR*.

ANATOMICAL PREPARATIONS, the skeleton and other portions of the dead body preserved from decomposition by various artificial methods, for the use of medical schools or science. The soft parts are usually separated from the skeleton by long-continued maceration in cold water, or by steaming or boiling; the bones are bleached, and the articulations held together by means of wires. This is called an artificial skeleton, and, when properly prepared, may be kept for an indefinite time. To preserve the natural articulations of the bones, the soft parts must be removed carefully by dissection, and many delicate sections and mechanical adaptations are required to display the internal structure, forms, and relative proportions of the skeleton and its component parts. The whole body of an animal, or any

soft portion of the body, such as the heart or the intestines, may be preserved for a considerable time in alcohol or in spirits of turpentine; and such preparations are very useful in the study of comparative anatomy. Another method of anatomical preparation consists of injecting the vessels with some colored substance to distend them, and display their ramifications in the organs, that the shape and course and relative dimensions of the vessels may be seen with ease. By means of a large syringe inserted into the main trunks of the arteries, these vessels are filled with a soft colored mass, which penetrates into the smallest branches, distends them, and makes them visible. The infused substance usually consists of a mixture of soap, pitch, oil, and turpentine, to which is added a coloring substance: red for the arteries, blue for the veins, and white for the absorbents or lymphatics. For the latter vessels quicksilver is preferred, on account of its extreme divisibility.—Dried preparations of the soft parts, such as muscles, nerves, and membranes, are preserved by covering them with a protecting coat of transparent varnish. The quicker they are dried, the better for this mode of preparation and conservation. Spirits of wine, distilled with pepper or a very strong pimento, and mixed with muriatic acid, is used for preserving them. Washing with pyroligneous acid gives firmness and whiteness to these anatomical preparations. Those which are preserved in liquids are usually kept in bottles of transparent glass, with accurately ground stoppers, to prevent evaporation, and secure them against the destructive influence of air, moisture, heat, dust, and insects.—Preparations of this kind are very necessary to preserve important specimens of normal and abnormal development in the animal economy, but they are difficult to preserve long in a comparative state of perfection. Other means have therefore been devised as substitutes for common use. Instead of anatomical preparations properly so called, anatomical imitations are now used for purposes of general instruction, and great perfection has of late years been attained in the manufacture of these works of art. Imitations of organic form and structure were formerly made in wood, as those of the abbé Fontana in the museum at Florence; or in wax, as those made by Laumonier and others in France and Italy; card-board, as by Dr. Ameline of Caen; or in lithographic drawings, woodcuts, colored prints, &c. Drawings, however perfect, are not sufficient for all purposes; and though the anatomical imitations of organs were sometimes made with rare perfection and beauty in wax, they were too expensive for common use, and could neither be taken to pieces for detailed inspection, nor handled freely without risk of injury. In 1825 Dr. Auzoux of France conceived the idea of making imitations of all the organs of the human body; not only of their general external form

and appearance, but also of their internal and minute details. For this purpose he composed a pasty mixture of a sort of papier maché which may be moulded to any form while liquid, and hardened in the form thus given. Models of the organs were made in all their different layers and proportions, with the vessels and the nerves in each, as they are found in nature; the liquid substance was then poured upon the models and allowed to harden. A complete manikin of the human body and all the internal organs was thus formed, which could be taken to pieces and put together again at will and with the greatest ease; each part being colored in imitation of nature, and labelled with a number or the real name, by which it could be recognized at any time, either in or out of its natural position in the manikin. In 1830 this art, called elastic anatomy (Gr. *κλαστός*, broken), was brought to great perfection; and a comparatively faultless model of the human body, 5 feet 6 inches in height, could be manufactured and sold for \$600. This was still, however, too expensive for many persons, and complete manikins of a smaller size (3 feet 6 inches, in lieu of 5 feet 6 inches) were manufactured, and sold for \$200 each. Each manikin contains 129 distinct pieces, forming different layers and organs or parts of organs.

ANATOMY (Gr. *ἀνατομή*, dissection), the science which treats of the structure of organized bodies as learned from dissection. During the primitive ages of the world anatomy was little cultivated as a science, and hence the art of surgery was undeveloped. In later ages religious scruples forbade the opening of the human body to inspect the viscera; and students of anatomy were limited to the dissection of animals, to gain a knowledge of internal organs and their functions. The first branch of this science which was studied from nature was therefore animal anatomy, now called "comparative anatomy," from the fact of different types of the animal kingdom differing in their internal structure as much as in their external form. Aristotle was the first to give accurate descriptions of the internal organs of different species of animals, and for many centuries after him little was done to advance the science by actual dissection and observation. Hippocrates had some accurate views of osteology, but his descriptions of the brain and the heart, and their respective functions, show that he knew little of anatomy. The first important development of human anatomy, of which we have any authentic record, took place at Alexandria in Egypt during the reign of the Ptolemies. Erasistratus of Ceos and Herophilus of Chalcedon are mentioned by Galen as eminent anatomists of the Alexandrian school; and Herophilus is said to have obtained permission to open and inspect the bodies of living criminals, to gain a knowledge of internal organs and their modes of action. The writings of Celsus show that he cultivated anatomy, but the next

great steps in advance were made by Claudius Galenus, the celebrated physician of Pergamus. Galen was born at Pergamus, A. D. 130. He collected the works of his predecessors and pursued the study of anatomy, as far as he was able, by dissecting animals. He first showed that arteries in the living animal contain blood, and not air alone, as had been supposed by Erasistratus; but it did not occur to him to notice the circulatory movement of the blood in the vessels. This was reserved for Harvey, many centuries later; before which time the blood was supposed to move, in the veins as well as in the arteries, from within outward. During the middle ages the natural sciences, neglected by the Christians, were mainly cultivated by the Arabs; but, as the Mohammedan religion forbade the dissection of human bodies, their physicians were obliged to rely on the knowledge transmitted to them by the school of Alexandria, and chiefly on the works of Galen. Their writings add little or nothing to the science of anatomy, unless it be the names of certain organs translated from the Greek into the Arabic, and afterward to some extent adopted by Italian and Spanish writers on anatomy. The spirit of religious liberty and commercial enterprise revived the cultivation of the arts and sciences in Italy during the 14th century; and Mondino da Luzzi, professor of anatomy at the university of Bologna, first publicly dissected two human bodies in the presence of medical students in 1306 and 1315, and shortly afterward published a description of the organs from direct observation and dissection. This, with the works of Galen, served as a text book for the schools till the 16th century, when the study of human anatomy from actual dissection became general in the medical schools of Italy. From this time forward human anatomy has been constantly studied from actual dissection and observation, in those countries of Europe where religious considerations offered least resistance to this mode of proceeding. First Italy, then Holland, Denmark, Sweden, Germany, France, England, and America, have furnished names of eminence in the cultivation and advancement of the science of anatomy; but popular prejudices have hindered the free dissection of human bodies in medical schools, until a very recent date, in many states of Europe, and also in this country. Anatomy is now one of the most important branches of natural science, and its various departments have become so extensive as to require separate divisions and distinct methods of analysis. We have thus comparative anatomy, including every type of animal organization, not excepting man, as one of the types of the animal kingdom; and human anatomy as a distinct branch of study, in connection with physiology, pathology, surgery, and therapeutics. These again are subdivided into distinct branches, under the names of regional or surgical anatomy, descriptive or special anatomy, histological or general anatomy, and microscopical or

minute anatomy.—Surgical anatomy treats of the relations of organs to each other, in each region of the body, such as the positions, forms, dimensions, structure, and peculiarities of nerves and vessels, muscles, glands, and membranes, in the head, the trunk, and the limbs, a proper knowledge of which is necessary to guide the surgeon in his delicate and difficult operations. He must know where to cut and what to avoid in operating on the living body; for the life of the patient might be jeopardized if the surgeon were not well acquainted with the relative anatomy of vital organs. Descriptive anatomy treats of the distinct systems which pervade the whole frame, or perform a certain class of functions in the organism; such as the bones of the skeleton, the muscles, the skin, and the nerves of the whole body; the digestive system; the blood vessels; the respiratory organs; the generative and the urinary apparatus; the blood and the secretions. General anatomy treats of the different tissues which compose the special organs or classes of organs in different parts of the body; such as the three distinct coats of the stomach, *i. e.*, the mucous membrane, the muscular coat, and the serous membrane or peritoneal covering; the areolar or connective tissue, found between the mucous and muscular layers, and disseminated more or less extensively throughout the body. Minute anatomy investigates the elementary basis of organic nature, and by the aid of chemistry and the microscope observes and analyzes the atomic and cell structure of the tissues which compose the organs of the body; the fluids and contents are also subjected to this minute analysis. Animal anatomy was scantily and almost exclusively studied by the ancients; human anatomy was fairly commenced by the Italian schools of the 14th, 15th, and 16th centuries; the descriptive branch was chiefly cultivated throughout Europe until the end of the 18th, when Bichat instituted and almost originated the systematic study of general anatomy. Microscopic observations had been made by Malpighi and other anatomists, but many of the great discoveries of comparative and general anatomy have been made in the present age; and the systematic study and development of minute anatomy date from the improved construction of the compound microscope in 1832, before which time it was impossible to make much progress in this most important branch of science. Descriptive or special anatomy is limited to the study of the parts which form the body of one type or individual, or of the two sexes of one species, as man and woman. It does not, however, exclude reference to age and difference of race.—The organs of the body have been classed in various ways by different anatomists, and mostly according to the nature of their special structure and peculiarity of use or function. Bichat's method, slightly modified, is most in use, and is perhaps the best. By this the organs are classed as follows: I. Organs pertain-

ing to the animal, voluntary, or relational functions. II. Organs pertaining to the nutritive functions. III. Organs pertaining to generation, or the reproductive functions. To the first class belong the organs of locomotion, innervation, voice, and sensation. 1st. The skeleton, composed of bones, cartilages, ligaments, and joints, as instruments of locomotion and forming the subject of what is termed osteology. 2d. The muscular system, composed of muscles, tendons, sheaths, and their appendages, as agents of locomotion, forming the subject of myology. 3d. The nervous system, composed of medullary white substance and gray vesicular matter, enclosed in sheaths of serous and fibrous membrane, forming the brain, spinal cord, ganglia, and nerves. The special study of the structure and functions of the nervous system and appendages is termed neurology. 4th. The vocal organs, as an apparatus of relational use between man and the external world, are the larynx or throat, and the mouth; the one as an organ of the voice, and the other as an organ of articulation or speech. 5th. The special organs of sense are distinguished into proper and common; taste, smell, sight, and hearing belong to the former, and touch, the sense of temperature, and the muscular sense of resistance, weight, lassitude, &c., belong to the latter. The mouth, the nose, the eyes, and the ears are special organs, but the whole external surface of the body serves for the sense of touch and temperature, while the whole internal muscular structure seems to be affected by the sense of lassitude, and the muscular parts of the trunk and limbs are affected by the sense of resistance to external weight or force.—To the second class of organs, pertaining to the functions of nutrition, belong the organs of digestion, respiration, circulation, secretion, and excretion. 1st. The digestive system consists of the alimentary canal, together with its accessory organs, such as the salivary glands, the liver, and the pancreas. The alimentary canal, consisting of its successive portions, namely, the mouth, œsophagus, stomach, small intestine, and large intestine, receives the food and accomplishes its digestion by the mechanical operation of the teeth in mastication, followed by the modifying action of the various digestive secretions. 2d. The heart is the centre of the circulatory system, which consists of two distinct circuits, called pulmonary and systemic. From the right ventricle of the heart the dark impure blood is sent through the pulmonary arteries into the lungs, where the minute capillary blood vessels are exposed to the almost direct contact of the air, from which oxygen is absorbed to vivify the blood, giving it a bright scarlet red. A thin membrane intervenes between the air in the lungs and the blood, but this does not impede the absorption of oxygen and the exhalation of carbonic acid gas, the one to give new life and the other to rid the blood of poisonous gas and effete matter. When thus

purified and renovated in the lungs, the blood returns to the left side of the heart, performing a complete circuit in the region of the heart and lungs alone, for this sole purpose. It is then propelled from the left ventricle of the heart, through the aorta and all the arteries of the whole body, into every organ, for the purpose of nutrition. The capillary vessels ramify minutely in every organ, and the tissues of the part absorb the nutrient portions of the fluid, and return waste matter to the veins, in exchange for the nutriment brought to them by the arteries. The general system of arteries carries pure blood to all parts of the body, and the general system of veins returns impure blood from all parts of the body back into the heart, to be thence sent into the lungs for purification, and thus keep up perpetual circulation and renovation. 3d. The respiratory organs are the larynx, the trachea or windpipe, the bronchial tubes, and air vesicles within the lungs. Their function is to breathe in new supplies of air to vivify the blood, and to exhale carbonic acid and other vitiated matters, which are poisonous when accumulated in too large a quantity. 4th. The kidneys separate from the blood the elements of the urine, and thus rid the system of another kind of waste matter, which also becomes poisonous if allowed to accumulate within the vessels that contain and circulate the vital fluid. When in the bladder the urine is not dangerous, because no longer mingled with the blood, unless too much accumulated and too long retained.—To the third class of organs belong the reproductive systems, male and female. These are not essential to the life of the individual, as they may be extirpated without danger even to the health.—General anatomy treats of the different sorts of tissue composing the organs of the body. Bichat made 21 distinctions of animal texture, but later anatomists have modified his method of distinction. It will suffice here to say that the sheath or covering membranes of bones, muscles, nerves, and many other organs, are formed of a fibrous kind of membrane, much alike in texture and in its leading properties, whether it be the periosteum of the bones, the fibrous sheath of the muscles, the neurilemma of the nerves, or the *tunica albuginea* or covering of the testicles, the ovaries, &c. Serous membrane is also the same kind of tissue in every part of the body, although called arachnoid when it serves as a covering for the brain, pleura as a covering for the lungs, and peritoneum as a covering for the viscera of the abdomen, and a lining for the inner walls of the trunk below the chest. The leading elements of structure in the organs of the body are fibrous tissue, serous membrane, bony texture, cartilaginous texture, fibro-cartilage, muscular fibre of various kinds, striated and non-striated, glandular tissue, mucous membrane, dermoid tissue or skin, cuticle or epidermic tissue on the surface of skin and mucous membrane, horny tissue, as the hair

and nails, white nervous or medullary substance, and gray nervous or ganglionic or vesicular matter; and diseases are characterized in many instances, not so much by the particular organ affected in any part of the body, as by the particular tissue affected by disease in any given region.—Minute anatomy goes deeper still into details, and with the microscope and chemical analysis endeavors to find out the elementary constitution of the tissues and fluids of the body. Thus chemistry reveals to us that the simple elements found in the tissues are oxygen, carbon, hydrogen, nitrogen, sulphur, phosphorus, magnesium, calcium, sodium, potassium, chlorine, fluorine, silicon, iron, and manganese, with perhaps a trace of two or three others. The compound elements are of three classes: first, substances of an organic nature introduced with the food, or formed in the processes of digestion and nutrition; secondly, substances resulting from the waste or disintegration of the body; and thirdly, substances of inorganic or mineral origin. The inorganic compound substances are water, chloride of sodium, chloride of potassium, fluoride of calcium, hydrochlorate of ammonia, carbonate of lime, bicarbonate of lime, carbonate of magnesia, bicarbonate of potassa, bicarbonate of potassa, carbonate of soda, bicarbonate of soda, sulphate of potassa, sulphate of soda, sulphate of lime, basic phosphate of lime or bone earth, acid phosphate of lime, phosphate of magnesia, phosphate of potassa, neutral phosphate of soda, acid phosphate of soda, ammonia, and phosphate of magnesia and ammonia. The compound substances resulting from waste of the human body are principally carbonic acid, urea, creatine, creatinine, urate of soda, and urate of potassa. The substances of an organic nature related to the nutrition of the body are the uncrystallizable albuminoid matters, such as albumen, albuminose, fibrine, pancreatine, mucosine, musciline, globuline, hematine, biliverdine, and melanine; crystallizable substances, either containing nitrogen, such as glycocholate and taurocholate of soda, or destitute of nitrogen, such as sugar and fat. By microscopic observation, the elementary structure of the tissues is found to consist mostly of minute cells, fibres, tubes, and a homogeneous or granular substratum. Schwann believed that all the tissues of the body were formed from cells; but subsequent observation shows that although many tissues retain their original cellular structure throughout life, and many more are formed from cells which are afterward metamorphosed, there are some in which no other cell agency is employed than that which occurs in the elaboration of the plastic material; a certain structureless lamella, commonly called basement membrane, offers no visible traces of cell structure, but rather resembles the filmy tissue of which the walls of minute cells themselves are formed. It is, however, generally believed that minute cells, or other analogous or derived forms, constitute

the elementary organic parts of nearly every tissue, and that all chemical changes occur in them, as integral elements of structure, without altering their numbers and relative positions; that these minute anatomical elements, in fact, are as permanent in form as the tissues and the organs they compose; and that all growth in the individual organism takes place by a relative enlargement of their size, and not by any increase of their number; so that, as the organs remain the same in form and number in the adult as in the new-born child, the same is true of the tissues that compose the organs, and the microscopic cells composing tissues. The principal varieties of cells now recognized are: the red globules of the blood, flattened, circular bodies, homogeneous in structure, from $\frac{1}{40000}$ to $\frac{1}{30000}$ of an inch in diameter; the white globules of the blood, which are colorless and granular, spherical in form, and $\frac{1}{25000}$ of an inch in diameter; scale-like epithelial and epidermic cells, very thin, pentagonal or hexagonal in shape, with a round or oval nucleus imbedded in their substance; columnar and ciliated epithelium cells, lining certain parts of the alimentary canal, air passages, generative organs, and ventricles of the brain; glandular epithelium cells, forming the active agents of secretion in the glandular organs; and the nerve cells of the brain, spinal cord, and ganglia. The fibres are: the white fibres of areolar tissue, of tendons, fasciæ, and the like; the yellow elastic fibres of elastic tissue; the compound muscular fibres; and ultimate nervous filaments. The tubular elements are the capillary blood vessels and lymphatics, and the straight or convoluted tubules of the kidneys, the testicles, and some of the glandular organs. The homogeneous or granular substratum, in which these anatomical elements are imbedded, varies in consistency and composition in the different tissues.

ANATOMY, Comparative. See **COMPARATIVE ANATOMY.**

ANAXAGORAS, a Grecian philosopher, born at Clazomenæ in Ionia, about 500 B. C., died in 428. He rejected wealth and honors that he might indulge his love of meditation and philosophy. From Clazomenæ he removed to Athens, where he lived in the closest intimacy with Pericles, and also numbered among his friends or pupils several of the most distinguished Athenians of that period. Anaxagoras is generally considered the first of the Greeks who conceived of God as a Divine Mind (by him termed *νοῦς*) acting upon matter with conscious intelligence and design. He taught that the sun was no deity, but an inanimate fiery mass, and therefore not a proper object of worship; and that the miraculous appearances at sacrifices were explicable by natural laws. He suggested that the moon shone by reflected light, and rightly explained solar and lunar eclipses. His attempt to account for these phenomena, at that time regarded as supernatural, on natural principles, brought him into

great danger. He gave moral expositions of the myths of Homer, and explained the names of the gods by allegory. As a penalty for what was accounted his impiety, he was condemned to die; but through the influence of Pericles his sentence was commuted to banishment. He retired to Lampsacus, on the Hellespont, and died there a few years later in poverty. A little before his death the senate of Lampsacus sent messengers to inquire what commemoration would be most acceptable to him; he answered, "Let all the boys have a play day on the anniversary of my death!" This festival was called Anaxagoreia, and was observed for centuries. The fragments of his works have been collected by Schaubach (Leipzig, 1827), and by Sehorn (Bonn, 1829).

ANAXARCHUS, a Grecian philosopher, a native of Abdera in Thrace, who attended Alexander the Great into Asia, and succeeded in winning his friendship by his wit and servility. After the death of Alexander, in 323 B. C., Anaxarchus, while returning to Greece, is said to have been shipwrecked on the coast of Cyprus, and pounded to death in a mortar by order of Nicocreon, one of the princes of that island, whom he had offended.

ANAXIMANDER, a Grecian philosopher of the Ionian school, born at Miletus in 610, died about 547 B. C. He is said to have led a colony to Apollonia in Illyria, and many wonderful deeds and inventions are ascribed to him. Grecian philosophy is indebted to him for the word *ἀρχή*, signifying origin or principle. His general doctrine, as stated by ancient writers, concerning the origin of nature, was that the first principle of all things is infinity (*τὸ ἀπειρον*); that the universe, though variable in its parts, as a whole is fixed and unchangeable; that infinity is the beginning and end of all things. He was the first to commit philosophical doctrines to writing. He wrote a treatise on geometry, and made calculations on the distances and size of the heavenly bodies. He held that the stars are globes of air and fire animated by divinity, that the earth is a globe fixed in the centre of the universe, and that the sun is 28 times as large as the earth. He was the first to compose a treatise on geography, and also prepared a chart of such portions of land and sea as he was acquainted with. According to some, he invented the sun dial.

ANAXIMENES. I. A Grecian philosopher, born at Miletus, flourished in the latter half of the 6th century B. C. He taught that the essence of all things is air, whence all things are produced by condensation and rarefaction through eternally existing motion; that the sun and moon are fiery bodies of a flat, circular form; that the stars are also fiery substances, fastened like nails in a crystalline sphere; and that the earth is a tablet resting on air. **II.** A native of Lampsacus, a historian and rhetorician, and one of the preceptors of Alexander the Great. He wrote a history of

Alexander's reign, and that of his father Philip, and also a history of Greece.

ANCACH, a N. W. department of Peru, between the Andes and the Pacific, bounded N. E. by the Marañon; area, about 18,000 sq. m.; pop. 317,000. It is one of the most fertile portions of Peru, producing heavy crops of cereals and a large quantity of sugar, and in some parts cotton. The elevated table lands are made very fertile by irrigation. Excellent marble is quarried and valuable minerals abound. The capital is Huaras, in an extensive, beautiful, and populous valley of the same name. Wood here is scarce, and its place is supplied with *champa*, a black vegetable matter resembling lignite. The other chief cities are Huaylas, Santa, Huarí, Cajatambo, Pomabamba, and Pallaseca, each the capital of a province or district of the same name. It was through the passes of this department that the Colombian army, in the war of independence, made its astonishing march into Peru to attack the Spanish forces at Junin.

ANCELOT. I. Jacques Arsène François Polycarpe, a French dramatist, born in Havre, Feb. 9, 1794, died in Paris, Sept. 7, 1854. He held an office in the ministry of the marine, which he lost after the revolution of 1830, as well as a pension granted him by Louis XVIII. In 1841 he was received a member of the French academy. His first tragedy, *Louis IX.* (1819), had great success from its adoption by the royalists as an offset against Casimir Delavigne's *Vêpres siciliennes*. After retiring from office he devoted himself chiefly to the rapid production of vaudevilles and light pieces for the minor theatres. He also published *Six mois en Russie*, in prose and verse (1826); *Marie de Brabant*, a poem in six cantos; and *L'Homme du monde*, a melodramatic romance, afterward dramatized. **H. Marguerite Louise Virginie Chardon**, a dramatist and novelist, wife of the preceding, born in Dijon, March 15, 1792. She collaborated largely in her husband's lighter works, and produced several successful comedies, the most popular of which was *Marie, ou trois époques* (1836). Her *Théâtre complet* (4 vols., 1848) comprises 20 plays. Her most popular novels have passed through many editions. She also cultivated painting, and in 1828 exhibited *Une lecture de M. Ancelet*, a picture which excited much attention from its portraits of nearly all the Parisian *littérateurs*.

ANCHISES, a legendary Trojan prince, the father of Æneas. He was related to the family of Priam, and was king of Dardanus in Troas. Venus was enamored of him, and, visiting him in the disguise of a Phrygian princess, became the mother of Æneas. According to Virgil, Anchises survived the capture of Troy, being borne from the burning city on the shoulders of his son, and died in Sicily shortly after the arrival of Æneas in that island. The people of Egesta, a town situated near the place where he is said to have been

buried, erected a sanctuary and celebrated funeral games in his honor.

ANCHOR (Gr. *ἄγκυρα*, Lat. *anchora*, Ger. *Anker*), a metal hook of suitable form and of sufficient weight and strength to enable a ship, by means of a chain or cable attachment, to lay hold of the bottom, and thus remain fixed in any desired position. The form of the anchor has undergone but slight modification since the time of Anacharsis, the Scythian philosopher, about 594 B. C. Before him anchors with one arm or tooth had been a short time in use, but he first added the second. The later Greek anchors were of iron, but originally they consisted of large wooden pipes filled with melted lead. In the heroic times of Greece, large stones were sunk into the water by ropes to hold the ship; and a little later bags of sand and baskets filled with rocks were used. Every ship was supplied with from four to eight anchors. The largest of them was termed the *sacra*, and was only used in times of great danger; hence the proverb, *sacram anchoram solvere*, to fly to the last refuge. The Chinese anchors, now as in ancient times, are only crooked pieces of heavy wood.—With the exception of Spain and certain of the South sea islands, where copper is occasionally employed, the metal used in the construction of anchors is the best of wrought iron. The form of the common wrought-iron anchor, with the manner in which it "lays hold" of the sea bottom, may be best understood by a refer-

FIG. 1.—Common Anchor.

ence to fig. 1. It is evident from the direction of the strain that any forward movement will cause the lower fluke and arm to be buried still deeper in the earth. Anchors are called solid or ordinary when the shank and arms are wrought into a body; they are called portable when they can be taken to pieces. Each part of an anchor has a distinct name. The shank or the central part of the instrument is a round or octagonal bar of iron tapering toward one end, where it becomes square; the arms are two curved pieces projecting from the heavy end of the shank at right angles with it, and in opposite directions; the stock is a transverse beam, of wood or of iron, fastened to the square end of the shank at right angles with it and with the arms, and serves to cant the anchor when the arms fall on the bottom in

a horizontal instead of a vertical position; the square is the square end of the shank, which at the extreme end, just beyond the place where the stock is fastened, is bored through for attaching the shackle by means of a pin; the shackle is a ring, by means of which the cable or chain is attached to the anchor; the crown is the extreme end of the shank, or the external part of the arms, on which the anchor falls when let go in a vertical position; the palms or flukes are parts of the arms, of a shield-like form, which are near their extremities, and constitute the holding surface of the anchor. The angle of the face of the palm with the shank is 51° . The arms extend from the shank in a curve the outside radius of which is 35. That part of each arm which sustains the palm is called the blade, and the part which projects beyond the palm, and has to open the ground, is named the point, peak, or bill. If 100 be taken as the unit of length for both the stock and shank, then 40 will represent the average length of each arm from the crown to the bill. The relative weights of these several parts may be roughly estimated as follows: The shank, $\frac{5}{10}$ of the whole; each arm, $\frac{20}{100}$; two palms, $\frac{1}{10}$; stock, $\frac{1}{5}$; shackle, $\frac{1}{15}$. When an anchor is let go from the ship, it falls vertically through the water, and, should the bottom be an even one, the crown will strike first; but a rocky bed may compel one of the arms to receive the full force of the fall, for which reason any cross section of an arm should represent an ellipse, with the line of its greatest diameter vertical to the point of probable contact, thus receiving the heaviest strain in the direction of the greatest strength. After striking the ground the anchor falls sideways, the arms lie flat, and the stock rests on one end. A length of chain proportional to the depth of water, and so calculated that the hardest pull of the vessel will not lift it entirely from the ground, is permitted to run out. The action of the current or of the wind on the vessel soon makes her exert a traction on the chain, and this lying on the ground pulls down the shackle, bringing the stock flat on the bottom, and the arms perpendicular to it; this is called canting the anchor. The longer the stock and the shorter the arms, the less force will be required to perform this operation; hence in all anchors the stock is longer than the arms. After canting, the anchor will be dragged or will hold. Quick holding depends on the sharpness of the bill and the angle of the palm with the ground. For "weighing anchor," the chain or cable is taken in by aid of a capstan, till the bow of the vessel is brought over the shackle; here an increased pull is necessary to trip it, and the anchor is raised to its place. The property of quick tripping depends on the curve of the arm, and on the angle of the palm; they have to be such that when the shackle is pulled up vertically, the bill cuts open a short curved circular way in which the palm and arm fol-

low. When the palm is out, the ground is torn open by the arm, which is comparatively sharp, and acts with a more advantageous leverage than the palm would. More than two thirds of the ruptures of anchors happen in the operation of weighing. We have said that the arms ought to be thicker in the dimension parallel to the shank, to resist shocks against rocks. The same is necessary to resist the strain in tripping. The shank is exactly in the same circumstances, and has to be thicker in the direction of the arms, and to decrease in size from the crown to the square. Though theory indicates rectangular sections as best for the arms and shank, they are in practice made round or oval, or at least the angles are much rounded. This has been found necessary for the preservation of cables, which often take a turn around the anchor when the vessel changes its direction with the tide or wind.—The forging of an anchor requires the constant superintendence of an educated engineer, while the workmen should be chosen with an eye to their skill and judgment, as well as muscular strength. A sufficient number of wrought-iron bars made from the best scrap iron, or from "Welsh mine iron," are bound together by iron hoops, forming the faggot; this is placed in a specially contrived furnace, where it is brought to a white or welding heat, when it is removed by the aid of a crane to the anvil, and subjected to the rapid and powerful blows of the stamping hammer. When an approximate form is thus obtained, the finishing is done by heavy sledges in the hands of the anchor smiths. The arms and stock may be forged separately and then welded together at the crown, or, as in the process patented by Mr. Perrins of England, the whole may be built up by the welding together in a given order of a number of separate pieces, so adjusted as to secure the greatest strength in the direction of the heaviest strain. When the stock is of wood, it consists of two beams, generally oak, mortised in the centre so that they may embrace the square, upon which they are firmly bolted; the middle thickness should be one twelfth of the length, and the whole should taper from the centre out, the diameter of the end being about one half that at the centre. The iron stock, which is rapidly replacing that of wood, is a simple round bar tipped with knobs, which prevent its entering the ground, and with one end bent at right angles. This passes through a hole in the square which is rounded out for the purpose, and is held in position by a metal ring or shoulder upon one side, and a slit and key on the other; by removing this key, the whole stock may be driven through, and thus, owing to the crook upon the end, be doubled down upon the shank, rendering it much more compact and portable.—So important is the quality of strength in an anchor, that all modifications of the tried and approved form, or any improvements that have the appearance of sacrificing strength to convenience in handling,

or even gain in holding power, seem to have been regarded with suspicion. Hence the anchor now in general use might almost have been described a century ago. In 1833 Lieut. Rodger of the English navy received letters patent for an improvement in the size and form of the palms, "having found by experience that anchors with small palms will not only hold better than with large ones, but that the arms of the anchor, even without palms, have been found to take more secure hold of the ground than anchors of the old construction of similar weight and length." He fixed upon one fifth

of the length of the arm as a suitable proportion for the length or the depth of the palm. The palm of the anchor, instead of being flat, presents two inclined planes, calculated for cutting the sand or mud instead of resisting perpendicularly. The Lenox, Mitcheson, and Aylen anchors are all improvements on the old admiralty pattern; while the Isaac anchor, an American invention, has a flat bar of iron passing from palm to palm, in addition to which two other bars unite the ends of the stock to the centre of the shank, intended to prevent the fouling of the cable. A novel and in many respects important improvement is that of the Porter anchor, having

Fig. 3.—Trotman Anchor.

movable flukes or arms; this anchor, with certain valuable alterations, is represented above as the "Trotman anchor." It will be readily seen that, by the closing of the upper arm against the shank, the chances of fouling are greatly decreased, as also the danger of the ship's grounding upon her anchor in shallow water. The accompanying table, showing the relative order in which the several anchors above mentioned stand with regard to each of the properties essential to a good anchor, was embodied in a report made by a committee of

five ship owners appointed by the lords of the admiralty to test their relative merits. The names are arranged alphabetically:

ANCHOR.	Strength computed from first crack.	Holding long and short scope.	Facility of stowing.	Quick holding.	Quick tripping.	Exemption from fouling.	Facility of sweeping.	Facility of transport in boats.	Fishing in a heavy sea way.	Cauting.
Admiralty .	4	5	1	2	1	4	1	2	2	2
Aylen	7	4	1	2	3	4	1	2	2	5
Porter, or Honiball }	2	2	3	4	2	1	4	3	5	3
Isaac	1	6	4	5	1	1	4	4	5	1
Lenox	6	3	2	1	2	3	2	1	3	2
Mitcheson .	3	1	3	1	3	2	3	2	4	4
Rodger	5	2	1	2	4	2	1	1	1	2
Trotman . . .	3	1	3	3	4	1	4	3	5	5

The estimated numerical values of these several anchors are as follows: Trotman, 1.28; Rodger, 1.26; Mitcheson, 1.20; Lenox, 1.13; Porter, 1.09; Aylen, 1.09; Admiralty, 1, standard; Isaac, 0.73. Notwithstanding the above favorable report, the Trotman anchor has not been received with general favor by ship masters, though largely used by the merchant steamers.—In general service, anchors rank according to their size and weight, as follows: bower, sheet or stream, and kedje; and a competent authority recommends them in the following order: the Lenox and Rodger for bower, Mitcheson for sheet, and Trotman for a shore anchor.—The anchor adopted by the United States navy is solid with an iron stock, and as a rule its weight is proportionally less than the English standard, our officers preferring a smaller anchor with greater length of chain. The following table gives the relative size of chains to anchors of given weight, and is compiled from the navy regulations on this subject:

Weight of anchor.	Size of chain.
8,000 lbs.	2 1/2 inches.
6,000 "	1 7/8 " "
4,000 "	1 1/2 " "
2,000 "	1 1/4 " "
1,000 "	1 1/8 " "

The following is a reduced table of "Lloyd's Regulations for the Number and Weights of Anchors for Merchant Vessels":

Ship's Tonnage.	Bower.			Bower.			Sheet.			Kedje.
	Bower.	Stream.	Kedje.	Wood Stock.	Iron Stock.	Stream.	Kedje.	Sheet.		
Tons.				Cwt.	Cwt.	Cwt.	Cwt.	Cwt.		
50	2	1	1	3	4	1 1/2	2 1/2	1 1/2		
100	2	1	1	5	7	2 1/2	3 1/2	2 1/2		
250	3	1	1	13	15	5	7	5		
500	3	1	2	23	26	9	12	9		
1,000	3	1	2	35	41	12	16	12		
1,600	3	1	2	43	50	14	18	14		
2,000	4	1	2	47	54	14	19	14		

In addition to these various forms of common anchors, there are numerous devices designed for special service. Among these are the grapnel and mushroom anchors shown in fig. 4. The former is adapted for securing light craft, and the latter—a solid concave

metal plate with central shank—is only used where permanent anchorage is desired, as for light-ships, buoys, &c. The latest novelty is an

FIG. 4.—Grapnel and Mushroom Anchors.

anchor with an elastic shank. The principle of having a spring between the soil and the vessel is evidently excellent, as it is certain that without the natural spring formed by the curve in the chain it could never withstand the sudden jerks from a mass of several hundred tons, though the better place for the spring seems to be on board rather than in immediate contact with the rough sea bottom.

ANCHORET, *Anchorite*, or more properly *Anachoret* (Gr. *ἀναχωρητής*), a person retired from society, especially one who has withdrawn himself with the specific purpose of attaining a higher degree of spirituality. The term is particularly applied to the hermits who began to appear in the Christian church about the 3d century, living in solitude generally in desert places, and not, like the later cenobites or monks, in communities. They often subjected themselves to extreme penances and mortifications. St. Paul the Hermit, St. Simeon Stylites, and St. Anthony of the Desert were among the most celebrated of them, Paul being reckoned the earliest of the solitaries. After the institution of monasticism they gradually disappeared in the West. A synod in 692 ordained that no person should be admitted an anchorite until he had resided three years in a monastery. Hermits are still to be found in the East, unconnected with any convent. Some writers consider Enoch, Elijah, John the Baptist, and Jesus to have been anchorites. The Therapeutæ of Egypt, who were probably derived from the Jewish Essenes, were anchorites, or at least ascetics. The same is true to a degree of the Nazarites of the Old Testament. But so far as Christian anchorites are concerned, they must be referred to the time of the Decian persecution, as the era when they first attained to any historic consideration.

ANCHOVY, a small fish of the genus *engraulis* of Cuvier, the peculiar features of which are the opening of the mouth extending behind the

eyes, and the long sharp head and projecting upper jaw. It is distinguished from the sprat and other similar fishes by its very short anal fin, and the dorsal fin being immediately above the ventral. Anchovies enter the Mediterranean from the sea in enormous shoals in the spring, and deposit their ova along the shores in May, June, and July. They are caught like the herring with nets at night, with the use of lights. Gorgona, a small island west of Leghorn, is a famous place for the fisheries, and it gives its name to the best qualities of the commercial article. Other important fisheries are along the coasts of Provence and Catalonia. As the fish are taken, the bodies, separated from the heads and entrails, are salted and packed in small barrels, and in this state are ready for exportation. Sent to other countries, they are there repacked in bottles. The brine in which they are kept is reddened with ochre and Venetian red, which is supposed to be done for the purpose of concealing the other dirt. Notwithstanding their impurities and the substitution of many inferior fish, anchovies are a favorite relish at the breakfast table with many, being taken out of the bottles and eaten raw. Anchovy sauce has been a favorite condiment from the time of the Romans. They called it *garum*, and prepared it as it is now made, which is by bruising and boiling the fish over a slow fire with melted butter.

ANCHYLOSIS (Gr. *ἀγκύλωσις*, a bending), that condition of a joint in which its natural mobility is greatly impaired or entirely lost. The derivation of the word would imply that the joint is bent, but it is used to designate the abnormal condition in any position. Anchylosis may be true or false. In the former the material which has been produced by the diseased process, and which prevents the proper degree of motion, is bone; in the latter it is fibrous tissue, or the muscles which surround the joint are shortened to such an extent as to curtail movement. In either case the material may be between those surfaces of the bones which help to form the joint (intra-articular), or may lie chiefly or entirely outside (extra-articular). Anchylosis is usually the result of an inflammation in or near the joints affected, though it may occur in cases where the joint has been retained in a fixed position for a considerable length of time, the disease or injury being in a distant part. If a bone be broken, it must be kept fixed in order that it may unite; and to effect this it is usually necessary to render the joint above and that below the fractured part immovable until union has taken place. During this period, if proper precaution be not exercised, the joint may become stiffened, and in this case it is almost always by false anchylosis. This result is more apt to occur if the fracture be very near to, or especially if it implicate, the articulation. When a joint is inflamed, the immobility necessary to cure this condition, and still more the not infrequent partial or complete destruction of those struc-

Anchovy (*Engraulis encrasicolus*).

tures which form it, are frequent causes of ankylosis. This result, though never desirable, is at times unavoidable, and the most favorable termination that can be expected.—The treatment is of three kinds, preventive, precautionary, and remedial. Ankylosis may be prevented by moving the joint at proper times, the parts which surround it being in this way kept from contracting. As regards precautionary treatment, where ankylosis is inevitable, the surgeon should always endeavor to place the part in such a position as that it shall be most useful to the patient; *e. g.*, a nearly straight position for the knee, a bent position for the elbow. To remedy the resulting deformity or inconvenience, the contracted parts may be stretched gradually by proper apparatus, or they may be stretched and ruptured suddenly; and some which refuse thus to yield may in appropriate cases be divided by a narrow-bladed knife passed subcutaneously. The above treatment can be practised only where the ankylosis is of the false kind; if it be true, a portion of the bone at or near the joint may be removed, and the parts be allowed to stiffen in a more convenient position, or an attempt may be made to form a new joint by keeping up motion. Where the limb is useless and inconvenient, it may be advisable to remove it.

ANCIENNE LORETTE, a village of Canada, 7 m. W. S. W. of Quebec; pop. in 1871, 2,333. It is a place of historical interest, as the refuge of a portion of the Huron Indians after they were defeated and driven from the E. shore of Lake Huron, about 1650. There are now about 250 of them, chiefly employed in making moccasins and snow shoes.

ANCILLON. I. David, a French Protestant divine, born in Metz, March 18, 1617, died in Berlin, Sept. 3, 1692. He was the son of a lawyer, and received his first education at a college of Jesuits, who endeavored in vain to convert him to Catholicism. After completing his studies at Geneva, he was pastor at Charenton, and afterward at Meaux (1641-'53) and at Metz (1653-'85). On the revocation of the edict of Nantes he went to Frankfort-on-the-Main, and was afterward pastor in that city, at Hanau, and in Berlin. He wrote *Apologie de Luther, de Zwingle, de Calvin et de Bèze* (Hanau, 1666), and several other small works.

II. Charles, a French author, son of the preceding, born in Metz, July 28, 1659, died in Berlin, July 5, 1715. He graduated as a lawyer in Paris, failed to obtain from Louis XIV. the exemption of the Metz Protestants from the revocation of the edict of Nantes, though the persecutions were somewhat relaxed, and subsequently joined his father in Berlin, where the elector of Brandenburg placed him at the head of the French refugees, and subsequently sent him as minister to Switzerland. After being employed (1695-'99) by the landgrave of Baden-Durlach, the king of Prussia appointed him historiographer and chief of police.

Among his works are *Histoire de l'établissement des Français réfugiés dans les États de Brandebourg* (Berlin, 1690), and *Histoire de la vie de Soliman II.* (Rotterdam, 1706). **III. Ludwig Friedrich**, grandson of the preceding, born in Berlin in 1740, died June 13, 1814. He was pastor of the French community in Berlin, counsellor of the upper consistory, and author of various writings. **IV. Johann Peter Friedrich**, a Prussian statesman and historian, son of the preceding, born in Berlin, April 30, 1767, died there, April 19, 1837. After graduating at the university of Geneva, he was appointed pastor of the French church in Berlin (1790), and professor of history in the military academy (1792). In 1793 he travelled through Switzerland and France. In 1801 he published *Mélanges de littérature et de philosophie*. Two years later followed his most important historical work, the *Tableau des révolutions du système politique de l'Europe depuis le 15^{me} siècle* (afterward translated by himself into German). This was followed by his works *Ueber Staatswissenschaft* (1819), *Ueber Glauben und Wissen in der Philosophie* (1824), and other writings.

ANKARSTROEM, or Ankarström, Johan Jakob, the assassin of Gustavus III. of Sweden, born about 1760, executed at Stockholm, April 29, 1792. The son of a superior officer, he became a page at the court of Gustavus, and subsequently ensign in the royal body guard; but in 1783 he withdrew from military service, and settled into country life. As a partisan of the old aristocratic party he vehemently opposed the measures of the king, who followed up his work, begun on his accession, of restricting the power of the senate and the nobility. He became implicated in the seditious movements of the island of Gothland, and was tried for treason in 1790, but acquitted for want of evidence. The same year he engaged in a conspiracy with General Pechlin, Count Horn, Count Ribbing, Baron Bjelke, Colonel Liljehorn, and other discontented nobles, to kill the king; and on casting lots who should execute the deed, the choice fell upon Ankarstroem. On the night of March 15, 1792, at a masked ball, he shot the king, inflicting a fatal wound. Ankarstroem was at once arrested, tried, convicted, and sentenced, first to be ignominiously flogged, and then to die on the scaffold. He met his fate with great firmness, exulting to the last in the righteousness of his course, and refusing to disclose the names of his accomplices.

ANCLAM. See ANKLAM.

ANCONA. I. One of the four provinces of the department of the Marches, Italy, bounded E. by the Adriatic and traversed by branches of the Apennines, with fertile valleys, and by the small rivers Misa, Esino, and Musone; area, about 740 sq. m.; pop. in 1872, 262,359. Almost the whole province is under cultivation. It is rich in cattle, cereals, hemp, tobacco, wine, oil, and fruit, and produces some silk. **II.** A fortified city and free port, capital of the above province, on the Adriatic, 132 m. N. E. of Rome;

pop. in 1872, 45,741, including about 5,000 Jews and a number of Greeks, Levantines, and Turks. The city is built in the form of an amphitheatre, on the slope of two hills rising from the shores of the Adriatic. It is connected by railways and steamers with all parts of Europe and the East. The annual arrivals of ships are over 1,500, besides steamers. The chief imports are colonial produce, metals, and coals. The principal exports are corn, hemp, bacon, sulphur, and cotton. The coasting trade is also very active. The chief manufactures are woollens, cotton, silk hats, and paper. The port is formed by two moles; one, built by Trajan, is 2,000 feet long, 100 feet wide, and 65 feet above water, and is spanned by the famous arch of Trajan, considered the finest in the world; the other has a triumphal arch constructed by Pope Benedict XIV. from the designs of Vanvitelli. The harbor, defended by several forts,

had fallen into decay and was filling up; but it has recently been dredged and is now rapidly improving. Ancona, notwithstanding its fine quay and a beautiful situation, has the disagreeable appearance of a Levantine city, with dirty and narrow business streets, though with a number of good residences along the quay. The cathedral, situated on a promontory, has a remarkable porch, a cupola reputed to be the most ancient in Italy, and fine marble pillars. The churches of San Domenico and San Francisco contain pictures by Titian; and there are also notable pictures in the other churches, most of those in St. Agostino being by Lilio, known as Andrea di Ancona. The English residents worship in the Free Church of Scotland chapel.—The city is believed to have been founded by a colony of Syracusans in the time of Dionysius the Elder. Trajan used the port as a military station. After having been gov-

Ancona, with the Arch of Trajan.

erned by Romans and Lombards, and devastated by Saracens on several occasions, particularly in the 10th century, Ancona remained for a considerable period independent until 1532, when Clement VII. annexed it to the Papal States. In 1832 the citadel was seized by the French as a demonstration against the Austrians, who had occupied the insurgent Marches; but the papal authorities continued to preside over the civil administration. The French occupation lasted till 1838. In 1849 the city surrendered to the Austrians, who evacuated it after the battle of Magenta, fought June 4, 1859. Gen. Lamoricière, commander of the Papal troops, after his defeat at Castel-fidardo, surrendered here to the Italians, Sept. 29, 1860. Ancona became part of Victor Emanuel's possessions Dec. 17, 1860.

ANCRE, Concino de' Concini, marshal and marquis d', a Florentine adventurer and prime minister of France, shot in Paris, April 24, 1617. He was the son of a notary, and went to France in 1600 in the suite of the bride of Henry IV., Maria de' Medici, one of whose attendants, Leonora Dori or Galigai, was his wife. With the aid of this woman, who was the daughter of Maria's nurse, he soon rose to high favor at court. He fomented the disagreements between the king and queen, and when the latter became regent on Henry's death he was recognized as the prime favorite of the palace. He bought the marquise of Ancre, and, though he had never been a soldier, was created marshal of France. The resentment of the country at his sudden elevation and his insolence was aggravated by his

raising an army of 7,000 men, whom he kept at his own disposal and his own expense. Appointed prime minister by the queen regent, he kept the young king Louis XIII. under a restraint that was little better than captivity; and that prince before he was 17 years old gave his assent to a conspiracy formed by his favorite, De Luynes (a man whose fortunes the marshal himself had made), to put the minister to death. The murder was committed before the Louvre by L'Hôpital-Vitry, a captain of the royal guards, Du Hallier, and Perray; and Louis, presenting himself afterward at the window, cried out, "Thanks to you, I am now king." Vitry was made marshal of France. The body of the murdered man, after a secret burial, was dug up by the mob, dragged to the Pont Neuf, gibbeted, and torn into a multitude of pieces, which were then sold to the infuriated people. His widow, who is said to have been the first instrument of Richelieu's fortunes, was accused of Judaism, corruption, and sorcery, and burnt on the Place de Grève, July 8, 1617. She displayed great firmness, and declared that the only sorcery she had employed toward the queen was "the power of a strong mind over a weak one."

ANCUS MARCIUS, the fourth king of Rome, said to have been the grandson of Numa, and to have reigned from 640 to 616 B. C. He revived the religious ceremonies which his grandfather had established, but which had fallen into desuetude. He waged successful wars against the Latins, took many of their cities, and transported their inhabitants to Rome. He founded a colony at Ostia, erected a fortress on the Janiculum, and caused several other works to be constructed, which added to the strength and security of his capital.

ANCYRA (now *Angora*), an ancient city of Asia Minor, originally in Phrygia, said to have been built by Midas, and to have derived its name from an anchor found on the place where it stood. It was enlarged by Augustus, was made the capital of the province of Galatia, and became a principal depot of the Romans for the productions of the East. A copy on marble blocks, erected by the inhabitants of Ancyra, of the inscriptions of Augustus's Roman bronze tablets, which was discovered by Tournefort, and has since been often exposed by antiquaries, is known under the name of *Monumentum Ancyranum*.

ANDALUSIA (Span. *Andalucía*, originally *Vandalusia*, from the Vandals who settled there in the 5th century; in antiquity, *Bætica*), the most southern grand division of Spain, lying between lat. 36° and 38° 40' N., and lon. 1° 30' and 7° 30' W.; area, 27,153 sq. m.; pop. in 1867, 3,200,944. It is bounded N. by Estremadura and New Castile, E. by Murcia, W. by Portugal, S. W. by the Atlantic, and S. and S. E. by the straits of Gibraltar and the Mediterranean. Its chief river is the Guadalquivir, its mountain ranges the Sierra Nevada in the south and Sierra Morena in the north.

Mulhacen, a peak of the former, is 11,678 feet high. The climate is mild, the soil generally fertile, and the country level where not mountainous. The vegetation partakes both of the European and African character. In the south cotton and sugar cane are cultivated. These, with grain, olives, wines, figs, silk, cochineal, wool, and a fine breed of horses, are its chief products. Gold, silver, copper, iron, lead, antimony, sulphur, coal, mercury, vitriol, serpentine marble, and alabaster are found. The mines, rich in antiquity, are now much neglected. The country is parcelled out into vast estates, belonging to the crown, the clergy, and large landed proprietors. Agriculture is in a very backward state. A large part of the plains is devoted to pasturage. The manufactures, once important, have greatly declined; the principal are those of woollens, silk, and leather. The chief cities are Seville, the seat of the captain general, Cadiz, Cordova, Granada, Jaen, Malaga, Almeria, and Huelva, each the capital of a province named after it. The chief ports are Cadiz and Gibraltar. The Andalusians are a mixed race, descended from Phœnicians, Carthaginians, Romans, Goths, Vandals, and Moors, all of which nations are conspicuous in the checkered history of the country. Physically they retain many of the peculiarities of the last-named people. They are animated and naturally intelligent. Trajan, the Senecas, and Lucan were natives of Andalusia. In the middle ages it was the flourishing home of Moslem and Jewish learning; in modern times it has given Spain some of its most illustrious statesmen, painters, and authors.

ANDAMAN ISLANDS, a long, narrow group of small islands in the E. part of the bay of Bengal, in lon. 92° 50' E., and between lat. 10° and 14° N., about 150 m. S. by W. of Cape Negrais, 100 m. N. of the Nicobar group, and 350 m. W. of the Tenasserim coast; area, about 3,000 sq. m.; pop. in 1870, 9,630. They include the North, Middle, South, and Little Andaman islands, with a number of islets, and are all densely wooded, producing ship timber and ornamental woods. The 1,000 natives are a diminutive and barbarous people, who seem to be distinct from all other known races, and whose language has no apparent affinity with any other tongue spoken in India or the Indian islands. They are seldom more than five feet in height, have protuberant bellies, slender limbs, woolly hair, thick lips, flat noses, and small red eyes. Their color is a deep black. They wear no clothing except a thick plaster of mud, intended to resist the attacks of insects. They live in the most wretched huts, subsist by fishing, never till the ground, have no implements that will resist fire, paint their heads with red ochre, will hold no intercourse with strangers, and are supposed to worship the sun and moon. The British formed a settlement at Port Cornwallis on the largest of the islands in 1793, with the purpose of making a penal colony for convicts from Bengal, but

abandoned it three years later on account of the unhealthiness of the climate. After that the group was seldom visited till 1858, when Port Blair on one of the islands was selected as a penal settlement. Here, on Feb. 8, 1872, the earl of Mayo, viceroy of India, was assassinated by a Mohammedan convict, immediately after landing at night for a visit of inspection.

ANDELYS, Les, a town of France, in the department of Eure, on the Seine, 18 m. S. S. E. of Rouen. It properly consists of two towns, Grand Andely on the Gambon and Petit Andely on the Seine; pop. in 1866, 5,161. It is the birthplace of Turnebus and Poussin. Near it was the celebrated fortress Château Gaillard, and a convent founded by St. Clotilde.

ANDENNE, a town of Belgium, in the province of Namur, near the right bank of the Meuse, 10 m. E. of Namur; pop. in 1866, 6,278. It has a convent of the Beguines, and manufactories of pipes and earthenware.

ANDERLECHT, a town of Belgium, in the immediate vicinity of Brussels, of which it may be regarded as a suburb; pop. in 1866, 11,663. At Anderlecht Dumouriez defeated the Austrians on Nov. 13, 1792.

ANDERLONI, **I. Pietro**, an Italian engraver, born at Santa Eufemia, near Brescisa, Oct. 12, 1784, died in Milan, Oct. 13, 1849. After preparatory studies under his father, who was himself an engraver, he entered the school of Longli at Milan, of which he subsequently became director. His most admired pieces are portraits of Da Vinci, Canova, and Peter the Great; his "Moses with the Daughters of Jethro," after Poussin; his "Virgin," after Raphael; and his masterpiece, "The Woman taken in Adultery," after Titian. **H. Faustino**, brother of the preceding, an engraver of Pavia, born in 1766, died Jan. 9, 1847. Among his works are a portrait of Herder, a Magdalen after Correggio, and a "Holy Family" after Poussin.

ANDERSEN, **Hans Christian**, a Danish author, born in Odense, April 2, 1805. His father was a shoemaker in needy circumstances, but possessing literary taste. Andersen's scanty education was chiefly acquired at a charity school. At nine years of age he lost his father, and shortly afterward was taken into the house of the widow of a clergyman, where he was engaged to read aloud to the family. After a short sojourn in a manufactory, where he was ill-treated by the workmen, whom he had amused by singing and reciting to them passages from Holberg, he returned home, and for a while led an inactive life. He possessed an agreeable voice, and his mother was advised to send him to the theatre. She determined, however, to make a tailor of him, but before his apprenticeship commenced he obtained permission to go to Copenhagen and witness the performance of a play. Accordingly, in 1819 he found himself in that city with 10 rix dollars in his pocket, and sought to get an engagement at the theatre in some humble capacity. He was rejected on account of his awkward-

ness and ignorance, but soon afterward presented himself to Professor Siboni, director of the royal conservatory, who received him with kindness, and caused him to be instructed as a singer for the stage. At the end of half a year his voice, which was in the transition state, failed him. He then applied for assistance to the poet Guldberg, the brother of a former patron in Odense, by whose aid he was enabled to struggle on for a few years, sometimes employed in the theatre and sometimes studying. During this period he wrote some tragedies which excited the attention of Oehlenschläger and others, but which he was unable to have produced upon the stage. Councillor Collin, a benevolent and clear-sighted man, having become director of the theatre, procured his admission free of expense into one of the government schools. This was the turning point in Andersen's life; he embarked in this new career with enthusiasm, was admitted into the royal college of Copenhagen, and while completing his studies there produced in 1829 his first work in print, entitled "A Journey on Foot to Amak," which was received with extraordinary favor, and gained him the acquaintance of some of the most influential people in Copenhagen. Some volumes of poems which succeeded increased his reputation. Oehlenschläger, Ingemann, and other friends having procured a royal stipend to enable him to travel, in 1833 he visited Italy, his impressions of which he has recorded in his novel, "The Improvisatore," which stands unrivalled as a picture of scenery and manners in southern Europe; and he has since travelled extensively throughout Europe and the East. His next novel, "O. T.," describes life in the north, and "Only a Fiddler" some of the most striking scenes in his early struggles. Among his other works are "Fairy Tales," "Picture Book without Pictures," "Travels in the Hartz Mountains," "A Poet's Bazaar," "Ahasverus," "New Fairy Tales," and some volumes of poetry, dramas, fairy comedies, and texts for operas. In 1846 he visited England, where he made many friends, and in 1849 wrote one of his longest works, "The Two Baronesses," in the English language. His works reflect his own kindly and open disposition, and are marked by humor, invention, and a poet's enthusiasm. His fairy tales for children have been read with delight in every modern language. He is also an admirable public reader of his own works, enjoying in this respect in Denmark a fame equal to that of Dickens in England and America. In 1845 he received a royal annuity which placed him in comfortable circumstances for the remainder of his life. The series of translations from his works by Mary Howitt and others has introduced him to a large circle of admirers in England and America. The first complete edition of his works in English was published in 1870-'71 in New York, in 10 vols. 8vo, including "The Story of My Life," an autobiography.

ANDERSON. I. A N. W. county of South Carolina, separated from Georgia by the Savannah river, bounded N. E. by the Saluda and drained by a number of smaller streams; area, 800 sq. m.; pop. in 1870, 24,049, of whom 9,593 were colored. The Greenville and Columbia and the Blue Ridge railroads traverse the county. The surface is uneven; the soil fertile and well cultivated. The productions in 1870 were 77,169 bushels of wheat, 409,688 of corn, 34,213 of oats, 13,225 of sweet potatoes, 162,842 lbs. of butter, 15,397 of wool, and 5,274 bales of cotton; value of animals slaughtered, \$189,982. There were 984 white and 309 colored children attending school. Capital, Anderson. **II.** An E. central county of Texas, bounded W. by the Trinity river, and touching the Neches river on the east; area, 900 sq. m.; pop. in 1870, 9,229, of whom 4,436 were colored. About two thirds of the county is timbered. The surface is rolling and the soil fertile. In 1870 the county produced 177,285 bushels of corn, 22,136 of sweet potatoes, 4,016 bales of cotton, and 49,381 lbs. of butter. Iron ore is abundant. There are about 20 churches and the same number of schools. Capital, Palestine. **III.** A N. E. county of Tennessee, traversed by Clinch and Powell's rivers; area, 600 sq. m.; pop. in 1870, 8,704, of whom 928 were colored. On its northwestern border is Cumberland mountain, and on the southeast rises Chestnut ridge, between which two ranges lies a deep fertile valley, well watered and abundantly stocked with timber. Coal is found in various parts of the county. At Estabrook are salt and sulphur springs. The chief productions in 1870 were 22,932 bushels of wheat, 262,664 of corn, and 73,441 of oats. Capital, Clinton. **IV.** A N. central county of Kentucky, bounded E. by the Kentucky river, and intersected by Salt river; area, 300 sq. m.; pop. in 1870, 5,449, of whom 698 were colored. The surface is level or gently undulating; the soil generally productive. The productions in 1870 were 35,340 bushels of wheat, 300,963 of corn, 33,004 of oats, 19,539 of rye, 15,165 lbs. of tobacco, 18,425 of wool, and 112,341 of butter. Capital, Lawrenceburg. **V.** A S. E. county of Kansas, drained by Potawatamie creek, a branch of the Osage river; area, 576 sq. m.; pop. in 1870, 5,220. The productions in 1870 were 35,769 bushels of wheat, 206,989 of corn, 77,779 of oats, 12,913 lbs. of wool, and 93,485 of butter. Capital, Garrett.

ANDERSON, Alexander, the first wood engraver in America, born in New York, April 21, 1775, died in Jersey City, N. J., Jan. 17, 1870. He was the son of a Scotch printer, who just before the outbreak of the revolution published in New York a republican newspaper, "The Constitutional Gazette," so strongly opposing British rule that when Howe's army entered the city he was obliged to take refuge in Connecticut. At the age of 12 Anderson made his first attempt at engraving on small copper and

type-metal plates, having obtained his only instruction by watching jewellers and other workmen. Among his early engravings were some copies of anatomical figures, and his interest in subjects of this kind induced him to begin the study of medicine. He took his doctor's degree at Columbia college in 1796, writing an able thesis on "Chronic Mania," but soon began to devote himself to art studies, finding his first regular employment in the illustration of a little book, "The Looking-Glass for the Mind." Hearing of the method of Bewick, the English engraver, he began to use boxwood blocks, though for some years employing copper in the greater part of his work. He invented his own tools for wood engraving, since none existed in America at the time he began the experiment. After 1812 he engraved only upon wood, and attained great skill. He illustrated many standard works; among the earliest was the first edition of Webster's spelling-book. He was for many years employed in illustrating the American tract society's publications, retiring in 1865, at the age of 90, till which time he had retained his skill and mental powers almost unimpaired.

ANDERSON, Sir Edmund, an English judge, born in Lincolnshire about 1540, died Aug. 1, 1605. He was made chief justice of the common pleas in 1582, and distinguished himself by his zeal for the established church and his harshness toward dissenters. He was one of the commissioners for the trial of Mary queen of Scots, and afterward of Raleigh. His "Reports of Cases argued and adjudged in the time of Queen Elizabeth, in the Common Bench" (fol., London, 1644), and "Resolutions and Judgments on the Cases and Matters agitated in all the Courts of Westminster in the latter end of the Reign of Queen Elizabeth" (4to, London, 1655), are much esteemed.

ANDERSON, James, a Scottish antiquary and lawyer, born in Edinburgh, Aug. 5, 1662, died April 3, 1728. In 1705 he published "An Essay showing that the Crown of Scotland is Imperial and Independent," in answer to a pamphlet which had appeared a short time before. For this he received the thanks of the Scottish parliament, besides a present in money, and a commission to collect and publish ancient documents illustrative of the national independence. Soon after the union of the two kingdoms he removed to London, where he employed himself in literary labors and in endeavoring to obtain a recognition of his claims on the government; and from 1715 to 1717 he was postmaster general of Scotland. He published "Collections relating to the History of Mary, Queen of Scotland" (4 vols. 4to, 1727-'8). His "Royal Genealogies, . . . from Adam to these Times," appeared after his death (1732), as also his great work, *Selectus Diplomatum et Numismatum Scotiæ Thesaurus* (1739), edited by Ruddiman.

ANDERSON, James, a Scottish writer on agriculture, political economy, and natural science,

born at Hermiston, near Edinburgh, in 1739, died Oct. 15, 1808. At the age of 15, having lost his parents, he assumed the charge of the paternal farm, and he was still very young when he introduced among the farmers of his neighborhood the two-horse plough without wheels. In 1763 he took a lease of 1,300 acres of nearly wild land in Aberdeenshire, and in 1771 contributed to the "Edinburgh Weekly Magazine" a series of essays on planting, which were in 1777 collected and published separately. In 1780 he received from the university of Aberdeen the degree of doctor of laws, and in 1783 removed to Edinburgh. In 1784 he was employed by the government to make a survey of the Hebrides and the western coast of Scotland, with a view to the improvement of the fisheries. In 1791 he established a literary and scientific periodical called the "Bee," designed especially for the young. Having removed to the neighborhood of London in 1797, he commenced in April, 1799, a periodical entitled "Recreations in Agriculture," which continued until March, 1802, and of which he wrote the most valuable papers.

ANDERSON, John, a Scottish professor, founder of the Andersonian university at Glasgow, born in the parish of Roseneath, Dumbartonshire, in 1726, died Jan. 13, 1796. In 1756 he was appointed professor of oriental languages in the university of Glasgow, and in 1760 professor of natural philosophy. He established a gratuitous course of popular scientific lectures. By his will he directed all his property to be applied to found an institution for the education of the poorer classes. Though this institution was conducted first on a small scale, it has since increased its means of usefulness, and now has 14 professors and lecturers, with courses of instruction in surgery, chemistry, institutes of medicine, materia medica, anatomy and physiology, medical jurisprudence, natural philosophy, botany, the classics, and Hebrew, French, and music. In 1786 Dr. Anderson published "Institutes of Physic" for popular use, which passed through five editions in ten years.

ANDERSON, Martin Brewer, LL. D., an American educator, born in Brunswick, Me., Feb. 12, 1815. He graduated in 1840 at Waterville college, Me., where, after studying about a year in the theological seminary at Newton, Mass., he became a tutor of Latin, Greek, and mathematics. In 1843 he was appointed professor of rhetoric, but continued to give instruction in Latin, and organized and taught a course of modern history. In 1850 he resigned his professorship, and became proprietor and editor of the "New York Recorder," a weekly Baptist journal. In 1853 he was called to the presidency of the then newly founded university of Rochester, which position he still holds (1872). In 1868 he was offered the presidency of Brown university at Providence, R. I., but declined to accept it. He has preached much, though never ordained as a clergyman, and

has contributed literary and philosophical articles to various public journals.

ANDERSON, Robert, an officer of the U. S. army, born at "Soldiers' Retreat," near Louisville, Ky., June 14, 1805, died at Nice, France, Oct. 26, 1871. He graduated at West Point in 1825, entered the 3d artillery, and served in the "Black Hawk war" of 1832. In 1835-7 he was instructor of artillery at West Point, afterward served in the Florida war, and in May, 1838, became assistant adjutant general on the staff of Gen. Scott. In 1841 he resigned this appointment on his promotion to a captaincy. He accompanied Gen. Scott to Mexico in 1847, and was severely wounded at Molino del Rey. In 1857 he was promoted to be a major in the 1st artillery. On Nov. 20, 1860, he assumed command in Charleston harbor, S. C. On the night of Dec. 26, expecting an attack by the authorities of South Carolina, he removed his small garrison from Fort Moultrie to the stronger Fort Sumter, where during the next 3½ months he was closely invested by the confederate troops. On April 13 he evacuated the fort after a bombardment of nearly 36 hours, during which he lost none of his men by the fire of the enemy, marched out with his 70 men with the honors of war on the 14th, and sailed the next day for New York. In May, 1861, he was appointed brigadier general in the U. S. army, and commander of the department of the Cumberland, but in consequence of failing health he was soon relieved, and afterward breveted major general in the regular army, and retired from service. In 1868 he went to Europe for the benefit of his health. He translated and adapted from the French "Instructions for Field Artillery, Horse and Foot, arranged for the Service of the U. S. Army," and "Evolutions of Field Batteries of Artillery," now used by the war department.

ANDERSONVILLE, a village of Sumter co., Ga., on the Southwestern railroad, 62 m. S. of Macon; pop. in 1870, 1,346. It was during the war the seat of a Confederate States military prison, established by Capt. W. S. Winder, Nov. 27, 1863, at which time the population of the neighborhood did not exceed 20 persons. The site selected was a pine and oak grove of about 22 acres, on the side of a hill of red clay, 1,600 feet E. of the railroad. Near the base of the declivity was a stream of unwholesome water about 5 feet wide and not more than 6 inches deep. The trees were cut down and the enclosure was surrounded by a strong stockade 15 or 18 feet high. It was originally a parallelogram, 1,010 feet long by 779 feet wide, but in the summer of 1864 its length was increased to 1,620 feet. At the distance of 120 feet, surrounding the inner enclosure, was another palisade of rough pine logs, and between the two were sentry boxes overlooking the interior. A cordon of connected earthworks mounted with 17 guns, commanding the entire prison, surrounded the outer palisades. A wooden railing about 3

feet high around the inside of the stockade, and at an average distance of 19 feet from it, constituted the "dead line," prisoners passing which were summarily shot. The stream above mentioned passed from W. to E. through the enclosure, and furnished the only water for washing accessible to the prisoners. Many acres bordering the stream on either side were trodden by the feet of the prisoners into a deep and filthy mire. Deducting the quagmire thus formed, about 300 feet wide, and the space cut off by the "dead line," the remaining space before the enlargement comprised about 12 acres, giving to each prisoner when the number reached 30,000 an average area of about 17 square feet. A small shed, covered but not enclosed, furnished the only protection from the inclemency of the weather. A few wells were sunk in the prison, and there were also a few springs. A second enclosure, 925 feet long and 400 feet wide, similar to the prison, was constructed in June, 1864, for a hospital; with the exception of a few old tents, it contained nothing but long sheds made of poles, with roofs of pine boughs or planks, and without sides. The bakery was within the two lines of palisades, and the cook house was 200 yards outside. On the high land overlooking the prison were a two-story building for the confederate officers and men, and the huts for the guards, who numbered from 3,000 to 5,000. Near the railroad station a stockade measuring 195 by 108 feet was constructed, and for a while used as a prison for officers; but they were subsequently confined at Macon. Between the graveyard and the stockade stood a small hut in which nine bloodhounds were kept. The graveyard was situated about 300 yards N. W. of the stockade. Trenches varying in length from 50 to 100 yards having been dug, the bodies were laid in rows of 100 to 300 and covered with earth. At the head of each body a wooden stake was planted by the federal soldiers detailed to bury their companions, and each stake bore a number corresponding with a similarly numbered name upon the hospital record. The first detachment of federal prisoners was received at the Andersonville prison Feb. 15, 1864. Soon afterward John H. Winder, a brigadier general in the confederate army, assumed command of the post, with his son, W. S. Winder, as adjutant. The superintendence and management of the prison were assigned to Henry Wirz, a Swiss by birth. The following exhibit from the prison records shows the number and mortality of prisoners:

Total number received at prison.....	49,455
Largest number in prison at one time, Aug. 9, 1864.....	33,006
Total number of deaths as shown by hospital register.....	12,462
" " in hospital.....	8,735
" " in stockade.....	3,727
Percentage of deaths to whole number received.....	26
" " to number admitted to hospital.....	69 1/2
Average number of deaths for each of the 13 months.....	95 5/8
Largest number of deaths in one day, Aug. 23, 1864.....	97
Cases returned from hospital to stockade.....	3,469
Total number of escapes.....	823

DATE.	Total number at end of each month.	Number of deaths.	Average daily deaths.	Ratio of deaths to living.	Per cent. of deaths per month based on number in prison each month.

In August, 1864, Dr. Joseph Jones, professor of chemistry in the medical college of Georgia, under the direction of the surgeon general of the confederacy, was sent to Andersonville to investigate the nature and cause of the sickness prevalent there, "for the benefit of the medical department of the Confederate States armies." The order, dated at Richmond, Aug. 6, 1864, recited that "the field of pathological investigation afforded by the large collection of federal prisoners in Georgia is of great extent and importance, and it is believed that results of value to the profession may be obtained by a careful investigation of the effects of disease upon the large body of men subjected to a decided change of climate and the circumstances peculiar to prison life." Dr. Jones reported that scurvy, diarrhoea, dysentery, and hospital gangrene were the prevailing diseases; that there were few cases of malarial fever and no well marked cases of typhus or typhoid fever. The absence of the different forms of malarial fever was accounted for by the supposition that the artificial atmosphere of the stockade, crowded densely with human beings and loaded with animal exhalations, was unfavorable to the existence and action of the malarial poison. Subsequently, at the suggestion of Gen. Winder, an investigation was made by Dr. G. S. Hopkins and Surgeon H. E. Watkins, who reported the general causes of diseases and mortality as follows: "1. The large number of prisoners crowded together. 2. The entire absence of all vegetables as diet, so necessary as a preventive of scurvy. 3. The want of barracks to shelter the prisoners from sun and rain. 4. The inadequate supply of wood and

good water. 5. Badly cooked food. 6. The filthy condition of the prisoners and prison generally. 7. The morbid emanations from the branch or ravine passing through the prison, the condition of which cannot be better explained than by naming it a morass of human excrement and mud." Early in May, 1864, a report upon the condition of the prisoners was made by the confederate surgeon E. J. Eldridge, pursuant to instructions of Gen. Howell Cobb, and on July 5 an inspection report was submitted by Col. Chandler of the confederate war department. In these reports the sickness and mortality of the prisoners were attributed to the bad condition of the prison and its management. In August, 1865, a special military commission was convened by the secretary of war to try Wirz. The indictment charged him with injuring the health and destroying the lives of soldiers confined as prisoners at Andersonville, by subjecting them to torture and great suffering, by confining them in unhealthy and unwholesome quarters, by exposing them to the inclemency of the winter and the dews and burning sun of the summer, by compelling the use of impure water, and by furnishing insufficient and unwholesome food; also for establishing the "dead line," and ordering the guard to shoot down any prisoner attempting to cross it; for keeping and using bloodhounds to hunt down prisoners attempting to escape; and for torturing prisoners by confining them within the "stocks." Wirz, having been found guilty on these charges, was hanged Nov. 10, 1865. After the close of the war the cemetery at Andersonville was arranged by Col. Moore of the U. S. quartermaster's department, pursuant to orders from the secretary of war. The stakes were removed and neat head boards, inscribed in black letters, with the names of the dead were substituted. The bodies in the trenches were found to be from two to three feet below the surface, and in some instances, where the rain had washed away the earth, but a few inches. They had been buried without coffins or the ordinary clothing, and not more than 12 inches in width had been allowed to each body. With the aid of the hospital record, 12,461 graves were identified and marked with tablets giving the number, name, rank, regiment, company, and date of death of each person; and 451 graves bore the inscription "Unknown U. S. Soldier." The cemetery was carefully laid out in walks and adorned with trees.

ANDERSSEN, Adolph, a German chess player, born in Breslau, July 6, 1818. He was a teacher of mathematics, acquired in Berlin a high reputation as a chess player, and attended in 1851 the chess tournament in London, where he defeated Stamiton and other English celebrities. In December, 1858, he was defeated in Paris by Paul Morphy; but in 1862, at the second London chess tournament, he obtained the highest prize. He is the author of many original outlines of games and of writings on

the theory of chess, published in the Leipzig *Schachzeitung*.

ANDERSSON, Carl Johan, a Swedish traveller, born in the province of Wernmland in 1827, died in the territory of the Ovacnambi, S. W. Africa, July 5, 1867. He was the natural son of Mr. L. Lloyd, an English sportsman residing in Sweden. In 1849 he went to England, and the next year joined Francis Galton in a journey to the territories of the Damaras and the Ovambos, S. W. Africa. He continued his explorations alone in 1853-'4, and published after his return to England (1855) "Lake Ngami, or Explorations and Discoveries during Four Years' Wanderings in the Wilds of Southwestern Africa." Revisiting Africa in 1856, he made a second journey to Lake Ngami (1858) in company with Mr. Green, an English elephant hunter, and found his way up the Okavango, through the territory of the Ovambo, one of the principal red tribes of Herrevo land, which had never been visited by a European excepting by the German missionary Hugo Hahn. He published in London in 1861 a work on the Okavango river. Returning to Herrevo land by way of Walfish bay and the Zwachaub river, he married Miss Aitchison of Cape Town, and devoted himself at Otjimbingue, near Ondongo, to agriculture and commerce. During the war with the Damara and Namaqua tribes he was repeatedly despoiled by the latter, and finally so seriously wounded that he had to be removed to Cape Town. During his illness he studied ornithology and prepared materials for an illustrated fauna of S. W. Africa. Barely recovered, he set out again in May, 1866, with a young Swede, on an expedition to the Cuncne, with a view of establishing commercial intercourse with the Portuguese settlements N. of that river, and came within sight of the long-sought stream; but, too feeble to cross it, he had to retrace his steps and died on the home journey.

ANDERSSON, Nils Johan, a Swedish botanist, born Feb. 20, 1821. He made a voyage round the world in the Swedish frigate *Engenie* in 1851-'3, and published *Verldsomsegling* (3 vols., Stockholm, 1853-'4). He also wrote on Scandinavian botany. Since 1856 he has been professor at Stockholm, and superintendent of the botanical collection of the academy of sciences.

ANDES, the range of mountains which extends along the northern and western coasts of South America, from the southern extremity of the continent to the Caribbean sea. It is the most compact mountain system in the world. Skirting the Pacific shore for nearly 4,500 m., with a mean elevation of 12,000 feet and varying in breadth from 40 to 350 m., it covers with its base a surface of more than half a million square miles. Nowhere else does nature present such a continuous, well defined, and lofty chain. It is in strong contrast with the broken and straggling systems of Europe and North America. The Himalayas surpass the Andes in extreme altitude, but as they are situated beyond the tropics and destitute of

volcanoes, they do not present that inexhaustible variety of phenomena which characterizes the latter. Though presenting one continuous axis, the Andean range consists of several members, known by the names of the countries in which they occur. The Patagonian section is a single narrow range of moderate elevation, but ascending in several points (Mt. Darwin, Mt. Stokes, and the volcanoes of Yantéles and Minchinmadiva) to 6,400 and 8,000 feet. It begins in a group of mountainous islands, the archipelago of Tierra del Fuego; and, indeed, the western side throughout its whole length is penetrated by narrow inlets or arms of the sea and bordered by a series of rugged islands. This Pacific side, exposed to the prevailing winds, is of barren rock; but the eastern slope is covered with forests of beech (*Fagus betuloides*), which reach up to 1,000 or 1,500 feet above the sea level; and beyond this succeeds a belt of dwarfed alpine plants and peat mosses, which continues to the height of 3,500 or 4,000 feet, the limit of perpetual snow. Almost every arm of the sea, says Darwin, which penetrates to the interior higher chain, not only in Tierra del Fuego, but on the coast for 650 m. northward, is terminated by tremendous and astonishing glaciers. Great masses of ice frequently fall from these icy cliffs, and the crash reverberates like the broadside of a man-of-war through the lonely channels. The glacier furthest from the pole which comes down to the sea, surveyed during the voyages of the Adventure and Beagle, is in lat. $46^{\circ} 50' S.$, in the gulf of Peñas.—As the Andes enter Chili they begin to recede from the ocean, and a fertile belt of country intervenes, which in lat. 36° is about 100 m. wide. They still form one immense ridge, but they gain in height and breadth. Though in mean elevation they are inferior to the Andes of the north, they yet contain the gigantic Aconcagua, the culminating point of the whole system, and the highest mountain in the new world. It is frequently called a volcano, but it shows no trace of modern igneous origin, although it is porphyritic. Its height was computed by Capt. Beechey from its angle of elevation at Valparaiso to be 23,910 feet; but the more exact measurement of M. Pissis makes it 22,422. Other Chilean peaks are Tupungato, Antuco, Villarica, Chillan, Maypu, and Osorno, some of which, if not all, are volcanic. The snow line in the latitude of Valparaiso is about 15,000 feet above the sea. "To this line," Darwin observes, "the even summits of the range seemed quite parallel. Only at long intervals a group of points or a single cone showed where a volcano had existed or does now exist. Hence the range resembled a great solid wall, surmounted here and there by a tower, and making a most perfect barrier to the country."—The Bolivian Andes extend from about lat. 24° to $15^{\circ} S.$ For some distance there is but one undivided range as in Chili, between which and the Pacific is the vast desert of Atacama, doubtless the bed

of an ancient sea. At the mountain knot of Alturas de los Lipes, lat. 22° , the chain separates into two great longitudinal ridges, called the Cordillera of the coast and the Cordillera Real, which enclose the wonderful table land of Desaguadero, the Thibet of the new world. This high valley, elevated 13,000 feet above the sea, extends 500 m. in length and from 30 to 60 in breadth along the top of the Andes. It is so completely walled in that the streams have no apparent outlet, but meet in Lake Titicaca. The surface of this lake is 12,846 feet above the Pacific. It is the largest fresh-water accumulation in South America, covering 4,600 sq. m. and having a depth of at least 120 fathoms. The Rio Desaguadero connects it with the Laguna Aullagas, 180 m. S., which is about 50 feet lower than Titicaca. The valley enjoys a temperate climate, but it is treeless and cultivation is limited. Yet large cities have flourished at this altitude. Potosí, famed for its silver mines and for being the most elevated city on the globe, two centuries ago contained 150,000 inhabitants. Its altitude is 13,330 feet. The cerro on which it is situated is honeycombed by mining operations, over 5,000 *boca-minas* being visible. To the N. E. of it is Chuquisaca or Sucre, the capital of Bolivia, in the midst of cultivated fields. La Paz, a few leagues from the southern extremity of Lake Titicaca, is situated in a *quebrada*, or ravine, 620 feet below the lake, and still over 12,000 feet above the sea. The water that flows through the quebrada of La Paz winds around the volcano of Illimani, and, flowing northward and uniting with other branches, becomes with them one of the great tributaries of the Amazon. Nine fine bridges cross this ravine in the city. The Cordilleras run parallel to each other, from 200 to 300 m. distant; the eastern range has a mean elevation of 13,500 feet, and the western 14,800. They are united at various points by enormous transverse mountain dikes or knots. The highest summits in the coast range are Sahama, 22,350 feet; Parinacota and Gualatieri, 22,000 each; Pomarape, 21,000; and the active volcano Arequipa, 20,300. The loftiest peak in the Cordillera Real is that of Sorata, 21,286 feet; and near by is its rival, Illimani, only 100 feet lower. The Pacific slope of this section of the Andes is sandy and barren. In a day's journey into the interior from the port of Iquique in Peru, not a sign of vegetation is met with except lichens strewed loosely upon the sand with nothing to attach them to the surface; nor is the solitude of the desert interrupted by any living thing, bird, beast, or insect, save the occasional train of cargo mules between the coast and the nitrate of soda mines, and the vultures that hover over them, or settle down to feed upon their prey broken down and left behind. The salts of soda (common salt, and the nitrate with some sulphate) are intermixed with the sand, forming hard incrustations, which, though highly attractive of moisture, find in this dry climate not enough of it to cause them to de-

liqueesc. Where worked, at a distance of about 40 m. from the coast, they are in a hard stratum, between 2 and 3 feet thick, found just beneath the surface, and extending along the margin of a great basin or plain for 150 miles. —The Bolivian plateau terminates in the knot of Vilcañota, where the Cordilleras unite, but again diverge as they traverse Peru, and at the same time change from a meridional to a north-westerly course. They stand over 100 miles apart, and bound the diversified plain of Cuzco, a populous and fertile region. Though under the burning sun of the tropics, this region, the territory of the ancient incas of Peru, enjoys the climate and fruits of the temperate zone. Through the range of the mountain valleys, extending from Potosi in Bolivia in a north-westerly direction, taking in the lakes of Aullagas and Titicaca, and the river Desaguadero, which connects them, and reaching beyond Cuzco, are still to be found the ruined works of the ancient inhabitants, the evidences of their high degree of civilization. These are the wonderful roads which Humboldt in his *Vues des Cordillères* speaks of as among the most useful and stupendous works ever executed by man. They passed over the snowy summits of the sierras, through the mountains by tunnels cut in the solid rock, over the precipices by steps, and the awful *quebradas* (or chasms) and rivers by solid masonry, or by bridges swung by osier ropes. With the same bold engineering, their aqueducts for irrigating the dry soil of the valleys brought water for hundreds of miles from distant sources in the mountains. In these valleys, the grains of the temperate latitudes, as wheat and barley, are still cultivated; and as the table land descends toward the north, sugar cane and other tropical plants appear, but the main ridge of the Andes still towers to great heights between these interior valleys and the Pacific coast. The highest known pass is from Lima in lat. 12° to Tarma and Pasco; it crosses the ridge at an elevation of 15,760 feet. The rain clouds swept on from the N. E. are intercepted on the eastern slopes, and the drainage is all back toward the Atlantic, whence the abundant waters have been brought by the trade winds. The strip of land 20 to 50 m. wide along the coast is singularly dry; no rains reach it from over the mountains, and the vapors raised along the Pacific are driven by the prevailing winds from its shores. The high table lands of Pasco, about lat. 11° S., are famous as the highest points of the Andes occupied by man. Here are worked some of the richest silver mines of Peru, at an elevation of 14,000 feet, and only 1,500 feet below the line of perpetual snow. From this point for 400 m. northward, to the Andes of Quito, the mountains decline in height, and no peak for more than 7° S. of the equator reaches the line of perpetual snow. The Andes crowd more closely on the coast, so that the rains that swell the sources of the Amazon fall within sight of the Pacific; yet they spread

in parallel N. and S. ridges over a vast width of country, and between the different ranges the great branches of the Amazon, as the Marañon, the Huallaga, and the Ucayali, find their way in a northerly direction to enter at right angles the main river bound on its eastern course. The valleys of these rivers afford convenient situations for roads, and they are connected with the coast by various passes over the western summits; one of the principal of these is the road from Truxillo, in lat. 8° S. on the coast, to Caxamarca in the valley of the Marañon, over a summit of 11,600 feet elevation. Thence the road continues northward to Chachapoyas, and from this place over the central ridge of the Andes to Moyobamba and Tarapoto on the Huallaga. All this fine region of the Andes, with its numerous towns and rich mines, is occupied principally by Indians. Farming and mining are almost their only employments. Except silver, products of the mountains hardly pay for transportation; the most important are the bark of the cinchona tree, which abounds in the forests on the eastern ranges, and the sarsaparilla, which is very common in the densely wooded plains of the rivers east of the mountains. North of the silver mines of Pasco, the Peruvian Andes may be said to consist of three cordilleras, known as the western, central, and eastern, of which the first is the highest, and is separated from the Pacific by an arid desert 50 m. in breadth. The summit of the Andes of Peru is the Nevado de Sasacuanca, 17,900 feet. While the snow line in Bolivia, according to Pentland, is at 17,000 feet, in Peru it descends to 15,500.—Following these ranges, we find them decreasing in altitude till they terminate in the knot of Loja, one of the lowest parts of the chain. Here begins the most magnificent series of volcanoes in the world—the Andes of Quito. Two cordilleras, running nearly due N., enclose the beautiful table land of Quito, 200 m. long by 30 wide. This table land is divided by the transverse ridges of Assuay and Tiopullo into the three basins of Cuenca, Ambato, and Quito, having the mean altitude and temperature of 7,500, 8,000, and 9,500 feet, and 62°, 61°, and 59°, respectively. The Alto de Tiopullo, or Chisinche, forms the watershed between the Pacific and Atlantic, the waters of the Quito valley flowing W. by the Esmeraldas, and those of Ambato reaching the Amazon by the Pastaza. The eastern or Royal Cordillera contains the ever-active volcano of Sangai, 17,120 feet; ruined Altár, 17,400; the perfect cone of Tunguragua, 16,579, silent since 1780; the Llanganate mountains, rich in gold; Cotopaxi, 18,862 feet—"the most beautiful and most terrible of volcanoes;" the extinct Antisana, 19,279; square-topped Cayambi, standing exactly on the equator, 19,358; and Imbabura, which in 1691 poured forth a vast quantity of mud and thousands of fishes (*pimelodes cyclopus*). In the coast range are Chimborazo, with its untrodden dome, 21,420

feet above the sea; Caraguirazo, about 18,000; Iliniza, 17,370; and Pichincha, 15,827—the only active volcano in this cordillera, and having the deepest crater on the globe. The snow limit at the equator is 15,800 feet. One degree north of the equator is the volcanic knot of Los Pastos, where the cordilleras unite, again to diverge as they enter Colombia. There the Andes spread out “like the graceful branches of the palm tree.” The coast range, la Cordillera de la Costa, divides the valley of the Cauca from the Pacific, and finally merges in the low mountains of Darien. About 120 m. N. of the equator, the other cordillera separates into two chains, of which the easternmost, Suma Paz, runs by Lake Maracaibo and terminates near Caracas on the Caribbean sea. The central chain of Quindiu divides the Cauca and Magdalena, and culminates in the volcanic Tolima, 18,270 feet, the highest peak in the new world N. of the line, and situated further from the sea (120 m.) than any other active volcano.—In general, the Andes present a steep slope toward the Pacific, and descend gradually into the vast plains of the east. In Ecuador, the western slope (according to Prof. Orton) is 225 feet per mile, and the eastern 125 feet. In Chili, says Darwin, the descent on the E. side of the cordillera is much shorter or steeper than on the Pacific side. Besides the longitudinal valleys between the cordilleras already mentioned, there are innumerable valleys of erosion on the sides of the Andes in keeping with their colossal size. The gigantic mountain chain, throughout its entire length, forms a great barrier to the interchange of life and commerce between the eastern and western sides of the continent. No river crosses it, and even the separate cordilleras are broken at few points. The passes are wild paths, narrow, steep, rugged, and often running along the edge of precipices. Man has done little to improve them, except in the elevated plains of Peru, where the incas laid out four grand roads from their favorite capital, Cuzco, which rival the similar works of the old Romans. The least elevation of these passes is rarely less than twice the height of Mount Washington. If it does not reach above the extreme limits of vegetation, it is a favorable pass. Frequently they lead through the regions of perpetual snow, and during the winter months are entirely closed. In Chili there are eight of these passes, S. of lat. 32° S., of which the chief are the Uspallata and Portillo, leading from Valparaiso to Mendoza, and reaching the altitude of 12,450 feet. There are six passes in Bolivia, of which the best is by Cochabamba leading to the Mamoré; its highest point is 15,000 feet. Peru may be crossed by three paths: from Lima to Mayro, via Cerro Pasco and Huánuco; from Lima to Tingo Maria, via Huánuco; and from Truxillo to Moyobamba, via Chachapoyas. One leading from Lima to Tarma and Pasco is 15,700 feet high, the highest pass in the Andes. Ecuador is generally crossed via the Arenal on

Climborazo, 14,250 feet, and Papallacta. The maritime chain in New Granada, though low, has but few and difficult passes. From Truxillo to Popayan a great commercial road for mules runs longitudinally along the Andes. The finest carriage ways in western South America are in the Quito valley.—There is a marked difference between the vegetation, the quadrupeds, and to some degree the birds and insects on the eastern side of the Andes and those on the western. This fact accords with geological history; for these mountains, says Darwin, have existed as a great barrier since the present races of animals have appeared; and therefore, unless we suppose the same species to have been created in two different places, we ought not to expect any closer similarity between the organic beings on the opposite sides of the Andes than on the opposite shores of the ocean. The characteristic forms of animal life on the Andes are llamas, vicuñas, alpacas, condors, and humming-birds; nearly all the domesticated animals are importations. The puma, jaguar, peccary, deer, opossum, monkey, squirrel, weasel, and a small black bear abound in the lower altitudes. The population of the Pacific states, consisting of Indians (Aymará in the southern and Quichua in the northern half) and Spanish Americans, is mainly gathered in the high valleys. Near Ocururo in Peru is the little post hut of Rumi-huasi, on a wild, forbidding height 420 feet higher than the summit of Mont Blanc—the loftiest habitation in the world.—Ascending the equatorial Andes, we find every variety of climate arranged in zones according to the altitude, and characterized by floral life. From the bananas and palms on the steaming lowlands, we pass in succession tree ferns, cinchona, *polylepis* (the last of the trees), heaths, gentians and geraniums, *peja* (the long wiry grass of the paramos), and lichens. The most prominent flowers in the Quito valley belong to the *composita*, *labiata*, *leguminosa*, and *gentianacea*. The Andes pass from the hot climates of the equatorial regions through the southern temperate zone nearly to its extreme verge. At their termination, in lat. 56° S., the climate is indeed more boisterous and wintry than that just over the limit of the frigid zone in the northern hemisphere. In the summer season, at Tierra del Fuego, the warmth is insufficient to lift the line of perpetual snow higher than 3,500 or 4,000 feet above the level of the sea, while in Norway for such a climate one must go from 11 to 14 degrees further from the equator. As the Andes toward the north spread out into broader masses, and stretch upward to higher elevations, they carry with them through the tropics the cold temperature of their southern termination. But the mountains are not only the regulators of the climate, they are also the great condensers, lifted up into the higher regions of the atmosphere to catch the abundant moisture distilled by the trade winds, and to shed it in copious streams

from the eastern slopes on which it is precipitated, eastward toward the Atlantic, feeding the great rivers of the continent, and spreading fertility along their paths.—Glaciers are rare, being found only in the narrow ravines of the southern section. The volcanoes of the Andes, 51 in number, are remarkable for their continuity, in scattered groups, from the western coast of Patagonia, in lat. 43° 28' S., to the northern limits of the Andes a few degrees from the equator; and even into Central America the continuation of this volcanic belt may be traced in the cordilleras of Costa Rica, Nicaragua, Honduras, and Mexico. The most southern group extends from Yantéles, opposite the island of Chiloe, to Coquimbo, in lat. 30°. There is then a space of more than eight degrees of latitude with no volcano known to have been in action, to which succeeds the range of volcanoes of Bolivia and Peru, the extent of which is from lat. 21° to 15° S. Thence to the volcanoes of Quito is a district of fourteen degrees of latitude, little known and thinly populated. No volcanoes are spoken of in it, but they may be there and have escaped the observation of civilized man. The volcanoes of Quito extend from 100 m. S. of the equator to 130 m. N. of it; and from their northern termination it is about six degrees further to the southern termination of the volcanoes of Central America. They are not only remarkable for the long line of country they spread over, but also for the great height of many of the peaks, and their extremely destructive character. The products of an eruption are usually water, mud, ashes, and fragments of pumice, trachyte, and porphyry. But the volcanoes of the Andes are singularly exempt from floods of lava. From high up the flanks of Antuco in Chili, the summit of which rises 16,000 feet above the sea, immense currents of lava flowed in 1828; but this is a rare occurrence, the matters usually ejected being vapors and scorie. The outbursts of the volcanoes are closely connected with the frequent and disastrous earthquakes of this region. These commotions appear to extend under the whole range of the Andes, and even far out under the ocean. So frequent are they that M. Boussingault is of opinion that a full register of them would show that they are incessant.—The geological structure of the Andes shows that the chain was slowly upheaved in mass from the sea, and has since undergone three subsidences. Indeed, there are evidences that the Andes are now subsiding again, for successive measurements indicate a lower elevation. (See "American Journal of Science," October, 1871, p. 267.) In the pass of Uspallata, the two parallel ridges, based on the ancient porphyries, are capped, the range next the coast with black clay slates containing the grypheas, ammonites, and other fossil shells of jurassic and cretaceous age, and altered by intrusion of the igneous rocks; while the eastern range is covered with still later formations, as sandstones and conglomerates made up of the

fragments of the rocks of the western range, and bearing all the appearance of the tertiary strata found along the Pacific coast. These later formations also are intermingled with trap rocks and volcanic tuffs, and altered by contact with the granitic rocks, which since the deposition of the sedimentary rocks have intruded among the strata. The metallic veins from the granite also penetrate them, and veins of gold have been worked in close proximity to fossil trunks of trees, found by Darwin standing imbedded in the stratified rocks. The Andes appear throughout their length to carry a similar geological structure, which is made manifest as well by a similarity of mineral productions as by the reports of those naturalists who have ascended the summits; granitic and porphyritic rocks form the lower portion, and on these rest immense formations of mica slate, gneiss, and quartz rock. Upon the very summits are found the tertiary strata, which, like the same formation extending along the Pacific coast, are productive in beds of bituminous coal, and the variety called brown coal, at intervals from Patagonia to Panama. Beds of this coal are worked in Chili for the use of steamships; and in the mining region of Pasco in Peru, in the immediate vicinity of its celebrated silver mines, and at an elevation of over 14,000 feet, coal probably of the same age is found in abundance. The quality of such coal is not likely to be as good as of the bituminous coals of the true coal formation, but our data are very imperfect on this point, as also whether the real carboniferous rocks are found at all in South America. The secondary rocks generally cover the granite in the mountains of Venezuela, but thin away toward the equator; and in the plains of the Rio Negro Humboldt noticed the bare granite in patches of 10,000 square yards forming the level surface. Mines of silver have frequently been alluded to in describing different localities along the Andes. Near the equator and N. of it they are not productive; but in Peru and Bolivia they are probably unsurpassed in richness by any mines of this metal in the world. The mines of cinnabar of Huanea Velica, in southern Peru, have in former times produced very large quantities of mercury, and the same ore is also found near Tarma in the valley of the Jauja river, and in the equatorial Andes, N. W. of Cuenca; platinum is met with in small grains in the alluvium near the Pacific coast of New Granada. Gold is found in the silver veins of Peru, and is worked in veins in Chili. In Bolivia it is washed from the deposits along the streams. Lead ores are common with those of silver, but are not regarded as of much value. The copper mines of Chili are very productive in the rich oxides and carbonates of this metal. Many cargoes of these valuable ores are shipped every year to Swansea in Wales to mix with the lean ores of Cornwall; and our own copper-smelting establishments along the coast receive occasional supplies from the same

source. The production of Chili, and of Peru also, in these ores might be largely increased, were there better facilities for getting the ores to the coast, or were there convenient supplies of fuel for converting them into products more economical for shipment. The nitrate of soda mines of Peru have already been noticed. The finest gem of the Andes is the emerald, the Tunca mines near Bogotá furnishing nearly all in the market.—The name Andes, according to Garcilasso, is derived from *Anti*, the name of an ancient province E. of Cuzco. Others think it may have come from the aboriginal word *anta*, copper, this metal being so abundantly distributed through the mountains. Col. Tod, in his work on Rajasthan, notices that the northern Hindoos apply the name Andes to the Himalaya mountains. But Humboldt says there are no means of interpreting it by connecting it with any signification or idea; if such connection exist, it is buried in the obscurity of the past.—See “The Narrative of the Ten Years’ Voyage of H. M. Ships Adventure and Beagle,” by Captain King, Captain Fitzroy, and Charles Darwin (London, 1839); Darwin’s “Geological Observations on South America” (London, 1846); “The U. S. Naval Astronomical Expedition to the Southern Hemisphere during the years 1849, ’50, ’51, ’52,” by Lieut. J. M. Gilliss and others (Philadelphia, 1856), especially vol. ii., on “The Andes—Minerals, Animals, Plants, and Fossils;” and “The Andes and the Amazon,” by J. Orton (New York, 1870).

ANDLAW, Franz Xaver von, a German diplomatist, born at Freiburg, Baden, Oct. 6, 1799. He served in the foreign office and diplomatic service of Baden, and was for many years ambassador at Vienna retiring in 1856. He wrote *Erinnerungsblätter aus den Papieren eines Diplomaten* (Frankfort, 1857), and *Mein Tagebuch*, embracing the years 1811–’61 (2 vols., Frankfort, 1862). Among his other principal works is *Die Frauen in der Geschichte* (2 vols., Mentz, 1861).

ANDOCIDES, an Athenian orator, born in 467 B. C. Accused in 415 of aiding Alcibiades in profaning the mysteries and mutilating the Herms, he was banished after revealing the names of four of the guilty parties, who were then executed. On the establishment in 411 of the government of the 400, he returned to Athens, but was imprisoned on a charge of rendering some service to their democratical opponents at Samos. Escaping soon after, he fled to Cyprus, where he remained till another revolution at Athens encouraged him to go thither once more to solicit the restoration of his rights. He was unsuccessful, and had to retire a third time into banishment. On the overthrow of the tyranny of the thirty in 403 he was, however, permitted to return, and for several years he enjoyed much of his former consideration and influence; but having been convicted of illegal conduct during an embassy to Sparta, he was a fourth time driven into ex-

ile, where he died at an advanced age. There are three orations of Andocides extant in defence of himself, besides one against Alcibiades, which is, however, considered spurious. His style is simple and unadorned. The best edition of these orations is that of Baiter and Sauppe (Zürich, 1838).

ANDORRA, a small republic situated between the French town of Foix, in the department of Ariège, and the Spanish town of Urgel, in the province of Lerida, in valleys shut in on all sides by the Pyrenees, excepting on the south along the Balira and its affluents; area, 200 sq. m.; pop. estimated at about 12,000. It is divided into 6 communes. The capital, of the same name, is in lat. 42° 30’ N., lon. 1° 30’ E., 30 m. S. of Foix and 12 m. N. of Urgel; pop. about 800. The other principal places are Ordino, San Julian, Encam, Canillo, Masana, and the beautifully situated springs of Escaldas, which French speculators have sought to convert into a fashionable watering and gambling place. The chief products are tobacco, grapes, and timber. Game abounds. Cereals are imported from France. There is some traffic in wood, iron, and wool, but the principal occupation is cattle raising.—The Andorrans, having assisted Charlemagne against the Moors, were rewarded with the privilege of self-government, the emperor only reserving to his crown some feudal claims, which were ceded in 819 by Louis le Débonnaire to the bishop of Urgel. The counts of Foix and subsequently Henry IV. reasserted these claims, but they were relinquished during the French revolution, and partly restored in 1806 at the request of the people of Andorra. The republic continues to maintain its independence under the suzerainty of France and the authority of the bishop of Urgel. The executive power is held by the president or first syndic of the general council, assisted by a second syndic, both elected for four years by its 24 members, who are themselves elected for the same term by four heads of families of each commune. Justice is administered by two vigneriers or primary magistrates, respectively appointed by the French government and by the bishop of Urgel, who also alternately name a civil magistrate. The republic pays a biennial tribute of 960 francs to France and one of 891 francs in the intervening years to the bishop of Urgel. The Andorrans are a fine, vigorous race, who boast of their poverty as preserving their freedom, and are very proud of their ancient institutions. Every man from 16 to 60 is trained as a soldier. They are illiterate, and so incommunicative that in Catalonia to assume ignorance is called to play the Andorran. They are, however, kindly and hospitable, marry chiefly among themselves, and the principal families are all related to each other. They speak a Catalonian dialect. The bishop of Urgel is the sole dispenser of ecclesiastical patronage for four months, his appointments being subject to papal ratification during the rest of the year.—

See Baquer's *Historia de la república de Andorra* (Barcelona, 1849); Ziegler's *Reise in Spanien* (Leipsic, 1852); and Bayard Taylor's "By-Ways of Europe" (New York, 1869).

ANDOVER, a market town of Hampshire, England, 20 m. N. of Southampton; pop. in 1871, 5,501. Its name is derived from the Anglo-Saxon *Andefaran* (ferry over the river Ande). Andover has a large malt trade and an extensive traffic in timber with Portsmouth. The fair which is annually held at Weyhill near Andover was formerly one of the most celebrated in Europe.

ANDOVER, a town of Essex county, Mass., on the Merrinack and Shawshen rivers, 21 m. N. of Boston; pop. in 1870, 4,873. The village is pleasantly situated in an elevated and healthy district, and has railroad connection with Boston, Lawrence, Lowell, Salem, and Newburyport. The chief importance of the town is derived from its literary institutions. It is the seat of Phillips academy, founded in 1780 by the munificence of John and Samuel Phillips, who were sons of a clergyman of Andover and graduates of Harvard college. The former was prominent in the politics of New Hampshire, and the latter was lieutenant governor of Massachusetts. Its funds are large, and it has a complete chemical and philosophical apparatus, and libraries containing 2,500 volumes. There are 8 instructors, and 154 students in the classical and 74 in the English department. The Andover theological seminary, an offshoot of Phillips academy and under the same trustees, was founded in 1807, with the object of "providing for the church a learned, orthodox, and pious ministry." Its early donors were Samuel Abbot, a merchant of Boston, Moses Brown and William Bartlett, merchants of Newburyport, and John and Phœbe Phillips of Andover. The whole amount it has received is not less than \$400,000. It is under the control of the Congregationalists, but is open to Protestants of all denominations. It has 5 professors, generally more than 100 students, and a library of 30,000 volumes. In 1870 the number of graduates was 1,618. Its course of studies occupies three years. Tuition and room rent are free to all, and additional aid is given to a portion of the students. The "Bibliotheca Sacra," a leading organ of New England theology, edited by the professors, is published as a quarterly at Andover. The Abbot female academy, established here in 1829, is a flourishing institution, designed especially for the education of female teachers. The buildings of these institutions are of brick, and stand near together on an eminence commanding a fine prospect. There are generally from 400 to 500 students in all the institutions. Andover contains also a bank and 8 churches, 5 of which are Congregational, 1 Episcopal, 1 Methodist, and 1 Baptist. In 1865 there were 4 factories for the manufacture of tow and flax, employing 100 males and 150 females; 5 woolen mills, with 24 sets of machinery, employing

212 males and 188 females; a file factory with 350 hands; and an establishment for the manufacture of steel, employing 100 hands.

ANDRADA, Antonio d', a Portuguese missionary, born about 1580, died in Goa, Aug. 20, 1633. He entered the society of Jesus at Coimbra in 1596, joined the East Indian mission, arrived at Goa in 1600, and was appointed superior of one of the houses of the society. Hearing that vestiges of Christianity existed in Thibet, he set out, disguised as a Mongolian, to visit that country in 1601, and reached Caparanga, the military capital, where it is said he built a church in honor of the Virgin. He made a second journey to Thibet in 1625-'6, and was again most favorably received. Returning to the Portuguese settlement, he was appointed provincial of Goa and deputy of the inquisition. His *Novo descobrimento do Grão Catayo, ou dos Reynos de Tibet* (Lisbon, 1626), was translated into Italian, and from that language into French (new ed., 1795).

ANDRADA E SYLVA, Benifacio José d', a Brazilian statesman and naturalist, born in Santos, June 13, 1765, died near Rio de Janeiro, April 6, 1838. Under the patronage of the Lisbon royal academy he was enabled to travel in Europe, studying in Paris under Lavoisier, at the mining school of Freiberg under Werner, and at Pavia under Volta. In 1800 he became professor of metallurgy and geognosy at Coimbra, and soon afterward general intendant of the Portuguese mines. He took an active part in the construction of canals and public works, and in 1812 he was named perpetual secretary of the Lisbon academy of sciences. He returned to Brazil in 1819, and became one of the champions of national independence. As vice president of the provincial junta (Dec. 24, 1821) he urged Dom Pedro I. to remain in Brazil, became his minister of the interior (Jan. 16, 1822), was removed from his office Oct. 25, but reinstated Oct. 30, at the request of the people, and was finally displaced July 17, 1823, on account of his liberalism. In the constituent assembly his opposition became so bitter that after its dissolution (Nov. 12, 1823) he was arrested and banished to France, and lived in Bordeaux till 1829, when he was permitted to return to Brazil. Dom Pedro I. abdicating April 7, 1831, in favor of Dom Pedro II., selected Andrada as the latter's guardian and tutor. In 1833 he was tried on a charge of intriguing for the restoration of Dom Pedro I. Although acquitted, he was deprived of his position and restrained of his liberty. He wrote on mineralogy, and is the author of *Poesias d'America Elysea* (Bordeaux, 1825).—His brothers, ANTONIO CARLO and MARTIM FRANCISCO D'ANDRADA, were associated with Brazilian politics and shared his fate. The latter (born in Santos in 1776, died there Feb. 23, 1844) left two sons: JOSÉ BONIFACIO, author of *Rosas e goivros* (São Paulo, 1849); and MARTIM FRANCISCO, author of *Lagrimas e sorrisos* (Rio, 1847), and of the drama *Januario Garcia* (1849).

ANDRAL, Gabriel, a French physician, born in Paris, Nov. 6, 1797. His father, Guillaume, was a member of the academy and chief physician to the French army in Italy and to Murat, and afterward to Louis XVIII. Through the influence of his father-in-law, Royer-Collard, and also by his fame as the author of the *Clinique médicale* (4 vols. 8vo, 1824-'6), he was appointed in 1827 professor of hygiene in the faculty of Paris, and in 1830 was promoted to the chair of internal pathology. In 1839 he succeeded Broussais as professor of pathology and general therapeutics. In conjunction with Gavarret and Delafond he published researches *Sur les modifications de proportion de quelques principes du sang*. His *Précis d'anatomie pathologique* (3 vols., Paris, 1829), *Cours de pathologie interne* (3 vols., 1836), and *Essai d'hématologie pathologique* (1843) have been translated into foreign languages.

ANDRÁSSY, Gyula (Julius), count, a Hungarian statesman, born in the county of Zemplén, March 8, 1823. His ancestors were known from the 11th century in Bosnia, and from the 16th in Hungary, where they acquired vast estates with the rank of count. The Italian branch of the same stock, the margraves d'Andrássy and chevaliers de Rivalto, have been extinct since 1793. The head of the senior Hungarian branch, Count CHARLES, the father of Count Julius (born in Gömör in 1792, died in Brussels in 1845), was an opposition member of the diets of 1839-'40 and 1843-'4, and wrote in German "Outlines of a Possible Reform in Hungary." Count Julius was a member of the Presburg diet of 1847-'8, lord lieutenant of the county of Zemplén, led the militia against the Austrians, went as Hungarian ambassador to Constantinople, and from 1849 to 1857 was an exile in France and England. He was a member of the diet of 1861, vice president of the diet of 1865-'6, and chairman of the committee on "the common relations of the Austrian empire." After the accession of the Beust ministry, Oct. 30, 1866, and the recognition of Hungarian sovereignty under a dual Austro-Hungarian empire, Count Andrassy was, at Deák's demand, appointed Hungarian prime minister of the empire, Feb. 17, 1867. He also acted as minister for the national defence, popularized his administration by selecting several of its members from outside the ranks of the aristocracy, carried out the measures broached by the committee of 1865-'6, under the guidance of Deák, in support of the sovereign rights of Hungary, and instituted various financial, military, and judicial reforms. Sympathizing with France during the Franco-German war, he yet insisted upon neutrality. He approved the overthrow of the papal temporal power, and was rather antagonistic to Russia in the eastern question, until he succeeded Count Beust (Nov. 9, 1871) as foreign minister of the Austro-Hungarian empire, when he seemed disposed to eschew all external complications, and bent on the preservation of peace.

ANDRÉ, Johann Anton, a German composer, born at Offenbach, near Frankfort-on-the-Main, Oct. 6, 1775, died there, April 5, 1842. His father was Johann André, founder of the celebrated musical establishment, which still continues to prosper at Offenbach, and which under his son's direction attained a high degree of celebrity, especially by his purchase of the compositions left by Mozart. His own compositions comprised over 100 pieces of all sorts of music, and at the time of their publication were popular in southern Germany, although they are at present almost forgotten. He wrote a *Lehrbuch der Tonkunst* (Offenbach, 2 vols., 1832-'43, the last part by his pupil Heinrich Henkel), and published Mozart's diary, and some original pieces of that composer.

ANDRÉ, John, a British officer, born in London in 1751, executed at Tappan, Rockland co., N. Y., Oct. 2, 1780. At 18 years of age he embarked in a mercantile career, but being disappointed in a love affair he entered the army, and in the autumn of 1775 was taken prisoner by Gen. Montgomery in Canada. He afterward became aide-de-camp successively to Gen. Grey and Sir Henry Clinton, the latter of whom in 1779 caused him to be promoted to the rank of major, and appointed adjutant general of the British army in North America. In this capacity he soon became engaged in a secret correspondence with Gen. Benedict Arnold of the continental army, the object of which was the betrayal of the American cause to the British commander-in-chief. Early in August, 1780, Arnold assumed command of West Point on the Hudson river, then the strongest and most important post in the United States, and considered the key of communication between the eastern and southern states. In furtherance of his treasonable designs he proposed to Clinton, whose headquarters were then in New York, to deliver this fortress into his hands, and with a view of perfecting arrangements for that purpose demanded a personal interview with André. The latter accordingly repaired on Sept. 20 to Dobbs Ferry, on the Hudson, and failing to meet Arnold there, went on board the British sloop-of-war *Vulture*, which was anchored in the river near that place. On the night of the 21st he went ashore at a point about 6 m. S. of Stony Point and had an interview with Arnold, which was prolonged into the morning of the 22d. On departing for West Point Arnold gave him a passport, authorizing John Anderson (the name assumed by André) to pass the American lines to White Plains or below, if he chose; and also six papers in his own handwriting which would enable the British general to direct his attacks against West Point with almost absolute certainty of success. These, at Arnold's suggestion, André concealed between the soles of his feet and his stockings. André had fully expected to return to New York on board the *Vulture*; but finding this impossible, he reluctantly crossed the river to Verplanck's

Point, accompanied by one Joshua Smith, at whose house the interview with Arnold had taken place, and prepared to journey on horseback to New York. Previous to this he had, contrary to the positive instructions of Clinton, exchanged his uniform of a British officer for a disguise. He passed the night of the 22d with Smith at a place called Miller's, and early on the succeeding morning was again in the saddle. Near Pine's bridge Smith left him, and he proceeded on his way alone, taking the Tarrytown road through what was then known as the "neutral ground," a region devastated by marauding parties from both armies. Between 11 and 12 o'clock, when within half a mile of Tarrytown, he was challenged by three men, John Paulding, David Williams, and Isaac Van Wart, to whom he incautiously replied that he belonged to the "lower" or British party. His captors, who were Americans, immediately searched his person and discovered the treasonable papers. Rejecting his offers of pecuniary reward, they conveyed him to the nearest military station at North Castle. He was thence taken to Tappan, the headquarters of the American army, and tried as a spy before a board of officers consisting of six major generals and eight brigadiers, by whom he was found guilty and sentenced to death. Every effort was made by Clinton to save him, and every fair opportunity allowed by Washington, but his offence under military law was unpardonable. His request that he might be shot could not under the circumstances be granted, and he was hanged as a spy, in the full uniform of a British officer, and in the presence of a large detachment of troops and an immense concourse of people, whom he bade witness that he died like a brave man. During the brief period of his captivity he endeared himself to all who came in contact with him by his sweetness of disposition and the charm of his conversation and manners. His fate was lamented not less sincerely by American officers than by his own countrymen. Its justice, notwithstanding the exasperation which it originally provoked in England, is now generally conceded. In 1821 André's remains were removed to England, and are now interred in Westminster Abbey beneath a costly monument of marble.

ANDREA, Girolamo d', a Roman cardinal, born in Naples, April 12, 1812, died in Rome, May 15, 1868. He was a member of an old patrician family, and was intrusted by Pius IX. with important diplomatic and ecclesiastical functions. For some time he displayed great zeal in behalf of the papal government, and was made cardinal in 1852. Subsequently he became hostile to the Roman see and showed a leaning toward the party of Italian unity. He was at first treated with forbearance, but in 1865 an investigation was ordered into his conduct, and he was removed from his bishopric of Sabina, and in 1867 ordered to leave Naples, where he was then residing, and present himself at Rome.

After some hesitation he obeyed, and was subjected to certain ecclesiastical penalties, without being permanently deprived of his dignities. He did not long survive his disgrace, and died very suddenly.

ANDREA PISANO, an Italian sculptor and architect, born in Pisa in 1270, died in Florence in 1345. He was one of the first to depart from the Gothic style in art. After having been employed at the cathedral of Pisa, in the execution of the bronzes at Perugia, and of some small figures in marble for Santa Maria al Ponte at Pisa, he was invited to assist in completing the façade of the cathedral of Santa Maria del Fiore of Florence. He also executed a marble statue of Boniface VIII., and statues of St. Peter and St. Paul, for the same church, which were much admired. After having spent some time at Venice, where he made several small statues for the front of St. Mark's, he returned to Florence, and after the death of Arnolfo di Lapo was placed in charge of all the public works. He executed the bronze reliefs for the gates of the baptistery, which gained for him great fame and the honorary citizenship of the republic. The subject is the life of St. John, and the incidents are represented in 22 compartments. He designed the castle of Scarperia, the arsenal of Venice, and the church of San Giovanni at Pistoia. By order of the adventurer called the duke of Athens, who in 1342 made himself by a *coup-d'état* master of Florence, he fortified and enlarged the ducal palace, ornamented the city wall with towers and magnificent gates, and designed a small citadel.

ANDREA DEL SARTO. See **SARTO**.

ANDRÆ. I. Jakob, a German theologian, born at Waiblingen in Würtemberg, March 25, 1528, died June 7, 1590. He studied at Stuttgart and Tübingen, and was ordained a pastor in the former town in 1549. In 1557 he became preacher to the court of Duke Christopher of Würtemberg, whom he accompanied to the diets of Ratisbon and Frankfort. In 1562 he was appointed professor of theology and chancellor of the university at Tübingen, and provost of the church of St. George, and from this time took an important part in the movements and discussions of the Protestant church. He was particularly influential in securing the adoption of the *Formula Concordiæ* as the common profession of faith of the two Protestant parties. **II. Johann Valentin**, a voluminous German author, grandson of the preceding, born at Herrenberg, Aug. 17, 1586, died in Stuttgart, June 27, 1654. After travelling over Germany, Switzerland, Italy, and France, he filled various ecclesiastical positions, and for some time officiated at the chapel of the duke of Würtemberg. His *Mythologia Christiana* and some of his other Latin works, have been partly translated into German by Herder and Sonntag; and his *Civis Christianus, sive Peregrini quondam errantis Restitutions* (Strasburg, 1619), was translated into French under the title of

Le sage Citoyen (Geneva, 1622). He published in 1633 a work advocating republican Christianity in Germany. His German writings include several poems; among others, *Christlich Gemäl* (Tübingen, 1612), which is highly praised by Herder, who declares that Andrea boldly announced truths in the 17th century which no one would dare to express in the 18th. He first made known the order of Rosicrucians in two or three publications, and is regarded by some as its founder or inventor; but this is denied by Herder. (See ROSICRUCIANS.) His autobiography, in Latin, was published at Berlin in 1849.

ANDREÆ, Laurentius, or Lars Andersson, a Swedish scholar, born in 1482, died at Strengnäs, April 29, 1552. He studied in Rome, and upon his return to Sweden was appointed archdeacon of the cathedral at Upsal. Gustavus Vasa made him his chancellor, and requested him to undertake the translation of the New Testament. In 1540 he was accused of having concealed his knowledge of a conspiracy against the life of the king, and was condemned to death, but finally escaped by the payment of heavy fines. From that time he lived retired in Strengnäs. His translation of the New Testament, which was the first version in Swedish, was published in folio in 1526.

ANDREANI, Andrea, an Italian painter and engraver, surnamed Il Mantuano, born in Mantua about 1540, died in Rome in 1623. He devoted himself principally to wood engraving, and exerted a marked influence upon the development of that branch of art. His cuts are often in chiaroscuro, and his works have often been confounded with those of Altdorfer, from his using a similar monogram. Two of his best prints are after Titian's "Deluge" and "Pharaoh's Host destroyed in the Red sea."

ANDREANOV ISLANDS. See ALEUTIAN ISLANDS.

ANDREÆ, Karl Theodor, a German geographer, born in Brunswick, Oct. 20, 1808. His studies at Jena were interrupted by his trial (1838) for revolutionary proceedings, and being acquitted, he thenceforward connected himself with journalism. Since 1861 he has been editor of the *Globus*, a geographical and ethnographical publication at Hildburghausen. His works, chiefly relating to the American continent, include, besides his copious contributions to the Brunswick periodical *Westland* (5 vols., 1851-'83), *Nordamerika in geographischen und geschichtlichen Umrissen* (2d ed., Brunswick, 1854); *Buenos Ayres und die argentinische Republik* (Leipsic, 1856); *Geographische Wanderungen* (2 vols., Dresden, 1859); and *Abschmitten* (1871). He is also the author of *Forstungsreisen in Arabien und Ostafrika* (2 vols., Leipsic, 1860-'61); and of *Geographie des Welt Handels* (vol. i., Stuttgart, 1863).

ANDREANI, A. Francesco, an Italian comedian of the 16th and 17th centuries, chief of the celebrated troupe called *I Gelosi*. He published *Le bravure del capitano Spavento* (Venice,

1609), *Ragionamenti fantastici* (1612), and two theatrical pieces in verse (1611). **II.**

Isabella, wife of the preceding, a comic actress and an author, born in Padua in 1562, died in Lyons in 1604. She acquired great fame not only by her acting both in Italy and France, but by her varied accomplishments and learning, and her irrefragable character. Medals were struck in her honor with the legend, *Æterna fama*. Her writings both in prose and verse are numerous, nearly all relating to love.

III. Giovanni Battista, son of the preceding, a comedian and poet, born in Florence in 1578, died in Paris about 1650. Besides three long and several shorter poems, he was the author of 18 dramas, from one of which, a "sacred representation" entitled *Adamo*, Milton has been supposed to have borrowed the plot of "Paradise Lost." There is, however, little resemblance between the two works.

ANDREÒSSI, Antoine François, count d', a French general and savant, born at Castelnaudary, March 6, 1761, died at Montauban, Sept. 10, 1828. He entered the artillery at an early age, and served under Bonaparte in Italy and in Egypt, where he took an active part in the work of the scientific commission. He was one of the few selected by Bonaparte to accompany him on his return to France, aided him powerfully in seizing the government, and was made inspector general of artillery and engineering. After the treaty of Amiens he was ambassador to London in 1809, governor of Vienna, and afterward ambassador to Constantinople till the restoration. He again engaged in politics during the Hundred Days (1815), was one of the commissioners to treat with the foreign armies after the battle of Waterloo, and thenceforth devoted himself to scientific pursuits. He made important contributions to the *Mémoires sur l'Égypte*.

ANDRÉS, Juan, a Spanish scholar, born of a noble family at Planes in Valencia, Feb. 15, 1740, died in Rome, Jan. 17, 1817. He early entered the society of the Jesuits, and on their expulsion from Spain in 1767 was removed with his companions first to Corsica, and then to Ferrara, where he taught philosophy; but the Jesuit college there was soon suppressed by the pope, and he afterward resided chiefly at Mantua and Parma. In 1776 he published in Italian *Saggio della filosofia di Galileo*, expounding with fairness the system of that philosopher. His principal work is *Dell' origine, de' progressi e dello stato attuale d'ogni letteratura* (7 vols. 4to, Parma, 1782-'99; 4th ed., 23 vols. 8vo, Pisa, 1821). He became blind in 1815 and retired to Rome, but continued his scientific and literary pursuits till his death.

ANDREW, a N. W. county of Missouri, separated from Kansas by the Missouri river, and intersected by the Platte and several other streams; area, 425 sq. m.; pop. in 1870, 15,137, of whom 401 were colored. It has railroad communication with St. Joseph. The soil is fertile, and well adapted to grain, tobacco,

hemp, and pasturage. In 1870 the county produced 107,325 bushels of wheat, 1,086,375 of corn, 178,332 of oats, 102,967 of potatoes, 187,663 lbs. of butter, 31,825 of wool, and 5,941 of tobacco; value of animals slaughtered, \$463,582. Capital, Savannah.

ANDREW, the name of three Hungarian kings of the family of Árpád, the founder of the Magyar monarchy.—**Andrew I.**, a cousin of St. Stephen, who introduced Christianity among his subjects, and successor of Aba Samuel. In 1046, in order to win partisans to his claims to the crown, he allowed a persecution of the Christians. He warred more or less successfully against Henry III., emperor of Germany, against his own brother Bela, supported by Boleslas II., king of Poland, was defeated by the Poles and the Hungarian malcontents, and died soon after, in 1061.—**Andrew II.**, called the Hierosolymitan, ascended the throne in 1205, in a civil war against his own nephew, Ladislas III., and died after a checkered reign of 30 years. (See HUNGARY.)—His third wife was Beatrice d'Este, who returned to Italy, and gave birth there to a posthumous son named Stephen, who married a rich Venetian lady, Tomasina Morosini, the mother of **Andrew III.**, called the Venetian. He succeeded Ladislas IV. in 1290, and was obliged to defend his crown against the pretensions of Pope Nicholas IV. and the emperor Rudolph of Hapsburg, both of whom claimed it as their special fief, as well as against Charles Martel, the son of the king of Naples, who was by his mother a descendant of the house of Árpád. Andrew was victorious, but the dissatisfied magnates raised up a new pretender in the person of Charles Robert, son of Martel; and Andrew died in 1301, disgusted and mortified by the rebellion. With him the lineage of Árpád ended.

ANDREW, *Saint*, one of the twelve apostles, born at Bethsaida. The name of his father was Jonas. He was a disciple of John the Baptist, and the first called of the disciples of Jesus Christ, to whom he brought his brother Simon, afterward called Peter, and is hence called by some of the fathers "the rock before the rock." Of his apostolic labors nothing is said in the Acts of the Apostles. According to Origen, he preached in Scythia. St. Jerome says that he preached also in Achaia, and other ancient writers say also in Sogdiana, Colchis, Argos, and Epirus. He is the principal patron of Scotland. Tradition reports that he was crucified at Patræ, now Patras, in Achaia, on a cross of this form, \times (*crux decussata*), hence called St. Andrew's cross.

ANDREW, *James Osgood*, D. D., an American clergyman, one of the bishops of the Methodist Episcopal church South, born in Wilkes county, Ga., May 3, 1794, died in Mobile, Ala., March 2, 1871. At the age of 18 he was licensed to preach, and in December, 1812, he was received into the South Carolina conference. At the general conference of 1832 he was elected bishop of the Methodist Episcopal church. His sec-

ond wife being the owner of slaves, the northern delegates to the general conference of 1844 judged that "this would greatly embarrass the exercise of his office as an itinerant general superintendent, if not in some places entirely prevent it." Accordingly, the majority of the body resolved "that it is the sense of this general conference that he should desist from the exercise of this office so long as this impediment remains." The southern delegates, considering this a virtual suspension from the episcopal office, and therefore extra-judicial and unconstitutional, entered their protest. The result was an amicable division of the church into two independent jurisdictions, with an equitable apportionment of the church property. The southern division, under the name of the Methodist Episcopal church South, held a general conference at Petersburg, Va., in May, 1846, at which time Bishop Soule, senior bishop of the M. E. church, and Bishop Andrew gave in their adherence to the church South. Bishop Andrew continued to exercise his episcopal functions till 1868, when he retired from active duty on account of age. His volumes of "Miscellanies" and on "Family Government" have been widely circulated.

ANDREW, *John Albion*, 21st governor of Massachusetts since the adoption of the constitution of 1780, born in Windham, Me., May 31, 1818, died in Boston, Mass., Oct. 30, 1867. He graduated at Bowdoin college, Me., in 1837, and immediately afterward commenced the study of law in Boston, where in 1840 he was admitted to the bar. During the next 20 years he practised his profession in that city, his most conspicuous efforts being called forth by causes arising under the fugitive slave law of 1850; and in 1858, having during the previous ten years been closely identified with the anti-slavery party of Massachusetts, he was elected a member of the state legislature from Boston. In 1860 he was a member of the republican convention which nominated Mr. Lincoln for the presidency, and in the same year was elected governor of Massachusetts by the largest popular vote ever cast for any candidate. Anticipating the conflict between the government and the seceding states, he early took measures to place the militia of Massachusetts on a footing of efficiency; and within a week after the president's proclamation of April 15, 1861, he despatched five regiments of infantry, a battalion of riflemen, and a battery of artillery to the assistance of the government. He subsequently took an active part in raising and equipping the Massachusetts contingent of three years' volunteers. He was reelected governor of Massachusetts in 1861, and made frequent visits to Washington and other places to confer with public men on national affairs. He took part in the conference held by the governors of the loyal states at Altoona, Penn., in September, 1862, and prepared the address which they subsequently presented to the president. He presided at the first national Unita-

rian convention in 1865. He retired from the office of governor in January, 1866, having positively declined a fifth reelection, and resumed the practice of the law. He afterward also declined an offer of the presidency of Antioch college, Ohio.

ANDREWS, James Pettit, an English historian, born near Newbury, Berkshire, in 1737, died in London, Aug. 6, 1797. His most important work (which he did not live to complete) was his "History of Great Britain, connected with the Chronology of Europe." The part published commences with Caesar's invasion and ends with the accession of Edward VI. The plan of the work is peculiar, a portion of the history of England occupying one page, while the synchronous portion of the history of Europe is placed on the page opposite. He also wrote a continuation of Henry's "History of Britain" to the accession of James I. (1796), and an amusing collection of "Anecdotes" (1789).

ANDREWS, Lancelot, an English scholar and prelate, born in London in 1555, died in Winchester house, Sept. 25, 1626. He was a favorite of James I., who made him his lord almoner, and successively bishop of Chichester, Ely, and Winchester, and a privy councillor; and he was one of the authors of King James's translation of the Scriptures. His *Tortura Torti*, a large 4to volume (1609), was an answer to Bellarmine's attack upon James's "Defence of the Right of Kings." His other principal works are his "XCVI Sermons," "Lectures on the Ten Commandments," and "Posthumous and Orphan Lectures," all published after his death. His *Præces Privata* (1674) is a collection of passages from the Bible and the fathers in Greek and Latin, still much used in the English translation ("Manual of Private Devotions and Meditations for Every Day in the Year"). His style, though much admired in his own day, is quaint, affected, and overloaded with imagery. He had high notions of ecclesiastical authority, which brought him into conflict with the puritans. He was generally esteemed, however, as a pious, charitable, upright, and munificent prelate.

ANDRIA, a town of S. Italy, in the Neapolitan province of Bari, situated in a fine plain, 32 m. W. N. W. of Bari; pop. in 1871, 34,084. It has a royal college, a small Gothic palace, and a superb cathedral. The favorite hunting seat of Frederick II., Castel del Monte, about 12 m. from the town, is still an imposing structure. In 1799 Andria was nearly destroyed by the bombardment of the French, after a gallant defence.

ANDRIEUX, François Guillaume Jean Stanislas, a French author, born in Strasburg, May 6, 1759, died in Paris, May 10, 1833. He studied law, and distinguished himself as the advocate of the Abbé Mulot in the affair of the diamond necklace. He welcomed the revolution with enthusiasm, but on the fall of the Girondists was obliged to hide himself. On May 23, 1794, he returned to Paris and began to study Eng-

lish literature, and several of his pieces from this time show traces of his familiarity with Swift, Addison, and Steele. In 1795 he was made judge of the court of cassation, was admitted into the newly organized national institute, and was awarded a pension of 2,000 francs by the convention. In April, 1798, he was chosen by the moderate party one of their candidates to the council of 500. After the 18th Brumaire he was appointed by the consulate a member, and afterward secretary and president of the tribunate; but the first consul removed him in September, 1802. After having declined the office of censor, offered to him by Fouché, with 8,000 francs salary, he accepted that of librarian to Joseph Bonaparte, with 6,000 francs, a post which he held for ten years. In 1802 he wrote for the théâtre Louvois, of which his friend Picard was the director, *Helvétius, ou la vengeance d'un sage*. After the death of this philosopher, he was one of the habitués of the famous *salon* of Madame Helvétius at Auteuil. In 1814 he was elevated to the professorship of French literature in the college of France. The romantic school of literature was the object of his unsparing attacks. He was one of the founders of the *Décades philosophiques et littéraires* (1794-1807). Among his more remarkable contributions to the French stage are *Les Étourdis*, performed with brilliant success in 1787; *Le trésor* (1804); *Molière avec ses amis* (1804); *La comédienne* (1816); and his tragedy of *Brutus* (1830). His complete works were published in 4 vols., 1817-'23, and in 6 vols., 1828.

ANDRISCUS, or **Pseudo Philip**, a native of Adramyttium, of humble origin, who in 154 B. C. assumed the name of Philip, proclaiming himself the natural son of Persens, the last king of Macedon, whom he strikingly resembled. He applied for help to Demetrius Soter, brother-in-law of Persens, who delivered him to the Romans. Escaping from Rome to Thrace, he raised an army, and drove the Romans out of Macedonia and Thessaly (149), but was checked at Thermopylæ and driven back by Scipio Nasica. He soon afterward defeated and slew the Roman prætor Juventius, took the title of king of Macedon, and formed an alliance with Carthage. In 148 he was twice defeated by Q. Cæcilius Metellus (who was hence surnamed Macedonicus), fled to the Thracian king Byzas, was by him delivered to the Romans, and, after granting the triumph of Metellus at Rome, was executed by order of the senate in 146.

ANDROCLUS, a Roman slave of the early part of the first century, of whom Aulus Gellius says that having fled from the tyranny of his master and been recaptured, he was sentenced to be devoured by wild beasts in the circus; but a lion which had been let loose upon him recognized him as a man who had once relieved it of a thorn in its foot, and immediately began to caress him. The emperor ordered Androclus to be pardoned, and presented

with the lion, which he used afterward to lead about Rome.

ANDROIDES. See **ATTOMATON**.

ANDROMACHE, the daughter of Eëtion, king of Cilician Thebe and wife of Hector, by whom she had a son named Scamandrius or Astyanax. She lost her father and her seven brothers at the capture of Thebe, her husband in the defence of Troy, and her son on the fall of the latter city, when she became the prize of Pyrrhus, the son of Achilles, to whom she bore three sons, Molossus, Pielius, and Pergamus. On the death of Pyrrhus she became the wife of Helenus, brother of Hector and ruler of Chaonia, a part of Epirus, by whom she had a son called Cestrinus.

ANDROMEDA, a mythical princess, daughter of Cepheus the Ethiopian king and Cassiopea. Her mother having boasted that the beauty of her daughter surpassed that of the nereids, the latter prevailed on Neptune to afflict the country with a deluge and a sea monster. The oracle of Ammon promised that if Andromeda was surrendered to the monster, Ethiopia should be released. The princess was chained to a rock by the shore, and rescued by Perseus, who slew the monster and married Andromeda. Phineus, to whom she had previously been promised, attempted during the celebration of the nuptials to slay Perseus and carry off the bride, but was himself killed with all his associates. After her death, Andromeda was translated to the firmament and placed among the stars.

ANDRONICUS, the name of four emperors of Constantinople.—**Andronicus I. Comnenus**, grandson of Alexis I., born in 1110, died Sept. 12, 1185. He distinguished himself by his martial ability, dissolute conduct, and romantic adventures. In his youth he served against the Turks, was for some time a prisoner, and was afterward appointed to the military command of Cilicia. He besieged Mopsuestia, and though his campaign was unsuccessful, he was rewarded by his cousin the emperor Manuel with new honors. He engaged in a treasonable correspondence with the king of Hungary, and was imprisoned twelve years in a tower of the palace. Escaping after two unsuccessful attempts, he reached Kiev in Russia, persuaded the grand duke Yaroslav to form an alliance with Manuel against the Hungarians, and for this was pardoned, but was afterward exiled to a command on the Cilician frontier. At the head of a band of adventurers, he undertook the pilgrimage to Jerusalem, and, after roving lawlessly through Persia and Turkey, at length fixed his residence at Enoë, a city of Pontus. On the death of Manuel the populace called him to the purple. He put to death the son and widow of Manuel (1183), but was strict in dispensing justice among the people. A popular rising in favor of his kinsman Isaac Angelus put an end to his career, and he was murdered by the populace with slow tortures.—**Andronicus II. Palæologus**, the Elder, born in 1258, died Feb.

13, 1332. He was crowned emperor in his 15th year, and held the title nine years as the colleague, and from 1282 to 1328 as the successor of his father Michael. In his reign Osman, the founder of the Ottoman empire, effected the conquest of Bithynia, and advanced within sight of Constantinople. Andronicus invited for his assistance from the west a multitude of Catalans, who defeated the Turks in two great battles, but were themselves driven out only after great trouble. His own grandson, Andronicus III., compelled him to abdicate in 1328, and shut him up in a monastery, where he died four years afterward.—**Andronicus III. Palæologus**, the Younger, grandson of the preceding, born in 1296, died June 15, 1341. He revolted against his grandfather in 1321, was made his colleague in 1325, but again revolted and deposed him in 1328. He reconquered Chios from the Genoese (1329), and took Epirus from the Albanians (1337). In 1333 the Turks took Nicea and made it their capital, and Andronicus joined the fruitless alliance of the western powers against them. He was also at war with the Catalans in Greece, and more successfully with the Bulgarians, Kiptchak Tartars, and Servians. His internal administration was moderate and conciliatory. He left the empire and his infant heir John under the guardianship of John Cantacuzenus.—**Andronicus IV. Palæologus**, grandson of the preceding, governed the empire in the absence of his father John VI., afterward conspired with the son of the sultan Murad to murder their fathers, and was captured and partially blinded. Escaping from a long imprisonment by the aid of the Genoese, he brought about a division of the empire between his father and himself, Andronicus making Selymbria his capital. The dates of these events are very uncertain. On the death of John VI. in 1391, Andronicus gave way to his brother Manuel II., and died a monk.

ANDRONICUS. I. Livius, the most ancient of the Latin poets, died about 221 B. C. He was an Italian Greek, whom the fortune of war had thrown into the hands of the Romans, and made the slave of M. Livius Salinator. His master gave him his liberty, and with it his own name of Livius. Andronicus then settled in Rome, acquired a perfect knowledge of the Latin language, and became a voluminous writer of dramatic and other poetry. But few fragments of his works have come down to us, of which the best edition is that of Düntzer (Berlin, 1835). Cicero considered them not worth reading. Horace avows that he would have contemplated their destruction with regret. **II.** Of Rhodes, a Peripatetic philosopher who flourished in the middle of the 1st century B. C. He is chiefly celebrated as the editor of Aristotle's works, to which he gave that arrangement which is to a great extent retained in the present editions. He wrote a general work on Aristotle, which contained a complete catalogue of his writings, and commentaries on

some of his physical, metaphysical, and logical treatises, all of which have perished.

ANDROS, an island of Greece, in the archipelago, the northernmost of the Cyclades, 21 by 8 m.; pop. in 1870, 19,674. It is mountainous, but has many fertile valleys, yielding wine, oil, silk, oranges, citrons, &c. Andro, or Castro, the capital, is situated on a shallow harbor on the E. coast; pop. 5,000. The Andrians submitted to the Persians in the invasion of Greece by Xerxes, and subsequently, after some resistance, to the Athenians. Still later, the island was successively annexed to Macedonia, Pergamus, and Rome.

ANDROS, an island of the Bahamas, giving name to a small group of islands which are but thinly inhabited, and the passages between which are intricate and difficult. The main island, 20 m. W. of New Providence, is of irregular shape, 65 m. long and 45 m. wide. It is chiefly composed of salt-water marshes and fresh-water swamps, in which there are a few elevated oases bearing excellent cedar timber. It has a population of about 800, nearly all colored, a school, and the privilege of sending one member to the Bahamas assembly.

ANDROS, Sir Edmund, an English colonial governor, born in London, Dec. 6, 1637, died there, Feb. 24, 1714. He was brought up at court, his father being an officer of the royal household. He was a major in Prince Rupert's dragoons, and in 1674 succeeded his father as bailiff of Guernsey. In the same year he was commissioned governor of New York, and received its surrender by the Dutch after their brief repossession of it. He administered its affairs in the interest of the duke of York, was involved in controversies with the surrounding colonies and with the French in Canada by his extensive claims to jurisdiction, and in 1680 seized the government of East Jersey, deposing Philip Carteret. He was recalled to England in 1681, cleared himself of several charges preferred against him, and retired to Guernsey. New England having been consolidated, Andros was appointed its governor general in 1686, under instructions which, while establishing religious toleration, forbade all printing, and authorized him to appoint and remove his own council, and with their consent to enact laws, levy taxes, and control the militia. Carrying out these instructions in a despotic manner, his government soon became very odious to the colonists. Connecticut having held out against him, he appeared in the council chamber at Hartford with an armed guard in October, 1687, and demanded the surrender of its charter, which is said to have been prevented by its sudden removal and concealment in a hollow tree afterward celebrated as the charter oak. Contemporary documents, however, seem to prove that no such event occurred, that Andros really possessed himself of the original charter, and that a duplicate had been concealed some time previously. (See Brodhead's "History of New

York," vol. ii., pp. 472-'3.) In 1688 New York and New Jersey were added to his jurisdiction, and Francis Nicholson was appointed lieutenant governor there. On the news of the revolution in England, the people of Boston imprisoned Andros and several of his officers, April 18, 1689, and the New England colonies restored their former governments, while Jacob Leisler usurped authority in New York. (See LEISLER.) In July he was sent to England by order of King William, with a committee of accusers, but was acquitted without a formal trial. In 1692 he was made governor of Virginia, where he made himself comparatively popular, but was removed in 1698 through the influence of Commissary Blair. In 1704-'6 he was governor of Guernsey. In 1691 Andros published a narrative of his proceedings in New England, which was republished in 1773.

ANDROSCOGGIN, a S. W. county of Maine; area, 400 sq. m.; pop. in 1870, 35,866. It has a fertile soil, and in agriculture ranks among the foremost in the state. The productions in 1870 were 7,800 bushels of wheat, 72,344 of corn, 20,404 of barley, 96,413 of oats, 371,391 of potatoes, 48,605 lbs. of wool, 559,213 of butter, 179,858 of cheese, and 50,787 tons of hay. The county has fine water power at Lewiston, produced by the junction of the Androscoggin and Little Androscoggin rivers, and there are numerous manufacturing establishments. The Portland branch of the Grand Trunk railroad, and the Maine Central and other lines, traverse the county. In 1870 there were 8,182 children attending school. Capital, Auburn.

ANDROSCOGGIN, or *Amerisoggin*, a river of New Hampshire and Maine. It is formed in Coös county, N. H., near the Maine boundary, by the union of the Margalloway river with the outlet of Umbagog lake, flows S. to the White mountains, and making a sharp bend to the E. about lat. 44° 20', enters the state of Maine, and joins the Kennebec river at Merry Meeting bay, about 18 m. above the entrance of that river into the ocean. Its length is 157 m., 66 of which are in New Hampshire.

ANDRYANA, *Alexandre*, a French champion of Italy, born in 1797, died in January, 1863. He was an officer of the French army till 1814, and subsequently joining the Italian revolutionists, he became a fellow prisoner of Silvio Pellico in the fortress of Spielberg, and wrote graphic *Mémoires d'un prisonnier d'état* (2 vols., Paris, 1837-'8; 4th ed., 1862). He took part in the French revolution of 1848, and in 1859 was commissary general to the army of occupation in Lombardy.

ANDUJAR, or *Anduxar*, a town of Spain, in Andalusia, province of Jaen, at the foot of the Sierra Morena, and on the right bank of the Guadalquivir, 50 m. E. N. E. of Córdoba; pop. about 13,000. It is a comparatively wealthy and very industrious place, its industry consisting chiefly in *alcarrazas*, a peculiar kind of jars made of red and white clay found

in the neighborhood, and highly esteemed for the power of keeping water cool in hot weather. The vicinity furnishes an extraordinary abundance of wheat, barley, oil, wine, and honey. The town contains several monasteries. It is supposed to be near the site of the ancient Illiturgis or Forum Julium. The capitulation of Baylen, so called from the neighboring place of that name, which was the opening of the French disasters in the Peninsular war, was signed in Andujar in July, 1808, after severe fighting around the town.

ANEGADA, a British West Indian island, the northernmost of the Virgin group and of the Lesser Antilles, 18 m. N. of Virgin Gorda; length 10 m., greatest breadth $4\frac{1}{2}$ m. It has but few inhabitants, who produce some cotton and food, and large quantities of salt from salt ponds. There is abundance of fresh water. Numerous shipwrecks occur, especially on a reef extending S. E. and S. from the E. end of the island.

ANEL, Dominique, a French surgeon, born in Toulouse about 1679, died about 1730. He acquired great fame by his invention of the probe and syringe still known by his name, and is also celebrated for his successful treatment of aneurism and fistula lachrymalis, upon which he published treatises. At the beginning of the 18th century he served as surgeon in the Austrian army, and in 1710 established himself at Genoa.

ANEMOMETER (Gr. *ἀνεμος*, wind, and *μέτρον*, measure), an instrument for measuring the force of the wind. Attention was first given to this subject by Dr. Croune in 1667, and instruments were contrived by him and by Wolfius and others in the last century. These have all given place, however, to recent inventions of more perfect construction. The first attempts were to measure the force of the wind by its pressure upon a vertical plane, kept in position by a spring or by a weight suspended by a cord wound around a conical spiral axis, which weight the wind would raise more or less according to the degree of pressure on the vertical plane. A bag of air opening into a glass tube which was shaped like the letter U, and contained a fluid which by compression of the bag was forced down one leg and up the other, was another contrivance for the same purpose. Another form of it was to dispense with the bag and turn one extremity of the tube against the wind, expanding it to a funnel shape, so that the wind might blow directly into it and press upon the surface of the fluid. The tube was drawn out to a small diameter in the curve at the bottom, so as to check the sudden fluctuations caused by irregular blasts of wind. By means of this simple instrument, Dr. Lind, who invented it, ascertained the force of the wind at different velocities by the height of the column of water raised by it. A gentle breeze, moving at the rate of nearly four miles an hour, raises a column of water $\frac{1}{15}$ of an inch, which is equivalent to a pressure of

$2\frac{1}{2}$ ounces upon a square foot. A high wind moving $32\frac{1}{2}$ miles per hour raises the column 1 inch, with a pressure of nearly $5\frac{1}{4}$ pounds on the square foot. A column of 3 inches indicates a pressure of $15\frac{1}{2}$ pounds, and a velocity exceeding $56\frac{1}{4}$ miles an hour. At 9 inches the wind is a violent hurricane moving $97\frac{1}{2}$ miles an hour, and exerting a pressure on the square foot of $46\frac{7}{8}$ pounds. The atmospheric pressure being a little over 2,000 pounds on the square foot, or equal to a column of water 33 feet high, the greatest force exerted by the wind is feeble in comparison with this.—A more complicated apparatus was invented by Dr. Whewell, and another by Mr. Osler, both of which have been used in England at the meteorological observatories and government institutions. Both are self-registering, and determine the force of the wind by the number of revolutions of a windmill fly, the axis of which by perpetual screws and toothed wheels is connected with the registering pencil. In Whewell's instrument the windmill with its wheels and vane is on a horizontal plate, which revolves on the top of a vertical cylinder. The pencil is attached to a little block of wood or nut, through which passes a screw from the horizontal plate above to a circular rim below the cylinder, all which revolves around the cylinder as the wind changes. A straight rod also goes through the pencil block or nut, up and down which it slides as the screw turns. According as the wind blows gently or strongly, this screw turns slowly or fast, and carries the pencil down the cylinder at a proportional rate. Its point reaches the surface of the cylinder and marks upon it its position, and as the frame turns with the change of direction of the wind, the course of the wind is registered upon the face of the cylinder. For this purpose it is divided by vertical lines into 16 or 32 equal parts corresponding to the points of the compass. This instrument is deficient in not recording the time during which each wind blows, nor the times of its changes, nor its force at any particular moment. It merely gives the order of the changes, and the entire quantity that blows from each point. This is known by the vertical length of the pencil mark in each division of the cylinders corresponding to the courses. It is defective also by the friction of its machinery. Osler's instrument, constructed on similar principles, is more complicated than Whewell's. Its register is divided by lines into spaces, which represent the 24 hours of the day, and in these spaces pencils inscribe lines, one of which indicates the direction, another the pressure of the wind, and a third, connected with a rain gauge, the quantity of rain which has fallen at every hour. The register moves along by clockwork under the pencils, and at the meteorological observatory at Greenwich a new one is employed every day. In the royal exchange in London one of these instruments is in use with a register made to last a week. By the lines inscribed on the

register the integral or quantity of the wind can be calculated that has blown to each point of the compass during the periods of the observations; and thence the resultant, or average effect of all the winds.—The instrument now in use in the United States office for weather reports is Robinson's anemometer, which consists of four horizontal arms (see figure) radiat-

ing from a central point, at which is a vertical axis of revolution. A hollow hemispherical cup is attached to each arm in such manner that when the wind is pressing upon the concave side of a cup on one arm, the cup on the opposite arm presents its convex side toward the wind. The wind exerts more pressure on the concave side than on the convex, and hence causes the arms to revolve. The rate of revolution per minute gives the velocity of the wind. Each instrument has to be tested by placing it upon a moving body on a calm day. In this way it is easily found what the number of revolutions is which the instrument will give for any velocity; it is then placed upon a high building, and its axis attached to a recording apparatus similar to that described above.—Biran's anemometer is an instrument for measuring and registering the quantities of air which circulate through the passages of mines. It was invented in consequence of the recommendation of a committee appointed by the British house of commons, that the use of such an instrument should be adopted as a precaution against the explosions in coal mines. It is a disk of a foot diameter, made to revolve when placed in a current of air, and furnished with registering wheels like those upon a gas meter. Any want of attention on the part of those having charge of supplying the required current of fresh air is thus readily detected.

ANEMONE (Gr. *ἄνεμος*, wind), as many species grow in elevated windy places), a genus of plants of the family of *ranunculaceae*, Jussieu. The leaves of the stem are generally ternate, forming an involucre which is more or less distant from the flower; the calyx corolla-like, with from 5 to 15 colored petals, longer than the stamens; carpels numerous, ending in persistent styles. About 60 species are cultivated on account of their beauty, succeeding best in light loamy soils. They are propagated by division, offsets, and seeds; the greenhouse species from cuttings in light loam under glass. The colors of the flowers predominate in the following order one over the other: white, yellow,

blue, reddish white, purple, red, striped, whitish, creamy violet. Their recommendations for a place in the garden are: a fine dense foliage

Anemone hortensis.

of beautiful green color; involucre green, and distant about $\frac{1}{4}$ from the flower; stem straight, light; flowers globose, petals large, rounded, with an unguis (nail) of different color. The native countries of the species are, in order of prevalence, Europe, especially the south, North America, Siberia, the rest of Asia, South America, South Africa. The most valued are: The *A. hortensis* and *stellata*, often flowering the second year, easily doubled by culture; flowering from mid-April to the end of May. *A. japonica*, of Europe; root tuberous; flowers purple; attains a foot in height; a variety is crimson with green centre. *A. ranunculoides*, of Europe, about 6 inches high. *A. apennina*; leaves ternate; many narrow, blue petals. *A. narcissifolia*, of Switzerland; 10 inches; umbellated purplish and yellow. *A. vitifolia*, of Nepal, *japonica*, and *elegans* (also from Japan), recommend themselves by their strong and tall frame ($1\frac{1}{2}$ to 3 feet), and by the beauty of their flowers. *A. capensis* or *arborea*; stem woody, though but 7 inches high; flowers reddish outside, white inside. *A. pulsatilla*, common in Europe; 10 inches high; flowers large violet; foliage hairy. *A. coronaria*, of Asia Minor; hard to be raised from seed in this country.—A new genus has been separated from the anemone, under the name of *hepatia*, to which belongs the beautiful species commonly called anemone that adorns our forests in early spring; leaves leathery, dark green on the upper side, liver-brown on the lower; flowers numerous, of all shades of white and bluish purple. Both are allied to the clematids, hellebores, actæas, and crowfoots, with which they form the 41 genera of *ranunculaceae*. The *hepatia* was employed of old in liver complaints, from the belief in its sympathy with

that organ. Pulsatilla is a much used remedy in the homœopathic materia medica.

ANEMOSCOPE (Gr. *ἀνεμος*, wind, and *σκοπεῖν*, to look), a wind indicator, or weathercock. The term is, however, only applied when the weathercock is attached to a spindle which passes from the vane into an apartment below, and there by an index upon a compass dial indicates in what direction the wind blows. For expressing this direction the plan has been adopted of dividing the great circle of the horizon into 32 parts of 11° 15' each, and calling the directions of the wind successively: N., N. by E., N. N. E., N. E. by N., N. E., N. E. by E., E. N. E., E. by N., E. E., E. by S., E. S. E., S. E. by E., S. E., S. E. by S., S. S. E., S. by E., S., S. by W., S. S. W., S. W. by S., S. W., S. W. by W., W. S. W., W. by S., W., W. by N., W. N. W., N. W. by W., N. W., N. W. by N., N. N. W., N. by W., N. The latest improvement of the anemoscope is to attach a recording clockwork to the dial plate, so that not only the direction of the wind, but the time that it blows in any direction, is permanently recorded. Such an arrangement is now in operation at the meteorological observatory in the Central Park, New York.

ANERIO. **I. Felice**, an Italian musician, born in Rome about 1560, died about 1630. In 1594 he succeeded Palestrina as composer of the pontifical chapel. A great number of his compositions have been published, and his unpublished pieces have been preserved in the archives of the basilica of the Vatican and in the pontifical chapel. **II. Giovanni Francesco**, brother of the preceding, born in Rome about 1567, was for many years chapel master of the king of Poland and of the cathedral of Verona, and subsequently a teacher of music at the Roman seminary. He was one of the first Italian composers who made use of quavers, semi-quavers, and demi-semi-quavers. Many of his musical compositions have been published.

ANEROID. See **BAROMETER**.

ANEURIN, a Welsh bard, who was the leader of the mediæval Britons in the battle of Cattraeth, and who celebrated in heroic verse the deeds of that day. His work is still preserved in the literature of Wales. He died about 570. It is supposed that this poet was either identical with or the brother of the historian Gildas.

ANEURISM (Gr. *ἀνευρησμός*, a widening or extension), a term used in surgery to signify a vascular tumor or enlargement, arising from the morbid distention of an artery. It is much more common in some arteries than others, but any artery of the body is liable to it. The corresponding disease and enlargement of a vein is termed varix. An artery is composed of three coats or membranes which form the walls of a strong, elastic, and distensible tube. In a healthy state, the tube maintains a certain diameter under the ordinary impulse of the blood; but when the walls of an artery become diseased, they yield before the constant pressure of the circulating fluid, causing the diseased

part to form a bag or tumor. This bag enlarges as the diseased walls distend; and the inner and middle coats, being less resisting than the outer, especially in a diseased state, give way and burst, leaving the outer coat alone to form the walls of the aneurismal tumor. This admits of a considerable amount of distention; but it eventually bursts, and then the unrestrained current gushes out with violence, and the patient dies from loss of blood. Sometimes, however, the dense cellular sheath of the artery, though very distensible, is strong enough to retain the blood for a time after the rupture of the proper walls of the artery, and the aneurismal sac may thus be very much enlarged, and not give rise to fatal hæmorrhage. At times, in fact, this external sac allows the ruptured walls within to partially collapse; the current flows as usual; the blood in the external sac coagulates and forms a clot around the ruptured part beneath; the clot increases from its stagnant state outside the current, and eventually plugs up even the ruptured parts, extending into the diseased artery and plugging up the tube, thus forcing the current to flow more abundantly through collateral channels, enlarging the walls of neighboring arteries, and forming a spontaneous cure for the original disease. This is a very rare occurrence. The tumor usually enlarges by degrees, pressing upon the nerves and tissues near it, and causing pain as well as absorption of the soft or bony structures against which it presses. An aneurismal tumor always pulsates strongly, and can generally be distinguished from all other tumors by this characteristic feature. It sometimes happens, however, that an artery pulsating beneath an abscess or an ordinary tumor causes the latter to simulate to some extent this pulsating character, and hence arise at times errors of diagnosis of a serious character; real aneurisms have been mistaken for abscesses lying upon a pulsating artery, and when opened under this impression to let out pus, the blood has gushed out from an aneurismal tumor, and the error has proved fatal. Ruysch relates that a friend of his opened a tumor near the heel, not suspecting it to be an aneurism, and the hæmorrhage, though stopped at last, placed the life of the patient in great danger. Boerhaave was consulted by a patient on a swelling of the knee, and, suspecting it to be an aneurism, cautioned him against having it opened; but it was opened by another person, and the man died on the spot. It is said that Ferrand, the head surgeon of the Hôtel Dieu in Paris, mistook an axillary aneurism for an abscess, plunged his bistoury into the swelling, and killed the patient. Such mistakes, however, can hardly happen now, as all the best works on surgery give ample instructions on the means of diagnosis in this and other important diseases.—The cure of aneurism consists in the obliteration of the diseased portion of the artery, by passing a ligature around the sound portion of the vessel at some distance

above the locality of the tumor. The merit of this method of cure is due to the celebrated John Hunter, who, observing that the old practice of passing the ligature upon the artery immediately above the tumor often failed, was led to think that the arterial walls, being diseased near the tumor, could not sustain the process of inflammation necessary to cause the tissues to adhere; and consequently he undertook to tie the femoral artery in a case of popliteal aneurism, and was perfectly successful. Since then his method has been universally adopted. Recently many attempts have been made, some of them with considerable success, to produce a similar result, either by continuous pressure over the artery kept up for a day or two, or by a ligature applied temporarily to the artery and withdrawn as soon as coagulation has taken place in the aneurism and the neighboring portion of the artery. By whatever means this is accomplished, the flow of blood is stopped in the large vessels below the ligature; but the secondary vessels communicate with each other so abundantly in all parts of the limb, by what is called anastomosis, that the blood soon finds its way through these smaller channels, and enlarges them by slow degrees to suit the wants of nutrition.

ANFOSSI, Pasquale, an Italian composer, born in Naples in 1729, died in Rome in 1797. He was a pupil of Sacchini and Piccini, the latter of whom in 1771 procured him an engagement in Rome. His first successes were in 1773, with the opera *L'Incognita perseguitata*, and several others immediately succeeding. His serious opera *L'Olimpiade* having failed, he went to Venice, and in 1780 to Paris, where his *Incognita perseguitata*, with a French libretto, was not well received. In 1783 he was manager of the Italian opera in London, and in 1787 returned to Rome, where he enjoyed henceforth uninterrupted popularity. Of his works, which are now little known, the best are *L'avaro*, *Il curioso indiscreto*, and *I viaggiatori felici*.

ANGARA, a river of Siberia, which enters Lake Baikal at its N. extremity, under the name of Upper Angara, leaves it near the S. W. end as the Lower Angara or Upper Tunguska, flows past Irkutsk, pursues a N. and W. course for about 750 m., until it is joined by the river Tehadobet, continues in a westerly direction about 250 m. further, and empties into the Yenisei, E. of Yeniseisk.

ANGEL (Gr. ἄγγελος, a messenger), a name given in Jewish and Christian theology to certain spiritual beings endowed with superhuman powers of intelligence and of will. They are frequently mentioned in the Old as well as the New Testament as immediate instruments of Divine Providence. In Scripture, however, the original word not unrequently has its primary signification of messenger, even where rendered angel in the Vulgate and the English version. They are regarded as pure spirits in whose existence

there is nothing material. They often appear in the Scriptures with bodies and in the human form; but it was in the early church and still is a matter of theological dispute whether these bodies and this form were only assumed by them for a time for the special purpose of conversing with men. Besides these good angels, the church recognizes a class of "fallen angels," who left their first estate and are now "angels of the devil." The second council of Constantinople, contrary to the opinion of Origen, declared that there are different classes of angels; and since Dionysius the Areopagite the opinion that there are nine classes of angels has become prevalent in the Catholic and eastern churches. It was a common opinion among the fathers of the early Christian church that every individual is under the care of a particular angel who is assigned to him as a guardian; but Protestant theology finds nothing in the Bible to support this notion. While the older Protestant churches, in general, agree in the doctrine of the angels with the Catholic and eastern churches, they reject as unbiblical the opinion of the latter that it is good and useful to ask the good angels for their protection, aid, and intercession, and to venerate their images. According to the critical school of Protestant theology, the belief in angels was foreign to the early religion of the Jews, and derived from the Persians about the time of the Babylonish captivity. Several prominent Protestant theologians of modern times, like Schleiermacher and Hase, deny the existence of angels altogether, regarding them as creatures of Biblical poetry; others, like Martensen and Rothe, endeavor to establish the doctrine on a new speculative basis; while Swedenborg and his followers regard the angels of the Bible and all spiritual creatures as disembodied human beings, who have at some time existed in the flesh in this or some other world. (See NEW JERUSALEM CHURCH.) Pictures of the angels were expressly allowed by the second council of Nice. They are usually represented in the human form, in the male sex, as beautiful youths; the rapidity with which they are supposed to carry out the commands of God is symbolized by wings, flowing garments, and naked feet; harps and other musical instruments which are placed in their hands are intended to indicate that they incessantly sing the praise of God.

ANGEL (in French *ange d'or*, *angelot*, *angelot-tus*, *angelus*), a coin so named from the figure of

the archangel Michael and the dragon stamped on one side of it. It was originally a French coin, first struck in 1340, with the French arms on the obverse. It was introduced into England in the reign of Edward IV., and called angel. Its value was then 6s. 8d.; under Henry VIII. it was raised to 8s., and under Charles I. to 10s., after which its coinage ceased.

ANGEL FISH, the common name of the *squatina angelus* (Dum.), a representative of the family of *squatinae*, intermediate between the sharks and rays. The body is flattened above and below, and discoid in shape on account of the broad pectorals and ventrals, as in rays; the mouth is very wide and at the end of the snout; the eyes small and on the dorsal aspect, with the large spout holes behind them; the head rounded anteriorly; the pectorals separated from the head by a furrow in which are the long and closely approximated gill openings; two dorsals, both on the tail, further back than the ventrals; tail keeled on the sides, and the caudal nearly or quite symmetrical; male claspers small; scales conical, with a terminal point; teeth conical, irregular, with interspaces. It is the only genus of the family, and this, the best known species, is called shark ray from its appearance, angel fish from the resemblance of the expanded pectorals to wings, monk fish from

Angel Fish (*Squatina angelus*).

its rounded head seeming to be enveloped in a cowl, and fiddle fish from its general shape. It attains a length of 7 or 8 feet, and is rough and mottled with brown and bluish gray above, smooth and dirty white below; the lighter pectorals are bordered with brown, the nostrils covered by a ciliated membrane, and along the back is a row of spines. It is not uncommon in the European seas, and in the Mediterranean, where it was known to Aristotle, in whose time, as now, the rough skin was used to polish wood. It is gregarious, fierce and dangerous to approach, hideous, very voracious, swimming near the bottom, and feeding on flat fishes and other species living in the mud and sand. The young are produced alive in June. The flesh is white, coarse, and taste-

less, though formerly esteemed as food. A species has been described on the American coast as the *S. Dumerili* (Lesueur).

ANGELI, Filippo, an Italian painter, born in Rome, lived in his youth in Naples, whence he is sometimes called the Neapolitan, and died in Florence about 1645. He excelled in landscape painting, and was one of the first to observe the strict rules of perspective in works of that class. His works are rare and dear.

ANGELICO, Fra, the familiar appellation of one of the most celebrated of the early Italian painters, born at Mugello, Tuscany, in 1387, died in Rome about 1455. At the age of 20 he entered the monastery at San Domenico, near Fiesole, where he took the cloistral name of Giovanni da Fiesole. Previous to this time, according to Vasari, he had borne the name of Giovanni Guido di Mugello, and according to others that of Santi Tosini. Here he passed the remainder of his days in the devout discharge of his religious duties and the pursuit of his art. From the beauty of his angels and glorified saints he was called by his countrymen *il beato* (the blessed) and *angelico* (the angelic). He painted only sacred subjects, would never accept money for his pictures, and never commenced them without prayer. He visited Rome at the command of Nicholas V. to decorate the papal chapel. The pope offered to make him archbishop of Florence, a dignity which his humility would not permit him to accept, but which he succeeded in procuring for a brother monk. He painted frescoes in his own monastery and in the church of Santa Maria Novella at Florence, and numerous easel pictures, of which the Louvre possesses a noble specimen, the "Coronation of the Virgin." In many details of art he was excelled by his contemporaries; but, in the language of Mrs. Jameson, "the expression of ecstatic faith and hope, or serene contemplation, has never been placed before us as in his pictures."

ANGELINA, an E. county of Texas, bounded N. E. by Angelina river, and S. W. by the Neches; area, 1,059 sq. m.; pop. in 1870, 3,985, of whom 742 were colored. The county abounds in heavy timber, oak, pine, beech, holly, hickory, magnolia, sweet gum, sugar maple, ash, sassafras, cane brakes, cypress, mulberry, &c. The soil is black, and in the bottoms sandy. Corn, cotton, sugar cane, rice, and tobacco are the principal products. Large numbers of hogs are raised and sent to market. There are two steam saw mills, but no other manufactories. Petroleum is abundant. Capital, Homer.

ANGELL, Joseph K., an American writer on law, born in Providence, R. I., April 30, 1794, died in Boston, May 1, 1857. He graduated at Brown university in 1813, edited the "United States Law Intelligencer and Review" from 1828 to 1831, and was for several years reporter of the decisions of the supreme court of Rhode Island. He published treatises, between 1824 and 1854, on the "Common Law in relation to

Water Courses," the "Right of Property in Tide Waters," the "Law of Private Corporations," the "Limitation of Actions," the "Liabilities and Rights of Common Carriers," and the "Law of Fire and Life Insurance." At the time of his death he was employed in preparing a treatise on the "Law of Highways," which was completed by Thomas Durfee. Lord Brougham esteemed his work on the "Limitation of Actions" very highly.

ANGELN, or **Anglen** (Lat. *Anglia Minor*; Dan. *Angel*), a district about 300 sq. m. in extent, in Schleswig, bordering on the Baltic and the bay of Flensburg. It is the only territory on the continent which has preserved the name of the tribe of Angles. The present inhabitants are distinguished for bodily strength, industry, and morality.

ANGELO, **Michel**. See **BRONAROTTI**.

ANGELUS DOMINI, a short form of prayer which Catholics are accustomed to recite in honor of the incarnation, at sunrise, noon, and sunset, at the ringing of a bell, called the Angelus bell. This custom originated with the ringing of the bells on the eve of festivals. Pope John XXII. (1327) ordered that at the ringing of the bells on these occasions all the faithful should recite three Ave Marias. The council of Lavaur (1368) ordered that the bell should be rung also at sunrise. The Angelus at noon is attributed by some to Pope Calixtus III. (1456), and by others to King Louis XI. (1472). Mabillon thinks that the Angelus as now practised is of French origin, and became general at the beginning of the 16th century.

ANGELUS SILEMUS, whose real name was JOHANN SCHEFFLER, a German philosophical poet, born at Breslau, in Silesia, in 1624, died there, July 9, 1677. After receiving a medical degree, he travelled through Holland, became court physician to the emperor Ferdinand III., embraced in 1653 the Roman Catholic faith, afterward became a priest and councillor to the bishop of Breslau, and finally retired to a cloister. He is the author of a system kindred to that of the mystic pantheists Tanler and Böhme, of whose writings he had been a student. His peculiar faith is mainly expressed in poems, of which he published collections, with the titles of "The Cherub's Guide Book," "Spiritual Pastorals," "The Troubled Psyche," and "The String of Pearls."

ANGERMAN, **Angerman-aa**, or **Angerman-elf**, a river of northern Sweden, rises in the lake of Kult, on the Norwegian frontier, and, after flowing S. E. through the provinces of Westerbotten and Westernorrland for 240 m., falls into the gulf of Botlnia, 12 m. N. of Hernösand. It is navigable to Sollefteå, about 60 m. It passes through many lakes, contains numerous islands, and is noted for its fine scenery.

ANGERMÜNDE, a town of Prussia, in the Potsdam district of the province of Brandenburg, on Lake Münde and about 40 m. by railway N. E. of Berlin; pop. in 1871, 6,412. It trades in wool, tobacco, and yarn, and there are fish-

eries, breweries, and manufactories of hosiery and cloth.

ANGERS (anc. *Juliomagus*, in the territory of the Andecavi or Andegavi), an old city of France, capital of the department of Maine-et-Loire, situated on the Mayenne, 4 m. from its junction with the Loire, 161 m. S. W. of Paris, on the line of the Tours and Nantes railway; pop. in 1866, 54,791. It has a college and seminary, a government sail-cloth manufactory, and various manufactories of linen, woollen, cotton, and silk stuffs; also tanneries and sugar and wax refineries; and contains the mother house of the Sisters of the Good Shepherd. In the vicinity are extensive slate quarries. Its chief curiosities are the ruins of a castle of the old dukes of Anjou, a cathedral containing the monument of Margaret of Anjou, remains of a Roman aqueduct, and a museum with 600 pictures. It has a library, a botanical garden, and a school of arts and trades. The university, founded in 1246, and once among the most famous schools of learning in Europe, and the royal academy of belles-lettres, established by Louis XIV. in 1685, were destroyed during the revolution. In 1585 the castle was surprised by the Huguenots, and in 1793 the city was besieged by the Vendéans, when the inhabitants endured great sufferings. Lord Chatham and the duke of Wellington studied here at a military school. David the sculptor was born here.

ANGHIERA, **Pietro Martire d'** (called in English **PETER MARTYR**), an Italian historian and geographer, born at Arona on Lago Maggiore in 1455, died in the city of Granada in 1526. He was of noble extraction, and at the age of 22 went to finish his education at Rome. In 1488 he accompanied the Spanish ambassador to Spain, where he served in two campaigns against the Moors, and then entered the church, and opened a school for the young nobility. In 1501 he visited the sultan of Egypt on a mission from King Ferdinand, and took occasion to explore the pyramids and some of the most striking remains of antiquity. The king obtained for him the title of apostolic protonotary, and in 1505 made him prior of the church of Granada. Charles V. afterward presented him with a rich abbey. The historical works of Peter Martyr are among the best sources of information respecting the important age in which he lived. His literary remains comprise his *Opus Epistolarum*, a collection of letters in 38 books, in which almost every event of public importance from 1488 to 1525 is recorded; a history of the new world entitled *De Rebus Oceanicis et Orbe Novo*, written from original documents furnished by Columbus, and from statements made to the council of the Indies, of which he was a member; an account of newly discovered islands and their inhabitants; and a report of his visit to Egypt, under the title of *De Legatione Babylonica*.

ANGILBERT, **Saint**, minister of Charlemagne, and the most distinguished poet of his age, born

in Neustria, now Normandy, died Feb. 18, 814. He studied under Alcuin with Charlemagne; received Bertha, the daughter of that prince, in marriage; was appointed prime minister of Pepin, king of Italy; and after returning to France was intrusted with a portion of the government, and became secretary and minister to Charlemagne. With the consent of his wife he entered in 790 the monastery of Centule or St. Riquier, of which he became abbot in 794. He often left his retreat to attend to interests of state or to ecclesiastical affairs, and made four journeys to Rome, in the last of which he accompanied Charlemagne and saw him crowned emperor of the West. Angilbert was a correspondent of Alcuin, and was called the Homer of his time. His poems and a history of the abbey of Centule are marked by much elegance.

ANGINA PECTORIS (Lat. *angere*, to suffocate), a disease so named from a sense of suffocating contraction or tightening of the chest, over the sternum, causing anguish and fear of sudden death. A sudden attack of severe pain in the lower part of the chest, commonly inclining to the left side and extending down the left arm, is the most prominent symptom of the disease. The pain sometimes affects the right arm, and is often attended with palpitation of the heart and a sensation of fainting; but the latter symptoms are not constant. The pulse is commonly accelerated, though otherwise very slightly affected. The countenance is pallid, and the expression anxious and depressed. There is no regular interval between the paroxysms nor distinct warnings of return. They come on suddenly and unexpectedly, from slight causes, and often when no immediate cause can be assigned, and last from a few minutes to half an hour or more. The health is often tolerably good between the intervals when first the disease comes on, but by degrees it fails, and various uneasy sensations distress the patient in the intervals of paroxysms. The respiration becomes labored and digestion difficult.—The nature of this disease is still involved in some obscurity. It seems to be mainly an affection of the nerves, complicated with symptoms of a rheumatic or a gouty nature, and often also with disease of the vessels. The morbid appearances which are found after death are most frequently ossification of the small vessels that supply the heart itself, commonly called coronary arteries; ossification of the valves of the heart; excessive accumulation of fat on its external surface; enlargement of its cavities, and change of structure in its muscular substance, which becomes soft and flabby, thin, and easily torn. Although the hardening of the coronary arteries and the valves of the heart has been generally called ossification, the term is a misnomer; for there is no real ossification, but a hardening and thickening of the parts by earthy deposits, such as are observed in the blood vessels and in the joints of certain rheumatic and gouty constitutions. The degenerations and morbid appearances of the

vessels, valves, and tissues of the heart are therefore often quite analogous to those observed in other parts of the body, in patients suffering from gout and rheumatism and certain kinds of aneurisms, with morbid deposits in the distended and thickened walls of the arteries. Still, these symptoms are not constant, and cases are not infrequent in which the patients have suffered much during life from attacks of angina pectoris, and yet in which no morbid changes whatever have been found after death, either in the heart or blood vessels. Much has been done to ascertain the primary seat and the nature of this disease, but physicians are not as yet unanimous in their opinions. The majority believe it to be primarily a nervous affection, the nerves at fault being those which supply the lungs and the heart. It differs from neuralgia properly so called in several most important features, although the sudden violent shooting pains are not unlike those of tic douloureux and other forms of severe neuralgia. In so far as the latter disease may be chiefly caused by swelling and inflammation of the sheaths of the nerves, there is a strong analogy; but careful observation suggests that the gouty or rheumatic diathesis, whatever be the nature and the cause of that peculiar cachexia, lies at the bottom of the disease of the heart known as angina pectoris; and that the neuralgic pains are no more violent and sudden in the paroxysms of this disease than they are in gout and certain forms of rheumatism. The seat of the disease, however, renders the same paroxysms more alarming. There are undoubted instances on record in which angina pectoris has been completely cured, the paroxysms growing more moderate in character and less frequent in their recurrence, and finally passing off altogether, leaving the patient in a state of sound health. On the whole, however, the malady is a dangerous one, having a tendency to become worse rather than better, the patient's health gradually deteriorating, and death finally taking place, either from syncope during one of the paroxysms, or from one of the complications mentioned above, by which the disease is so frequently accompanied.—Angina pectoris seldom affects young people. It most frequently occurs in the meridian of life or in the descending phase of existence. It is much more frequent in the male than in the female. Sir John Forbes and M. Lartigue found that out of 155 cases 140 were males and only 15 females. The following list of 64 cases by M. Lartigue shows its comparative frequency at different ages: At 17 years, 1; 21, 1; 29, 1; 30 to 35, 6; 40, 2; 41 to 50, 11; 51 to 60, 25; 61 to 70, 13; 71 to 77, 4. When the disease is far advanced, paroxysms are easily brought on by mental or moral emotions. Absolute rest of body and tranquillity of mind are necessary while the paroxysm lasts. The head and chest should be raised, and the body seated in an easy chair; and where the disease is far advanced, the patient should sleep in this position.

ANGLE, a portion of space between two lines or between two or more surfaces intersecting each other. Geometry distinguishes four kinds of angles: plane, spherical, dihedral, and polyhedral. 1. *Plane angles*. When two lines are situated in the same plane and not parallel to each other, they intersect at some point, and around this point of intersection they form four plane angles; the point of intersection is called the vertex, and the lines the sides of the angles. If all the four angles thus formed are equal, they are called right angles, and the lines are said to be perpendicular to one another; when not equal, those smaller than a right angle are called acute, and those larger obtuse angles. Angles are measured by degrees, which are nothing but angles so small that 360 of them are situated around one point, and therefore 90 in a right angle. For practical measurement of angles the circumference of a circle is divided into 360 equal parts (see fig. 1), and its centre

Fig. 1.—Plane Angles.

Fig. 2.—Spherical Angles.

laid on the vertex of the angle, in which case the parts of the circumference between the sides of the angle will indicate the number of degrees contained in the same. Each degree is again divided into 60 parts called minutes, and each minute into 60 seconds. The whole circumference of the circle is therefore subdivided into 1,296,000 seconds, which is about the limit of accuracy of astronomers in measuring angles at the firmament. When angles have curved sides (as represented in fig. 2), tangents are drawn to the curves at the vertex, and the angle these tangents make with one another is measured. 2. *Spherical angles*. Under this name is designated the space included between two arcs of great circles, drawn on a sphere. A D and B D, fig. 2, form together a spherical angle, which, if the plane B O E D is perpendicular to the plane A O C D, is a spherical right angle: the intersections of the meridians with the equator of the earth are such right angles, while the intersections of the meridians at the poles form a number of acute spherical angles. The angles which the astronomers measure in their celestial triangles are all spherical angles. 3. *Dihedral angles* are formed by the intersection of two planes. The planes A B C D and A B F E, fig. 3, form a dihedral angle; the line of intersection, A B, is called the edge, and the planes are called the faces. Such angles are measured by the plane angle formed when passing a plane perpendicu-

lar through the edge, or, what is the same, drawing two lines O T and S T from the same point in the edge A B, perpendicular to the

Fig. 3.—Dihedral Angles.

same, and one in each plane; the arc ST is in that case the measure of the dihedral angle. 4. *Polyhedral angles* are the spaces included

Fig. 4.—Trihedral Angle.

between three or more planes which intersect at one point. Thus O, fig. 4, is the vertex of a trihedral, and O, fig. 5, the vertex of a tetrahedral angle, respectively bounded by three and four faces. As an arc of a circle is used for measuring plane and dihedral angles, so a portion of the surface of a sphere, of which the centre is at the vertex, is used to measure polyhedral angles.—**Angle**

Fig. 5.—Tetrahedral Angle.

of Total Reflection. When a ray of light falls on a polished surface separating a transparent denser medium from a similar rarer one, it will be reflected and refracted, that is, split up into two rays; one of which will be thrown back, and the other will pass on and be diverted more or less from its course. Such a splitting up of a ray of light always takes place when it passes from a rarer into a denser medium. But when the light passes from a denser into a rarer medium, for instance, from glass into air, this will not be the case under all inclinations of the ray. When the angle of incidence is not very acute, no refraction, but total reflection, will take place. Let A B O represent a cross section of a glass prism; then the ray D R will be split up, being reflected to R E and refracted to R R, because the angle of incidence, D R Q, is very acute, the ray F T, however, making with the perpendicular T P a less acute angle. As F T P is only reflected in the direction T G, and not refracted at all, it cannot pass out of the prism at T, and this constitutes there a case of total reflection. The minimum number of degrees required

ANGLING, the art of taking fish by means of the rod, line, and hook. It probably was never a popular recreation with any of the more civilized peoples of antiquity, but in England it early became a favorite sport. One of the earliest books printed in the English language is a small folio republication of "The Boke of St. Albans," issued in 1496 by Wynkin de Worde, and containing a "Treatise of Fishing with an Angle." The fish which have always been the keeneest object of the skilful fisherman's pursuit, both as the best on the board when taken, and as affording the greatest sport to the taker, are those of the salmon family, including the true or sea salmon, the sea trout, the lake trout of several varieties, and the brook trout. For fly-fishing, the rod for salmon fishing should be from 16 to 18 feet long, pliable, elastic, and tapering; with a reel capable of containing 100 yards of strong, evenly plaited hair line, tapering gradually from end to end, and terminating in a leader of the best round silkworm gut, to which is attached the foot length of a large, gaudily colored salmon fly. The trout fly rod is of the same general character, but shorter, lighter, and capable of being easily managed with one hand; whereas the salmon rod requires the use of both, and takes a strong and practised man to wield it with effect through a whole day's fishing. From 10 to 12 feet will be long enough for an ordinary fly rod, and from 30 to 40 yards of line will be an ample allowance. Trout flies are much smaller, and usually much more gravely colored, than the salmon flies most in use. The object in fly-fishing is to throw the fly well out, and, letting it drop on the water as lightly and naturally as possible, to keep it playing and dancing in the eddies, with motions simulating those of a drowning insect. The fish of America most valued by the angler are the trout, striped bass, the black bass of the lakes, and the rock bass; several varieties of pike, from the gigantic musealonge of the basin of the St. Lawrence down to the little Long Island pickerel, which rarely exceeds 10 inches in length; the pike perch, known as the glass-eye or Ohio salmon, in the western waters; the perch; the carp; and many other species and varieties, of various degrees of size and excellence, down to the little, many-colored pond fish.—The principal differences between bait-fishing and fly-fishing consist in the use of the fish or the worm with trolling, spinning, roving, or stationary tackle. Trolling and spinning are both practised with dead fish, to which the angler, by the play of his wrist and line, conveys a motion in the water similar to that of swimming. The bluefish and Spanish mackerel are caught by trolling, but instead of bait the hook is attached to a piece of bright metal or bone, shaped somewhat like a small fish. In spinning, swivels are used, and a series of small hooks, tied on fine gut, are applied to the bait externally, which is fastened to the line head upward, with a

slight curve given to the tail, so that the action of the swivel and the force of the current cause it to play with a rotatory motion in the water. Roving is performed with a small live fish, hooked, so as not to injure him seriously, through the dorsal fin or the lip, and suffered to swim about at his own pleasure, within such limits as are accorded to him by the length of line. Bottom fishing requires a weighted line, a cork float, and worm, paste, or shellfish bait; it is adopted for trout and perch fishing in rivers, and for taking many sorts of sea fish in bays and tideways.—The following are the titles of a few of the most valuable works on angling, published within a few years: Serope's "Days and Nights of Salmon Fishing"; "The Book of the Salmon," by Andrew Young; Sir Humphry Davy's "Salmonia"; Pulman's "Vade Mecum of Fly-fishing for Trout"; "Handbook of Angling," by Ephemera; "The Rod and Line," by Hewett Wheatley; Ronald's "Fly-fisher's Entomology." These are all English works, to which may be added the following American publications: Dr. Bethune's edition of Izaak Walton's "Complete Angler," Frank Forrester's "Fish and Fishing," Brown's "Angler's Guide," Lanman's "Adventures," Roosevelt's "Superior Fishing" and "Game Fish of the North," and G. C. Scott's "Fishing in American Waters."

ANGLO-SAXONS, the Teutonic people who in the 5th and 6th centuries passed over from their territory in and near the Cimbric (Danish) peninsula to the island of Britain, then just abandoned by the Romans. They first acted as auxiliaries to the British against the Piets and Scots, but afterward subdued and overspread the country, establishing themselves as its permanent inhabitants, while the aboriginal races gradually disappeared before their rapid growth. They were principally collected from three nations, the Saxons, Angles, and Jutes, all members of the great Saxon confederation, a rough union of Teutonic tribes effected during the 4th century, under the Saxon hegemony, for mutual advancement and protection. (See SAXONS.) The Saxons inhabited the country called North Albingia or Eala Saexcn, extending from the Elbe to the Eider, on the W. side of the Cimbric peninsula, and divided into Ditmarsia, Stormaria, and Holsatia—districts which still retain these names. The Jutes inhabited South Jutland, now Schleswig. The territory of the Angles was probably the district of Angeln, now also within the limits of Schleswig. These tribes, celebrated for naval prowess, had made several piratical expeditions to the British coast before the abandonment of the island by the Romans. According to the statement of old histories, the details of which are not now fully credited by critical writers, it was the knowledge of them thus acquired by the Britons that led these latter to call upon them for aid, when, about A. D. 449, Vortigern, the leading British chief of the time, found him-

self unable to withstand the increasing inroads of the Picts and Scots, the barbarous tribes inhabiting the north of the island. In response to his invitations, it is said, the Saxon chiefs Hengist and Horsa, who were visiting the coast for some unexplained but probably predatory purpose, came to the assistance of the British with only a few hundred men, yet with such effect that the Picts and Scots were almost immediately defeated. While it is now generally admitted that the names of these chieftains are probably mythical, the fact that many Saxon settlers landed at this time in Britain, and the account of the general events which followed, are unquestionably matters of history. The Picts and Scots were overcome, and the country, already somewhat cultivated and with much of the luxury of a Roman province, soon aroused the cupidity of the strangers. They sent for large reinforcements of their countrymen, and turned their arms against the inhabitants. From this time Saxons constantly poured into the island, and by gradual steps, which it is now impossible to trace, the native Britons were completely subjugated by the new people, who overspread the whole country, introduced their laws, customs, and language, and became the acknowledged founders of most of its future institutions. As successive bands arrived, they landed on different parts of the coast, and their leaders founded separate states. Turner gives an elaborate chronology of these, fixing the date of the establishment of each, and the name of its founder; but later investigations have shown upon how doubtful a basis these accounts must rest. The little that is actually known of the events of the century following the landing of the first Saxon settlers may be said to be the one fact that at different times during that period new detachments of the invaders, with their chiefs, founded eight kingdoms, as follows, mentioning them in their most probable chronological order: Kent, Sussex, Wessex, East Anglia, Mercia, Essex, Bernicia, and Deira, the last two afterward joined in Northumbria. Gradually, during the 8th century, these became united in the alliance called the Saxon heptarchy—though it should properly be called the octarchy; and finally, about 827, they were united into one kingdom, called Anglia, or England (A. S. *Engla-land*), by King Egbert of Wessex. The history of the eight separate sovereignties until this final union presents in general only a series of wars between them, of oppression of the conquered Britons, who revolted again and again, and of such changes in the boundaries of the various kingdoms as render it almost impossible for us to correctly define their limits at any one point of time. The progress of the Saxons after their union under Egbert belongs to the history of England; but their customs, and those laws and institutions which grew up under the heptarchy and under Egbert and his successors, can best be treated here.—At the head of each of the

governments of the heptarchy, and at the head of the whole nation after its union under Egbert, stood the king (*cynig*). He was first chosen from among the leaders of the people, but afterward the office became in some sense hereditary, though not according to the modern laws of succession; for although the new king must be chosen from the descendants or immediate relatives of the late ruler, a younger son was often preferred to the eldest, or a brother's family to the direct heirs, the choice in fact depending greatly on personal qualifications. The king's power was at first decidedly limited by the witenagemote, or supreme council (parliament); but afterward it became more nearly absolute. He determined the rank of his immediate followers, summoned the witenagemote, led in war, &c. The queen (*cecen*) was held in great respect; offences against her were punished like those against the king; and she often played a conspicuous part in the government. Next in rank were the *æthelings* or nobility; and this term included in early times only the immediate family and near relatives of the king. Just below the *ætheling*, and in time coming to share many of his privileges, was the *ealdorman*. Officials of many kinds bore this title, but it was at first generally applied to the governor of a province, who led its forces in war and superintended its affairs in peace. The title was not in early times hereditary, but became so after the reign of Alfred. The *thanes* (*thegnas*) composed the next class, and were landholders, forming a "nobility by service," as it is called by Lappenberg, divided, according to position and immediate attachment, into king's thanes and subordinate thanes. Upon the possession of a certain amount of landed property depended generally their title; though merchants who had made three voyages of a certain length were also entitled to the rank of thanes. The thanes were exactly similar to the barons after the Norman conquest. Below these classes were the common freemen or churls (*ceorlas*), rarely entirely independent men, but generally standing in the relation of retainer to some chief. The lowest class of all was that of the *theowas* or slaves, made up of those prisoners of war who had been reduced to servitude, of the descendants of Roman slaves, and of those made servile as a punishment for crime. These could not be sold outside the country, and in general seem to have been nearly as well off, save in civic rights, as the poorer churls. The chiefs of the Christian clergy occupied high positions, the archbishop holding the privileges and rank of an *ætheling*, the bishop that of an *ealdorman*. They were also prominent members of the witenagemote.—The country of the Saxons was divided into shires, each composed of a certain number (varying greatly in different cases) of hundreds; and these in their turn were made up of those districts which united in choosing (originally) 100 men for the defence of the shire and its

governor. "The meeting of the hundred," says Lappenberg, "was held monthly for objects of voluntary and contentious jurisdiction. The presiding officer was the ealdorman, assisted by the bishop of the diocese and the principal thanes. The townships were represented by their reeves [sheriffs] and four deputies." In northern England a similar division was called a wapentake. A titling was an association of freemen, who bound themselves to become surety for one another in case of misbehavior, and to aid in bringing to trial any one of their number who should commit a criminal offence. Every freeman was obliged by law to enroll himself in such an association.—Among the most cherished Anglo-Saxon institutions was also the *folcmote*. Authorities disagree somewhat as to the nature and privileges of the assemblies thus named, but the term seems to have been freely applied to large gatherings of freemen for counsel on public measures, rather than to any organized convention of the people. The right of meeting in folcmote seems to have corresponded exactly to the modern right of assembling in public gatherings, and of free debate.—See Palgrave's "Rise and Progress of England under the Anglo-Saxons" (London, 1832); Lappenberg's "History of England under the Anglo-Saxon Kings" (English translation by B. Thorpe, London, 1845); "Six Old English Chronicles," edited by J. A. Giles (London, 1848); J. M. Kemble's "Saxons in England" (London, 1849); Sharon Turner's "History of the Anglo-Saxons" (7th ed., London, 1852); "The Anglo-Saxon Chronicle," edited with a translation by B. Thorpe (London, 1861).—**Anglo-Saxon Church.** The Teutonic invaders of Britain, after the fall of the Roman empire of the West, were of course pagans, and, with the pride of a conquering presence of a conquered race, would not receive Christianity from the Welsh Christians. Pope Gregory the Great sent a solemn embassy of 40 Benedictines to Ethelbert, king of Kent, who had espoused Bertha, a Frankish princess. St. Augustin, known as the apostle of the English, was at the head of it. The king consented to be baptized in 597, and Augustin was appointed archbishop of Canterbury. From Kent Christianity rapidly spread among the other Anglo-Saxon kingdoms. In 664 a union of all the churches in Britain was made by the exertions of Theodore, afterward archbishop of Canterbury, and in 668 the services of the church were made uniform over the island. Under Theodore there were an archbishop of York and 15 bishops. During the 8th and 9th centuries the Anglo-Saxon church enjoyed a degree of independence which was not quite canonical. By the aid of Dunstan in the latter part of the 10th century, it was brought into more complete harmony with the Roman see. This church produced the venerable Bede, St. Boniface, the apostle of the Germans, and many others who contributed to the cause of learning and the spreading of Christianity among the pa-

gan nations of the north. Its history has been carefully investigated by Soames, author of "The Anglo-Saxon Church" and "The Latin Church during Anglo-Saxon Times," and by Lingard, "Antiquities of the Anglo-Saxon Church."—**Anglo-Saxon Jurisprudence.** The memorials that have come down to us afford but an imperfect view of Anglo-Saxon laws. Codes are spoken of as having been promulgated by several of their kings, but these do not appear to have been a collection of all the laws in force, but rather such regulations as were new or little known, and which supplemented the body of laws contained in the unwritten customs with which the people were familiar. The very idea of a complete code would have been far in advance of the time. Ethelbert, king of Kent, is said to have published laws as early as A. D. 561. The first laws of much note were those of Ina, king of the West Saxons, after which we have the laws of Alfred, Edward his son, Ethelred, and Canute. The general features of all are similar; they are permeated with the prevailing superstition of the period; they consist in the main of regulations of police more or less barbarous in character, intermingled with moral and religious precepts derived from the ecclesiastics who framed them. The laws of Ina thus commenced: "First, we command that God's servants hold the lawful rule; after that we command that the law and doom of the whole folk be thus held," &c.; and among the first of the laws is one that if a slave be put to work on Sunday, he shall be free. The churls and their tenure, which is the origin of the modern copyholds, are referred to. The next important laws are those of Alfred, which became more famous than they deserved through the admirable manner in which they were administered by that monarch. The first attempt at settling an orderly course of procedure in administering justice was in the laws of Edward the Elder. While these prescribed the trial by ordeal in cases where compurgators did not come forward, yet they provided that trial should be by sworn witnesses as much as possible. The laws of Canute were more complete than any which preceded them, and better deserving the name of a code. They begin as follows: "Let God's justice be exalted; and henceforth let every man, both poor and rich, be esteemed worthy of sole-right, and let just doom be doomed to him." They prescribed regular terms of court, regulated weights and measures as well as moneys, and punished counterfeits with the cutting off of hands. A freeman who was not infamous, and had never failed in oath or ordeal, could clear himself with a single oath; but others must furnish compurgators or submit to the ordeal. It has been a common supposition that Edward the Confessor promulgated a code of written laws, but of this there is no sufficient evidence. The Anglo-Saxons after the conquest exhibited a strong attachment to the laws of their last king, and the

conqueror caused a compilation of them to be made; but it contained little of importance, or that would be likely to be thought important by the people beyond a recognition of their right to assemble in full folemete to elect their sheriff and discuss public affairs. The meagre character of the Saxon compilations is accounted for by the fact that the great body of their law, like that of the English law to this day, consisted of unwritten customs and usages with which the people were familiar, and which the conqueror did not attempt to set aside. Many of these customs, as well as the divisions of the country for administrative and judicial purposes, were of Roman origin. Justice was administered in local courts, of which the chief were the *hundredgemote* or *wapentake*, held by the sheriff and bishop for the trial of criminal causes in every hundred—the sheriff presiding assisted by the bishop on the trial of offences in general, and the bishop with the assistance of the sheriff when offenders against the church were to be dealt with; and the *scyregemote* or county court, which was the principal court of civil jurisdiction, and whose judges were the freemen and landholders of the county, presided over by the earl or sheriff, assisted by the bishop. The Saxons appear to have accepted the idea that the king was the fountain of justice, but his intervention was not often invoked except to set the courts in motion when justice was delayed or refused. From the rude trials by witnesses in their popular tribunals was developed at length the orderly system of trial by jury. The “Mirror of Justice” enumerates several judges who were hanged in Alfred’s reign for causing prisoners to be executed who were not convicted by the unanimous verdict of twelve sworn men. The most remarkable feature of Anglo-Saxon criminal law was the scale of compensation prescribed for the commission of homicide and other crimes. Even the life of the king was rated at a money value, which under the laws of Athelstan was 30,000 thrymsæ, each thrymsæ being worth four pence; while that of an earl was 15,000, and so on down to a common person, rated at only 267. The ears, the teeth, the limbs had each their separate value, and the place where an offence was committed was sometimes an aggravation requiring an additional penalty. The compensation or *were* was payable to the injured person, or, in cases of homicide, to the immediate family of the deceased, or, if he had none, to his other relations. If the offender was unable to pay, he was liable to death, but was allowed to submit to the loss of limb or other corporal infliction instead. Torture to extract evidence was unknown among the Anglo-Saxons. Immunity seems to have been extended in some cases to those who in the heat of passion excited by the chase of an offender should slay him upon the spot, while the irregular infliction of punishment in cold blood upon a detected criminal was visited

with extreme penalties. An offender fleeing to sanctuary was allowed protection during his stay there, whatever his crime might have been. Lands among this people appear to have been held by a species of feudal tenure, and were descendible to all the sons, or, as some writers think, to all the children equally, and they were conveyed either by writing or by ceremonies conducted in the presence of witnesses, designed to give publicity to the transfer. A collection of the laws of the Saxon kings was made by Lambard in the time of Queen Elizabeth, under the title of *Archæionomia*, which was afterward republished by Dr. Wilkins, and also more recently under the title of “Anglo-Saxon Laws and Institutes,” edited by Benjamin Thorpe (London, 1840).

ANGLO-SAXONS, Language and Literature of the. The language of the German tribes who conquered and peopled Britain in the 5th and 6th centuries was by them called Anglisc, Englisc (English); but since English has become so widely different from its mother speech, the name Anglo-Saxon has come into use for the old language. This language was a growth on the island of Britain from the collision of many dialects spoken by the invading tribes. The Celts used a very different kind of speech, so that the Celtic affected the Anglo-Saxon as the tongues of the aborigines of America have affected our English; it gave a good many geographical names, and but few other words. The new language was shaped to literary use by ecclesiastics who wrote and spoke Latin, and a large part of the literature is translated or imitated from Latin works. Hence it contains many words from Latin and frequent imitations of Latin idiom, and it attained the power to render Latin with more accuracy and ease than any other Germanic tongue of its time. The Danes also contributed something to it, especially to the Northumbrian dialect. But it is after all a true Low German speech, closely akin to Frisic, Old Saxon, Dutch, and Platt-Deutsch. The talk in the harbors of Antwerp, Bremen, and Hamburg is said to be often mistaken by English sailors for corrupt English. These Low German tongues are akin to the High German on one side and to the Scandinavian on the other, and these all with the Mæso-Gothic constitute the Teutonic class of languages, which belongs, with the Latin, Greek, Slavic, Sanskrit, and the like, to the Indo-European. The invading tribes had writing of their own in characters called runes, but the literary remains are almost all in an alphabet known as the Anglo-Saxon, the letters of which, except three, are Roman characters, with some fanciful variations. Thorn (þ) and wén (ƿ) are runes, and edh (ð) a crossed *d*. Occasionally k, q, v, z get into the manuscripts, mostly in foreign words, and uu or u for þ. The Semi-Saxon has a peculiar character for j (ȝ). The vowels were pronounced nearly as they now are in German: *a* as in *far*; *á* as in *fall*;

Y	y	Y ypsilon

æ as a in *glad*; æ as a in *dare*; e as in *let*; ê as in *they*; î as in *dim*; ï as ee in *deem*; o as in *wholly*; ô as in *holy*; u as in *full*; û as oo in *fool*; y nearly like u in *music* or the French *u*; ŷ the same sound prolonged. The consonants were pronounced as in English, except that *c* was always like *k*, *g* as in *give*, and both letters were distinctly sounded in initial *hl*, *hr*, *hw*, *wl*, *wr*, *en*. The changes to the modern English sounds have most of them occurred since the time of Chaucer, many since Shakespeare. There are many words common to Anglo-Saxon, Gothic, and Latin, Greek, or Sanskrit. When we compare the spelling of such words, we find that the Anglo-Saxon retains the original vowels better than the Gothic. It has the old *â*, *ê*, while the Gothic has changed to *ô* or *é*; and the old *î*, while the Gothic has *ei*. In its consonant system it agrees with the Gothic, and is midway between the old forms of the Greek, or Latin, and High German. Each surd mute of the Greek or Latin is in Anglo-Saxon changed into its cognate aspirate: *t* to *th*, Latin *tu*, A. S. *thû*, thou; *p* to *ph=f*, Lat. *ped-es*, A. S. *fēt*, feet; *c* to *ch=h*, Lat. *cannab-is*, A. S. *henep*, hemp. Each sonant mute changes into its cognate surd: *d* to *t*, Lat. *dent-es*, A. S. *têth*, teeth; *b* to *p*, Lat. *cannab-is*, A. S. *henep*, hemp; *g* to *c*, Lat. *eg-o*, A. S. *ie*, I. Each aspirate mute changed to sonant: *th* to *d*, Gr. *thēr*, A. S. *deôr*, deer; *ph=f* to *b*, Lat. *frater*, A. S. *brôther*, brother; *ch=h* to *g*, Lat.

homo, A. S. *guma*, man. These changes were complete in the 3d century, and here the Anglo-Saxon has remained, while the High German has shifted in the same way a second time, changing *ie*, I, to *ich*; *thû*, thou, to *du*; *deôr*, deer, to *thier*, and the like; so that Anglo-Saxon stands in the same relation to German that Sanskrit, Greek, and Latin do to Anglo-Saxon. A marked fact in this speech is the sensitiveness of the vowels to the influence of other letters. A stem *a* may appear as *a*, *ea*, *e*, or *o*, according to the vowel or consonant after it; and so with other letters. In cases where *i* follows the stem, *man* changes to *men*; so *fôt* to *fêt*, feet; *gôs* to *gês*, geese; *mûs* to *mÿs*, mice, and the like. Such changes are called *umlaut*. Breaking is produced by a consonant, as when *e* or *g* changes *a* to *ea*: Lat. *castrum* to *ceaster*; or *l* or *r* changes a preceding *i* to *eo*: *meole*, milk.—There are inflection endings for five cases, three numbers, and three genders; but the instrumental case is rare, and the dual number is found only in pronouns. The substantive has four declensions distinguished by the endings of the genitive singular—*es*, *e*, *a*, *an*. The three first come from old vowel stems, the last from a consonant stem.

FIRST DECLENSION.

SINGULAR.	An. Saz.	English.	German.	Latin.
Nominative,	wulf,	wolf,	wolf,	anser.
Genitive,	wulfes,	wolf's,	wolfes,	ansersis.
Dative,	wulfæ,	to or for a	wolfæ,	anseri.
		wolf,		
Accusative,	wulf,	wolf,	wolf,	anserem.
Instrumental,	wulfæ,	by or with a	—(ablative)	ansere.
		wolf,		
PLURAL.				
Nominative,	wulfas,	wolves,	wölfe,	anseres.
Genitive,	wulfâ,	of wolves,	wölfe,	anserum.
Dative,	wulfum,	to or for	wölfen,	anserbis.
		wolves,		
Accusative,	wulfas,	wolves,	wölfe,	anseres.
Instrumental,	wulfum,	by or with	—(ablative)	anserbis.
		wolves,		

FOURTH DECLENSION.

SINGULAR.	An. Saz.	English.	German.
Nominative,	oxa,	ox,	ochse.
Genitive,	wulfâ,	of an ox,	ochsen.
Dative,	oxan,	to or for an ox,	ochsen.
Accusative,	oxan,	ox,	ochsen.
PLURAL.			
Nom. and Acc.	oxan,	oxen,	ochsen.
Genitive,	oxenâ,	of oxen,	ochsen.
Dative,	oxum,	to or for oxen,	ochsen.

The common English endings of the possessive and plural are from the first declension. The *-en* of *oxen* is from the fourth. Neuters have no plural sign, and so some English words from them do not yet always use it: *sheep*, *deer*, *swine*, *folk*, *hair*, *head*, *hundred*, *year*, and the like. The old feminines were declined somewhat like the Latin first, with a genitive in *-e*, and we find a few examples of it in Chaucer. Gender is determined by the endings of words; it agrees generally with the German: *wif-man*, woman, is regularly masculine because it ends in *man*; *wif* wife, is neuter; *sunne*, sun, is feminine; *môna*, moon, is masculine. Each adjective may be declined in two ways according as it is definite or indefinite, as in German.

An ending *-e* is found in Chaucer to indicate sometimes the plural, sometimes the definite declension. Comparison in Anglo-Saxon was by endings, *-r, -st*; not by *more* and *most*.

THE PERSONAL PRONOUNS.

	SINGULAR.	PLURAL.	DUAL.	
Nom.	ic, <i>I</i> .	wē, <i>we</i> .	wit, <i>we two</i> .

Nom.	he.	heō, <i>she</i> .	hit, <i>it</i> .	hi, <i>they</i> .
Gen.	his.	hire, <i>her</i> .	his, <i>its</i> .	hira, <i>their</i> .
Dat.	him.	hire, <i>her</i> .	him, <i>it</i> .	hem, <i>them</i> .
Acc.	hine.	heō, <i>her</i> .	hit, <i>it</i> .	hi, <i>them</i> .

The English *she, they, their, them*, are from the Anglo-Saxon demonstrative *sc, seō, that*; *its* is a modern growth, not found in the first edition of our English Bible. The articles are both in use, and the demonstratives *that, that*, and *thes, this*, plural *thás, those*; the personals are used as reflexives; *hwá, who*, is an interrogative; other English pronouns are from Anglo-Saxon originals. So are the numerals except second, A. S. *other*.—There are two great classes of verbs: 1, the ancient or strong class, which formed their past tense by reduplication, repetition of their root; 2, the modern or weak class, which formed their past tense by composition with *dide, did*. In the first class there are five conjugations, distinguished by the vowel of the past tense. 1. The original root is *a*, unchanged in the past: *swimman, swam, swimmen, swim, swam, swum*. 2. The root is *i*, changed to *á* in the past: *ridan, rād, riden, ride, rode, ridden*. 3. The root is *u*, changed to *eá, a*, past *eá: cleofian, cleáf, clofen, cleave, clove, cloven*. 4. The root was *á*, changed to *u*, past *ó: wacan, wóc, wacen, wake, woke, waken*. 5. The root a diphthong or long vowel changed to *eó, é: feallan, feól, feullen, fall, fell, fallen*. The weak verbs make another conjugation: 6. The past a compound with *dide, -de: lufian, lufjode, lufjód, love, loved, loved*. The *umlaut* and breaking referred to in the first part of this article introduce variations of vowel in different parts of the same verb, and different variations for different verbs, so that to a superficial view there may appear to be many conjugations, or no regularity at all. The following paradigms show the inflection endings:

	INDICATIVE MODE.	
Present and future tense.	Past, strong.	Past, weak.
1, nime, <i>take</i> .	nam, <i>took</i> .	lufjode, <i>loved</i> .
2, nimest, <i>takest</i> .	nám, <i>tookest</i> .	lufjodest, <i>lovest</i> .
3, nimeþ, <i>takeþ</i> .	nam, <i>took</i> .	lufjode, <i>loved</i> .
1, 2, 3, nimath, <i>take</i> .	námon, <i>took</i> .	lufjodon, <i>loved</i> .
	SUBJUNCTIVE MODE.	
	Present.	Past.
Singular,	1, 2, 3, nime.	nám.
Plural,	1, 2, 3, nimem.	námen.
	Imperative.	Infinitive.
Singular, nim.		niman.
Plural, nimath.		Gerund, tō nimenþ

PARTICIPLES.

Present, nimenð, *taking*.
Passive, nimen, *taken*; gelufjod, *loved*.

The *-th* of the indicative 3d singular and the plural appears as *-s* in the northern dialect of Anglo-Saxon. There are said to be 168 plurals in *-s* and 46 in *-th* in the Shakespearean folio of 1623. (Prof. T. R. Lounsbury, "On Certain Forms of the English Verb," in "Transactions of the American Philological Association," 1869-'70.) The subjunctive is used for our potential and imperative, as in the English expressions, "it were a s'm," "be it so"; but a periphrastic potential in *may, can, might, &c.*, is in use. The gerund in *-enne* changed to *-ende* and then to *-ing*; and in the English we have in the ending *-ing* a verbal noun, present participle, and gerund mixed. The form given above as the present tense may be used for any modification of both present and future act, the other form to express every shade of past act; but auxiliaries are also used. A perfect in *habbe, have*, and a pluperfect in *hæfje, had*, are in full use, though the participle of the principal verb is often in the accusative case agreeing with the object of *habbe: hē hæfþ mon geworhtne, he has man wrought*. A few intransitives use *com (am)* and *was (was)* for perfect signs: *hē is gecumen, he is come; hē was ágán, he was (=had) gone*. *Scal, shall*, and *wille, will*, are common for future signs, though they generally have some meaning of duty, power, promise, resolve, in addition to that of future time. A progressive form is common in the active: *is feohtende, is fighting, continues fighting*; but not in the passive. The emphatic form in *do* hardly occurs. The adverbs, prepositions, conjunctions, and other particles are many of them common to other Indo-European tongues, and many of the more obscure may be traced to pronouns. Composition is more freely used in Anglo-Saxon than in English, and many of the suffixes and prefixes are there found as separate words.—A body of rules almost as great as those used in Latin grammar is needed to state the uses of the different cases. Some verbs govern a genitive, some a dative or instrumental, some the accusative, some two or three different cases. The uses of the subjunctive mode are various and obscure. The arrangement of the parts of a sentence is often intricate. The syntax is that of a highly inflected language. Most of the difficulties of English idiom are to be traced to Anglo-Saxon combinations, and they are often easily understood by the help of the old meanings of the words, or the old inflection forms.—For the study of the language may be used Bosworth, "Anglo-Saxon Dictionary" (London, 1848); Marsh, "English Language and its Early Literature" (New York, 1862); Hadley, "Brief History of the English Language," in Webster's Dictionary (1865); Rask's grammar, translated by Thorpe (London, 1865); Shute, "Manual of Anglo-Saxon for Beginners" (New York, 1867); March, "Compara-

tive Grammar of the Anglo-Saxon," and "Introduction to the Study of Anglo-Saxon" (New York, 1870); Corson, "Handbook of Anglo-Saxon and Early English" (New York, 1871); Grimm, *Deutsche Grammatik* (Göttingen, 1840); Ettmüller, *Lexicon cum Synopsi Grammatica* (Quedlinburg and Leipsic, 1851); Heyne, *Kurtz Laut- und Flexionslehre* (Paderborn, 1862); Koch, *Historische Grammatik der englischen Sprache* (Weimar, 1863); Grein, *Sprachschatz der Angelsächsischen Dichter* (Cassel and Göttingen, 1864); Maetzner, *Englische Grammatik* (Berlin, 1865).—**Anglo-Saxon Literature.** It was a habit of the early Germans to give high honor to the *scōp* or poet, and long before their conquest of Britain there were current among their cycles of songs, of mythological and heroic ballads, such as furnish the material for epic poems. Their exploits in Britain doubtless added to the number of current ballads, and of skilful poets and singers. We learn from Beda that the harp passed from hand to hand at feasts, and that it was disgraceful for any man not to be able to sing in turn. Bishop Aldhelm used to stand in minstrel's garb on the bridge over which the people were to pass and collect a crowd by the beauty of his song, into which, when their attention was gained, he wove words of devotion. The verse common to the northern nations was brought to great perfection among the Anglo-Saxons. It is an accentual rhythm, marked off into verses by alliteration. The common narrative verse is constructed in sections separated by a metrical pause. Each section has regularly four accents. This accent or metrical stress falls on each syllable having a primary accent in prose, on many syllables having a secondary accent, and in certain metrical emergencies on other syllables, especially the last syllable in each section. Each metrical stress is followed by a remission of voice, which may be silent, or filled by an unaccented syllable or two. Each perfect line contains three alliterating words, two in the first section, and one in the first part of the second section.

<i>Cyning sceal mid eadwe</i>	<i>ewene gebidgan,</i>
<i>binnum and beorgan:</i>	<i>bu' sceoton a'rest</i>
<i>geofum god' wesian.</i>	
A king shall with cattle	a queen buy,
with heakers and bracelets:	both should first
in girts good be.	(Gnom. Exon., line 82+.)

Many lines have but one alliterating word in the first section, and irregular sections have three or sometimes only two feet. Rhyme is found occasionally in most poems. A few contain rhyming passages of some length. One is known as the rime song. It contains 87 verses in all sorts of rimes, and is plainly a task poem to show riming skill.

<i>flōw' mōk' fl' teth</i>	<i>flān' mōn' hō' teth,</i>
<i>bowg-song' b' teth:</i>	<i>bād' ad' thar' teth, &c.</i>
<i>scyfdan' bisece' redē</i>	<i>scyfdan' gēne' edē</i>
<i>wōn' mōn' bise' redē</i>	<i>wōl' drē' gēhe' edē, &c.</i>
Subtle fiend fighteth,	darts sin wheteth,
borrow-sorrow biteth,	hold old severeth, &c.
From sins freed	let us escape saved
from stains covered,	gloric—sly honored, &c.

Almost all the Anglo-Saxon poetry we have is in this verse, varied occasionally by passages in longer verses of similar construction. It is the common verse in Old Saxon, and in Icelandic has been cultivated into a surprising variety of artificial meters. The poems remaining in Anglo-Saxon are few. The Christians destroyed whatever was tainted with paganism, and the Normans neglected everything Anglo-Saxon. They have been divided into seven classes. 1. *The ballad epic.* Of this we have one poem and a few fragments. "Beowulf" is a poem of 3,183 lines, celebrating the exploits of a Gothic prince Beowulf, for the most part in slaying monsters. The scene is laid in the island of Seeland and the opposite Gothland. It is evidently a pagan production, though rewritten by a Christian. Only one copy of it is known, and no mention of it has been found elsewhere. A few names and facts referred to in it have however been identified in old German history, and serve to show that it embodies historical matter of the end of the 5th century. The manuscript is thought to be of the 10th century. Its existence is mentioned in Wanley's catalogue, 1705. In 1731 it was badly injured by fire. In 1786 the Dane Thorkelin had two copies of it made, and in 1815 published an edition. No particular notice was taken of it till the late revival of Anglo-Saxon scholarship; but the present generation of Anglo-Saxon scholars, especially in Germany, have studied it with great enthusiasm, and find in it the Iliad and Odyssey of the north. Among many editions, translations, and essays of elucidation and criticism, we mention Kemble, edition (London, 1833) and translation and glossary (1837); Ettmüller, translation and valuable notes and introduction (Zürich, 1840); Thorpe, text, translation, and glossary (Oxford, 1855); Grein, two editions (Göttingen, 1857 and 1867), and translation (1857); Gruntvig, text and notes (Copenhagen, 1861); Heyne, two editions with notes and glossary (Paderborn, 1863, 1868), and translation (1863); Wackerbarth, translation into rhymed English verses like Scott's "Marnion" (London, 1849); Haigh, "The Anglo-Saxon Sagas," containing a notable attempt to locate Beowulf on English ground (London, 1861); Morley, "English Writers," vol. i. (London, 1867). A few fragments may be classed with "Beowulf," as "The Traveller's Song," 143 lines; "The Fight at Finnsburg," 48 lines; "Bryhtnoth," 325 lines; the first two to be found in Thorpe and Kemble, and all in Grein (1857). 2. *The Bible epic.* This is a growth of Christian England. We have the story of its originator, Caedmon, from Beda, who lived near him, and may have seen him. He was an unlearned man, so backward that he could not take his turn in singing to the harp at feasts, and so sensitive that he would leave the board in shame as the harp came round. Once when he had done this, and fallen asleep in a stall near by, a vision appeared to him, and bade

him sing. "I cannot sing," said he; "I have left the feast and come here because I cannot sing." "Sing for me though," said the vision; "sing the creation." And he sang the famous verses which were to usher in a new era of song:

Nu seylon Æergan	the	Æaenricæas	nard,
met.ades mæcti	and	his	moldigane,
were unaldur fadur:	sae	he	unundra gihuæas
eel dryctin	or	astellide.	
He werist scep	a	ella	barnum
Æeben til Æarofe.	Æaleg	scepen:	
tha middungeard	on	cynnaes	nard
eal dryctin,	æfter	tlada.	
firum, foldan,	fræa	allmeetic.	

"Now must we glorify	the	guardian	of	heaven's	kingdom,					
the	maker's	might,	and	his	mind's	thought,				
the	work	of	the	worshipped	when	of	his	wonders	each	other
the	ever	living	lord	ordered	the	origin,				
He	erst	creat'ed	for	e	arth's	children				
Heaven	as	a	high	roof,	the	holly	creator:			
then	this	mid	world	did	man's	guardian				
the	ever	living	lord	afterward	prepare,					
for	men	a	mansion,	the	master	almighty."				
					(Hadley's	translation.)				

Next morning he told his story and repeated the verses. The abbess Hild and her learned men proved him, and found that he could turn into noble poetry passages from the Bible which they read to him. They recognized the gift as divine, and received him into the monastery. There he led a holy life, humble and lovely, and composed many Christian poems. Hosts of imitators followed. The "Hælland," a poem of some 6,000 lines in Old Saxon, celebrating the acts of the Saviour, is thought by many to be a translation from Cædmon. But none equalled him till Milton. A single manuscript remains, containing Genesis (2,935 lines), Exodus (589), Daniel (765), Christ and Satan (733). All that is known of it is that it belonged to Archbishop Usher, who gave it to Junius, who printed it at Amsterdam in 1635, and who bequeathed it to the Bodleian library. There is no external evidence to prove these poems Cædmon's, but they have been accepted provisionally by most students as a rewriting of his originals in another dialect. The Genesis gives the story of man's first disobedience and his fall, beginning with the fallen angels. The description of Satan, his first speech, some striking expressions in the description of his fall, of heaven, hell, Adam and Eve, strongly suggest that Milton borrowed from Cædmon, but they may be accounted for by their using common sources. Editions are by Thorpe, for the society of antiquaries (London, 1832; Illuminations, 1833), Grein (Göttingen, 1857, translation, 1857), and Bouterwek (text, translation, copious introductory essays, notes, and lexicon, Güttersloh, 1854). Among the many valuable articles upon it may be mentioned Dietrich's in Haupt's *Zeitschrift*, X., 310-367. With these works of Cædmon may be classed a fragment of Judith (350 lines), Cynewulf's "Christ" (1,694), "The Harrowing of Hell" (137), and some other fragments, all to be found in Grein's *Bibliothek der Angelsächsischen Poesie* (Göttingen, 1857), and translations in his *Dichtungen der Angelsachsen* (1857). 3. *Ecclesiastic*

narratives—the lives of saints, and versified chronicles, without the epic exaltation of the former classes. Such are "Andreas" (1,724 lines), "Elene" (1,321), "Juliana" (731), and "Guthlac" (1,353). 4. *Psalms and hymns*—translations of Hebrew psalms and a few Christian hymns and prayers. The version of the Psalms has been attributed to Bishop Aldhelm, (656-709). The manuscript is in the royal library at Paris. Editions have been published by Thorpe and Grein; Essays by Dietrich in Haupt's *Zeitschrift* (IX., 214-222). 5. *Secular lyrics*. A few, mostly elegiac, are found in the Anglo-Saxon Chronicle, celebrating kings and heroes. They are also to be found in Grein's *Bibliothek*. 6. *Allegories, gnomic verses, riddles*. This was a favorite style of composition with the later Anglo-Saxons. We have in Grein's *Bibliothek* "The Phoenix," a translation from Lactantius, much expanded (677 lines); "The Panther" (74); "The Whale" (89); also gnomic verses which are still interesting, and riddles in considerable numbers, and hard enough to guess. 7. *Didactic ethical*. The "Meters of Boëthius" are versifications of passages in Boëthius *De Consolatione Philosophiæ*, attributed to King Alfred. They were transcribed by Junius from a manuscript since lost. Editions are by Rawlinson (Oxford, 1698); Fox, with translation (London, 1835); Grein (1858); and Fox, (2d ed., with metrical rendering by Martin Farquhar Tupper (London, 1864).—The Anglo-Saxon prose is of comparatively little literary value. It affords abundant material for the study of the language and the people, but consists mostly of translations from the Latin. They have been classified as follows: 1. *Theological*—translations of the Bible. Portions of Genesis, Exodus, Leviticus, Numbers, Deuteronomy, Joshua, and Judges, called the Heptateuch, together with an outline of Job, the Gospel of Nicodemus, and a fragment of Judith, were published by Thwaites (Oxford, 1698). The Psalms are spoken of above. We have several manuscripts of the Gospels. Editions have been published in England by Parker (1571), Marshall (1665), Thorpe (1842), and Bosworth (with the Gothic, Wyckliffe, and Tyndale versions in parallel columns, London, 1865). Kemble began an edition with the old Latin and four Anglo-Saxon texts printed together, and various readings from four others. Matthew has been printed in this form, and the work is going on at the University press, Cambridge. A large number of homilies are still to be found. A set by Ælfrie, 80 in number, compiled or translated from Latin works, about A. D. 990, for the unlearned, were printed by Thorpe for the Ælfrie society (1844-'6). More are promised by the early English text society. 2. *Philosophy*. In this department we have only Alfred's translation of Boëthius, mentioned above. 3. *History*. The Anglo-Saxon Chronicle extends from the invasion of Julius Cæsar to Henry II., 1154. As far as the history of Beda extends, it is

abridged from it or from some common source. It has been supposed that Alfred had it compiled and copies placed in the monasteries. How the records were kept afterward is not known. It is for the most part a meagre note of events of little interest, but in the later times there are sometimes reflections and poetical passages, as well as sketches of character. It has been often printed and translated. Thorpe's edition (London, 1861) has seven parallel texts, a translation, and indexes. There are also a large number of charters, deeds, wills, and similar documents remaining, of which Kemble has published six volumes (*Coder Diplomaticus Ævi Saxonici*, London, 1839-46). Bede's "Ecclesiastical History" was written by him in Latin, and translated into Anglo-Saxon by Alfred. It is one of the world's great books. It has passed through many editions in many countries. Wheloc's edition has Latin and Anglo-Saxon in parallel columns (Cambridge, 1644); and Smith's has various readings (Cambridge, 1722). A new edition is needed. For ancient history there is Alfred's translation of Orosius, with additions by the translator of some value. Thorpe's edition with translation and glossary is in Bohn's library (London, 1857). There are some biographies. St. Guthlac has been repeatedly printed (Goodwin, London, 1848). 4. *Law*. A large body of laws remains, extending from Ethelbert, who was king of Kent at the time of its conversion to Christianity, to those of William the Conqueror. The best editions are those of Thorpe (London, 1840), containing the ecclesiastical institutes, and Schmid (Leipsic, 1858), a critical text with Latin and German translations, notes, and a glossary. These and the charters are perhaps the most valuable prose remaining for the study of the people. 5. *Natural science and medicine*. "Popular Treatises of Science" (Thorpe, London, 1841): "Leechdoms" (3 vols., O. Cockayne, London, 1864-'6). 6. *Grammar*. Ælfrie has a Latin grammar in Anglo-Saxon, which answers as a reverse grammar. It is printed in Somner's Dictionary (Oxford, 1659). Ælfrie's "Colloquy," in Thorpe's "Analecta Anglo-Saxonica" (London, 1846). There are a few glossaries in Wright (London, 1857).

ANGOLA, in its wider sense, a Portuguese colony on the W. coast of South Africa, Lower Guinea, between lat. 7° 30' and 17° S. It was discovered by the Portuguese in 1488, and they have ever since held it, except from 1641 to 1648, when the capital and a portion of the colony were occupied by the Dutch. The government general of Angola, as claimed by the Portuguese, embraces an area of upward of 200,000 sq. m. The population is estimated by the Portuguese government at 2,000,000. The colony is divided into four districts, besides the Gimbandi country, which is likewise regarded as belonging to it: Ambriz, Angola proper, Benguela, and Mossamedes. The rule of the Portuguese is recognized between the

Koanza and the Dande only, the main part of Angola proper; outside of this territory they have isolated fortified places, and the native chiefs sustain the relation of more or less doubtful vassals. A line of forts which they intended to construct across the continent to connect with their colony of Mozambique in eastern Africa has never been completed, but the country in the interior has been explored to some extent. The soil is very fertile, and the vegetation is luxuriant; the fauna and flora are tropical. Along the rivers sugar cane is raised, and in the primitive forests excellent coffee is found. The climate is unhealthy along the coast. The mountains contain gold, iron, lead, and sulphur. Spring, the rainy season, begins in September. The most intelligent among the natives are the people of the district of Ambaca, most of whom are able to read and write. As roads are almost wholly wanting, the government employs *carregadores* (burden-carriers), who are furnished by the villages. In the district of Golungo-Alto the number of these carriers was estimated by Dr. Livingstone at 6,000. An army of 5,000 men, four war vessels, and the packet service consume nearly the entire revenue of the colony. A Catholic bishop was appointed for Angola about the middle of the 16th century, and a large number of the natives were nominally received into the church; but since the expulsion of the Jesuits, the native churches have been to a large extent without priests, and the population has partly relapsed into paganism. In 1857 there were in the whole diocese only six priests, though the Christian population was estimated at 300,000.—The capital, Saint Paul de Loanda, on the coast of Angola proper, is the seat of the governor general and of the bishop; pop. 12,500, of whom 850 are whites, 2,500 mulattoes, and the remainder negroes. The chief coast towns of the three other districts are Ambriz, São Felipe de Benguela, and Mossamedes. (See GUINEA.)

ANGORA (Turk. *Engurich*; anc. *Ancyra*), a city of Asia Minor, capital of a Turkish eyalet of the same name, 220 m. E. S. E. of Constantinople; pop. about 45,000, including about 30,000 Turks, 10,000 Armenians, 4,000 Greeks, and 1,000 Jews. It is situated in the midst of a vast elevated plain, abounding in fruits and pasturage, over which the roving tribes of the Turcomans tend their sheep, goats, and horses. The citadel is situated on a steep rock, and its walls are covered with inscriptions. The trade with the west is chiefly in the hands of the Greeks and Armenians, and thus the city in social life is rather European than Mohammedan. It is the see of a Greek and of a Catholic Armenian bishop. On July 20, 1402, Angora was the scene of a terrible battle between Timour and the sultan Bajazet I., in which the latter was captured. There are some ancient remains. (See ANCYRA.)—The Angora goat, with its silken fleece, is the most curious product of this region. Its hair, which is white

and soft, and about eight inches long, is shorn twice a year, and is much esteemed as material for shawls. In 1869 the number of these goats

Angora Goat.

in and near Angora was estimated at 1,000,000. The yearly yield of wool is about 2,700,000 lbs. The Angora goat was introduced into South Carolina in 1849, and still more were imported in 1863.

ANGORNO, a town of Bornoo, in central Africa, near the S. W. shore of Lake Tchad; pop. said to be above 30,000. Weekly markets are held, at which a very extensive trade is carried on in cotton, amber, metals, slaves, &c.

ANGOSTURA, or *Ciudad Bolívar*, a city of Venezuela, capital of the province of Guayana, on the right bank of the river Orinoco, at a pass (*angostura*) where it is confined between high rocks, about 260 m. S. E. of Caracas; pop. about 7,000. It was founded in 1674, and named San Tomas de la Nueva Guayana, to distinguish it from another San Tomas 32 leagues distant. Its name was changed to Ciudad Bolívar, and subsequently in common speech to Angostura. It is built in the form of an amphitheatre, on the slope of a rocky hill, destitute of vegetation. The houses are massively constructed, usually of two stories. The city is the principal emporium for the commerce of the Orinoco, although 240 m. from the mouth of the river. It is the seat of a bishopric, and contains a college, ecclesiastical seminary, hospital, and a hall in which a session of the congress of Colombia, then including New Granada and Venezuela, was held in 1819. The city is defended by a fort on the opposite side of the river, here 3,100 ft. wide. The exports consist of cotton, cocoa, indigo, hides, sugar, and Angostura bark.

ANGOSTURA BARK, the bark of *galipea officinalis*, a South American tree of the rue family, growing on the river Orinoco, and especially on the Caroni, Venezuela. It possesses a peculiar and disagreeable smell when fresh, and a bitter and slightly aromatic taste. It is sometimes used in medicine as an aromatic tonic. By the natives it is employed to intoxicate fish, as the cinchona is in Peru. The false Angostura may be distinguished by its greater thickness and hardness, its total want of odor,

and its intense tenacious bitterness, due to the poisonous alkaloid brucia. When steeped in water it does not become soft like the true Angostura. It is said to be the bark of *strychnos nux-tomica*.

ANGOT, or *Ango, Jean*, a French merchant of Dieppe, died in 1551. He made trading voyages to Africa and the East Indies, and secured a large fortune, which he used with liberality. Some of his ships having been captured by the Portuguese, he fitted out a fleet, fully provided with soldiers and arms, which entered the Tagus and blockaded Lisbon. Every vessel coming to that port was intercepted, while both shores on the river were devastated. The king of Portugal sent an ambassador to Francis I., who referred him to the merchant of Dieppe. Angot, however, persevered, and forced Portugal to pay a large indemnity for his losses. Unsuccessful speculations brought ruin upon him, and the king of France, to whom he had lent large sums, having failed to repay him, Angot spent his last years in destitution.

ANGOULÊME (anc. *Inculisma*, or *Civitas Ecolismensium*), a town of France, capital of the department of Charente and of the ancient province of Angoumois, situated on the Charente, 66 m. N. E. of Bordeaux, on the railway connecting that city with Paris; pop. in 1866, 25,116. It is built on an isolated hill, rising about 200 feet above the river; and though the streets are narrow and crooked, it presents with its white stone houses a neat and cheerful aspect. In the centre of the town is the old ruined castle, the birthplace of Marguerite of Navarre, and remains of the ancient fortifications are also extant. A noble cathedral of the 12th century, the church of St. André dating from the 11th, and a Benedictine abbey of the time of Charlemagne, are among its other antiquities. It has a college, a museum of natural history, manufactures of paper, woollens, linen, earthenware, and cognac, a cannon foundry, and a thriving trade with Bordeaux and the southern departments. It was for some years the seat of a naval school, transferred to Brest in 1830.—From the 9th century Angoulême, with its territory of Angoumois, to which Périgord was at first united, was governed by counts. In 1360 it was ceded to the English, who were driven out in the reign of King Charles V. It afterward belonged to the crown, was erected into a duchy by Francis I., and formed a royal apanage till 1650, since which the title of duke of Angoulême has been only nominal.

ANGOULEME. I. Charles de Valois, duke of, natural son of Charles IX. of France by Marie Touchet, born April 28, 1573, died Sept. 24, 1650. He received from Catharine de' Medici the counties of Auvergne and Lauragais, married the daughter of the constable de Montmorency, distinguished himself at the battles of Arques, Ivry, and Fontaine Française, but was sentenced to perpetual imprisonment for certain intrigues with his uterine sister, the mar-

quise de Verneuil. Released in 1616, he conducted the siege of Soissons the next year, obtained from Louis XIII. the duchy of Angoulême in 1619, and besieged Rochelle in 1628. He took part also in the wars of Languedoc, Germany, and Flanders. He left *Mémoires* of the reigns of Henry III. and Henry IV., a *Relation de l'origine et succès des chérifs, et de l'état des roy-aumes de Maroc, Fez et Tarudant*, translated from the Spanish of Diego de Torres, and some other writings, all of which have been published. **II. Louis Antoine de Bourbon**, duke of, eldest son of Charles X. of France and Marie Thérèse of Savoy, born at Versailles, Aug. 6, 1775, died at Görz, June 3, 1844. At the outbreak of the revolution he accompanied his father (then duke of Artois) to Turin, where he spent a few years in military studies. In 1792 he received a command in Germany, but he was not fitted for a soldier, and soon withdrew from the field, retiring with his father to Holyrood, and subsequently joining his uncle Louis XVIII. at Blankenburg and Mitau. At the latter place he married, June 10, 1799, his cousin Marie Thérèse Charlotte, daughter of Louis XVI. During the hundred days he was appointed lieutenant general of the kingdom, and made a weak attempt to oppose the emperor; but his troops abandoned him, and after a few days' detention as a prisoner he was sent to Barcelona. After the second restoration he was charged with the suppression of disorders in the southern provinces, and in 1823 commanded the army of intervention which put down the revolution in Spain. In July, 1830, he signed with his father the act of abdication in favor of his nephew the duke of Bordeaux (now Count de Chambord), and went into exile with the rest of the royal family. He was a man of mean abilities and sluggish disposition. **III. Marie Thérèse Charlotte**, duchess of, wife of the preceding, and daughter of Louis XVI. and Marie Antoinette, born at Versailles Dec. 19, 1778, died at Frohsdorf, Oct. 19, 1851. She shared the imprisonment of her parents in the Temple, and after their execution was held in captivity till December, 1795, when Austria procured her liberation in exchange for certain members of the convention. She lived at Vienna till her marriage, known by the title of *madame royale*. Afterward she shared the vicissitudes of her husband's exile, sustaining his courage by her superior spirit and intelligence, returning with him to France in 1814, and exerting a great influence over the troops at Bordeaux during the hundred days, so that Napoleon called her "the only man in the family." At the time of the July revolution she was at Dijon, and made a dangerous journey in disguise to Rambouillet, where she rejoined the duke. She went with the royal family to England, where her husband and she assumed the titles of count and countess of Marne. They lived some time at Holyrood, but the climate of Scotland proving too severe for the countess, they removed to the continent.

ANGOUMOIS, one of the old provinces of France, between Poitou and Guienne, bounded W. by Saintonge, with which it was joined to form a military government. Capital, Angoulême. It nearly corresponded to the present department of Charente. It was generally governed by the counts of Angoulême from the 9th to the 14th century, when it was united to the crown.

ANGRA, a seaport town on the S. side of the island of Terceira, one of the Azores; pop. 13,000. It is well built on a hill rising from the water's edge, has wide but dirty streets, and is generally the residence of the governor of the Azores, as well as of the consuls of England, France, and Holland. The harbor is protected by two forts, but, though the best in the Azores, it is exposed to all winds from the S. S. W. by S. to the E., and on the approach of a gale from this quarter vessels are obliged to put to sea for safety. The principal exports are wine and grain.

ANGUSCIOLA, *Angussola*, or *Agnosciola*, *Sofonisba*, an Italian female painter, born at Cremona about 1530, died about 1620. After executing a number of portraits and some fine historical pieces, she went to Madrid in 1561, at the invitation of Philip II., and painted portraits of Queen Isabella and other celebrities of the Spanish court. Constant application brought on blindness in her latter years. Vandyke, who visited her frequently, was wont to speak with great respect of her knowledge of art. Her sisters *LUCIA*, *EUROPA*, and *ANNA MARIA* also painted, but were less distinguished than *Sofonisba*.

ANGUS, *Earls of*. See *Douglas*.

ANHALT, a duchy of the German empire, situated on both banks of the Elbe and the Saale, and bounded by Prussian Saxony, Brandenburg, and Brunswick; area, 897 sq. m.; pop. in 1871, 203,354. It was formerly divided into four duchies, called Anhalt-Dessau, Anhalt-Bernburg, Anhalt-Zerbst, and Anhalt-Köthen, after the principal towns, but was in 1793 united into three, in 1853 into two, and finally in 1863 into one. The soil is mostly level and fertile, and here and there wooded and picturesque. It produces corn, flax, tobacco, hops, and fruits. There are iron, lead, and copper mines. The Anhalt family trace their lineage to Esico von Ballenstedt, who flourished in the 10th century. They have been generally of martial spirit, and in the history of Germany they have furnished various distinguished generals in the service of the emperors and of the kings of Prussia. From Anhalt-Zerbst came Catharine II., empress of Russia. The present duke, Frederick, born April 29, 1831, succeeded his father May 22, 1871. Capital, Dessau.

ANHYDRIDES, compounds which become acids upon the addition of water. In technical language, they are the oxides of acid radicals, and stand in the same relation to acids as the oxide of potassium, K_2O , does to the hydrated potash, KHO . The most familiar anhydrides are sulphuric, nitric, hypochlorous, and acetic; these have long been called anhydrous sulphu-

ric acid, anhydrous nitric acid, anhydrous hypochlorous acid, and anhydrous acetic acid; but as they do not possess acid properties until combined with water, it is now proposed to call them sulphuric anhydride, nitric anhydride, &c. The following formulas will illustrate how an anhydride becomes an acid on the addition of water: SO_3 (sulphuric anhydride) + $\text{H}_2\text{O} = \text{H}_2\text{SO}_4$ (sulphuric acid); N_2O_5 (nitric anhydride) + $\text{H}_2\text{O} = 2\text{HNO}_3$ (nitric acid); Cl_2O (hypochlorous anhydride) + $\text{H}_2\text{O} = 2\text{HClO}$ (hypochlorous acid). Anhydride has therefore a signification of its own, and must not be confounded with the term anhydrous, applied to substances which have no water either mixed or combined with them.

ANI, or **Anni**, a ruined city of Turkish Armenia, on the Arpi Tchah, about 25 m. E. S. E. of Kars. Its ancient name appears to have been Abnieum, but its history is only imperfectly known. In the 5th century it was a small fort; in the 10th it became the capital of the Bagratide kings of Armenia; in the 11th it was sacked by the Seljuks, and subsequently occupied by the Kurds; and in the 12th repeatedly taken by the Georgians. In the 14th century it was finally ruined by an earthquake, and has never since been reoccupied. There are numerous ruins of churches, chapels, and private buildings, while the massive walls, about 6 m. in circuit, are in good preservation. —See *Ruines d'Ani*, by M. F. Brosset (2 vols., St. Petersburg, 1860-'61).

ANICET-BOURGEIS, the popular name of AUGUSTE ANICET BOURGEOIS, a French playwright, born in Paris, Dec. 25, 1806, died at Pau, Jan. 12, 1871. He was a clerk in a lawyer's office, when he wrote in 1825 his first melodrama, *Gustave, ou le Napolitain*. He afterward produced over 200 plays, most of them in conjunction with other authors, though he was the sole author of his best drama, *La Vénitienne* (1834). His fairy plays have had an immense run, especially *Les pîules du Diable*. He is also believed to have been the real author of *Térésa*, *Angèle*, and other pieces ascribed to Alexandre Dumas. His remains have been removed to Paris, where he was buried May 10, 1872. Alexandre Dumas the younger pronouncing the funeral oration.

ANICETUS, a freedman and preceptor of Nero, and commander of the Prætorian fleet at Cape Misenum, A. D. 59. At Nero's instigation he had a false bottom made for a ship which Agrippina was enticed to visit. She barely escaped drowning, and was soon afterward murdered by Anicetus at her villa, near the Lucrine lake. Seneca, in his defence of Nero, used Anicetus's story of Agrippina's plots against the emperor's life. Anicetus also professed to have had an intrigue with Octavia, so as to furnish Nero with a pretext for her banishment. He subsequently lived in luxury in Sardinia with the money given him by Nero in reward for his infamy.

ANIELLO, Tommaso. See MASANIELLO.

ANILIC ACID (Spanish *añil*, indigo), an acid produced by the action of diluted nitric acid upon indigo; also called indigotic acid. Carbonic acid is produced with it, and remains in solution, the anilic acid separating it in light yellowish white prisms, which are fusible and volatile, and dissolve in 1,000 parts of water. Their composition is represented by the formula $\text{C}_6\text{H}_5(\text{NO}_2)\text{O}_2$, H_2O . Anilic acid decomposes acetate of lead, forming with the lead a crystallized anilate.

ANILINE, a substance discovered in 1826 by O. Unverdorben, in the distillation of indigo. At the present time it is almost exclusively prepared by the deoxidation of nitro-benzole by means of nascent hydrogen evolved from iron filings and acetic acid. This operation is graphically represented by the following formulas: $\text{C}_6\text{H}_5\text{NO}_2$ (nitro-benzole) + $6\text{H} = \text{C}_6\text{H}_7\text{N}$ (aniline) + $2\text{H}_2\text{O}$. Aniline is a colorless oily liquid, of a vinous aromatic odor, and bitter burning taste, and in the air turns brown. Its specific gravity is 1.028. It is slightly soluble in water, to which it imparts a weak alkaline reaction. Alcohol, ether, and the fatty oils dissolve it in all proportions. It solidifies at -8°C ., boils at 182°C ., and combines with acids and forms salts soluble in water and alcohol. The faintest trace of aniline can be detected by the deep purple violet color which chloride of lime produces with it. It is an active poison, but its salts are said to be harmless. In 1856 Mr. Perkin, while experimenting with aniline, discovered the beautiful purple dye, which was soon introduced into commerce under the name of mauve. Since that time a variety of colors have been produced, and the manufacture of aniline has become an industry of great importance.

ANIMAL. It is difficult to define the word animal, and even a scientific definition distinguishing an animal from a vegetable is scarcely less so. The assertion of Linneus, that "plants live and grow," while "animals live, grow, and feel," is probably correct; but it is impossible to verify its correctness as applied to the very lowest animals. According to the German naturalists, an animal may consist of a single cell. The idea also till recently maintained, that all animals have a stomach, or internal digestive cavity, is untenable; since many microscopic animals have no trace of a digestive apparatus. Indeed, there is no part or organ common to all animals. The stomach, the heart, and other parts of the circulatory apparatus, the mouth, and even the head, so indispensable in the higher animals, not only in the lower become modified in form and development, but in the lowest even entirely disappear. Nor can muscular fibres or nervous filaments be identified in the latter.—The changes in form of the same organ in different animals can merely be alluded to here. The mouth, for instance, usually single, and opening transversely, is sometimes double, triple, or multiple, and modified into a trunk, or sucker,

as in many insects. The heart has but two cavities in fishes, while there are three in reptiles, and four in birds and the mammalia. The same type of structure, however, often extends over a vast number of species of animals. All the vertebrate animals have the same typical skeleton, it being modified in the various species to suit their requirements. The bones of the anterior extremities, for instance, are the basis of the arm and hand of man, of the fore legs of quadrupeds and reptiles, the wings of birds, and the anterior fins of the whale.—Nor are our investigations in regard to function in all cases more satisfactory. Feeling and voluntary motion are certainly characteristic attributes of all but the lowest animals; but some of the latter are endowed with only a kind of motion of a lower grade than the voluntary, and do not give certain evidence of feeling at all. It is therefore not surprising that it was found impossible for a long time to distinguish the lowest animals from the simplest vegetable organisms; and that to these doubtful structures the name of zoöphyte, or animal-plant, was given. Hence it is not proposed here to attempt to give a precise definition of the term animal, but only some of the more striking particulars which distinguish animals from plants. It should, however, be here remarked, in regard to the microscopic animals, or animalcules, that Prof. Agassiz has shown that many of them are merely the ova, or germs of higher animal forms.—1. An organism manifesting the power of sensation or voluntary motion, or possessing a digestive cavity (stomach), or into whose structure enters the nervous or the muscular tissue, is an animal. But, on the other hand, the impossibility of demonstrating either or all of these characteristics does not prove the organism to be a plant, as before stated. Besides, some plants, as the sensitive plant (*mimosa pudica*), withdraw their leaves from the touch of the hand; but not, as there is every reason to believe, in consequence of either sensation or volition. 2. Albumen is the great nutritive element of animals, while starch is that of plants. Some of the lowest plants (*fungi*) are, however, apparent exceptions to this proposition. Consequently, the chemical composition of the tissues of animals differs from that of plants: the basis of vegetable structure is cellulose, a compound of carbon, hydrogen, and oxygen, while those of animals contain nitrogen also in addition. Recent researches show that cellulose is found in some of the lower protozoa. 3. It has been stated that plants absorb carbonic acid gas from the atmosphere, and give out to it pure oxygen, while animals precisely reverse the process. Plants actually, in their nutrition and growth, assimilate the carbon of the carbonic acid of the atmosphere, and return its oxygen to the latter; but in the respiratory process they, like animals, consume the oxygen of the air, and return to it carbonic acid gas. By day, however, they give off less

of the latter than of oxygen. 4. For the fixation of carbon in the tissues of plants, as just stated, the constant stimulation of light is indispensable. This is not true to the same degree of animals, whose tissues also consist in part of carbon, as has been seen.—In respect to varieties in size, the animal kingdom presents a far wider range than the vegetable. The extremes in the former are the whale, sometimes 100 feet long and weighing as many tons, and the animalcule, of some species of which 30,000 individuals may inhabit a single drop of water; while in the latter we find on the one hand the *sequoia* of California, 90 feet in circumference, and the talipot of Ceylon, a single leaf of which may shelter 20 men from the rain, and on the other the microscopic fungi, as the yeast plant (*torula cerevisiæ*), or those constituting the mould on decaying substances. Dick calculates that the largest trees of Guiana are 2,985,984,000,000,000 times as large as the rose-leaf plant; while the largest whale is to the minutest animalcule as 34,560,000,000,000,000,000 to 1.—The number of species, and probably of individuals, is also far greater in the animal than in the vegetable kingdom. About 70,000 species of plants may be seen in Paris in a single collection. Balbi 40 years ago estimated the whole number of known species at 80,000; and it has been supposed that there are about 250,000 species in all on the globe. On the other hand, there are at least 100,000 species of animalcules alone. Dick estimated the whole number of species of animals at 300,000, and the number of individuals at 24 billions; while the parts and adaptations of these exceed 60,000 billions.—In regard to rapidity of increase, the highest plants vastly excel the highest animals. An elm of average size sometimes produces 158 million seeds. But the lowest animals and plants manifest the greatest power of multiplication. The *borista gigantea*, a species of fungus, has been known to increase its size more than a million times during a single night; and Ehrenberg speaks of an animalcule which propagates so rapidly that its descendants would in four days amount to 70 billions.—The scientific study of the animal kingdom constitutes the department of natural science termed zoölogy. Zoögraphy is merely the description of animals; while zoötomy, or comparative anatomy, is the study of their structure, and zoönomy, or comparative physiology, that of their functions. To facilitate these investigations, a scientific classification of the animal kingdom was first published by Linnæus in 1735, in his *Systema Nature*. This was improved by G. Cuvier, who spent 17 years in perfecting his system (1795 to 1812), which, being based upon the structure of animals, is termed the anatomical system. Modifications have also been made by Lamarek, Virey, Duméril, and De Blainville; but Cuvier's classification is still generally adopted. He arranged the animal kingdom in four great divisions, viz.: I. The

vertebrata (those animals having a spinal column), containing four classes—mammalia, birds, reptiles, and fishes. II. The mollusca. III. The articulata. IV. The radiata. The classes are divided into 72 orders, and the latter into the different genera and species. The classification of Prof. Agassiz, founded on that of Cuvier, is one of the most modern, and in many respects one of the most instructive. It is as follows:

Branch I. RADIATA.

- Class 1. *Polypi*: including the 2 orders, actinoids and halcyonoids.
 " 2. *Aculephæ*: 3 orders—hydroids (including siphonophora), discophora, and ctenophora.
 " 3. *Echinoderms*: 4 orders—crinoids, asteroids, echinoids, and holothurioids.

Branch II. MOLLUSCA.

- Class 1. *Acephala*: 4 orders—bryozoa (including the verticella), brachiopods, tunicata, and lamellibranchiata.
 " 2. *Gasteropoda*: 3 orders—pteropoda, heteropoda, and gasteropoda proper.
 " 3. *Cephalopoda*: 2 orders—tetrabranchiata and dibranchiata.

Branch III. ARTICULATA.

- Class 1. *Worms*: 3 orders—trematods (including cestoids, planaria, and leeches), nematoids (including acanthocephala and gordiacea), and annelids.
 " 2. *Crustacea*: 4 orders—rotifera, entomostraca (including cirripeds), tetracepods, and decapods.
 " 3. *Insects*: 3 orders—myriapods, arachnids, and insects proper.

Branch IV. VERTEBRATA.

- Class 1. *Myxines*: 2 orders—myxinioids and evelostomes.
 " 2. *Fishes proper*: 2 orders—ctenoids (as the perch) and cycloids (as the cod). [This division will probably be considerably modified by its author.]
 " 3. *Ganoïds*: 3 orders—calacanthæ, acipenseroids, and sauroïds; and doubtful the siluroïds, plectognathi, and lophobranchæ.
 " 4. *Schichthians*: 3 orders—chimære, galcodes, and batides.
 " 5. *Amphibians*: 3 orders—caecilia, ichthyodii, and anoutra.
 " 6. *Reptiles*: 4 orders—serpents, saurii, rhizodontes, and testudinata.
 " 7. *Birds*: 4 orders—natatores, grallæ, rasores, and insessores (including scansores and accipitres).
 " 8. *Mammalia*: 3 orders—marsupialia, herovivora, and carnivora.

—As to the chemical composition of animals, probably only 17 out of the 64 simple elements now known, or at most 19, enter into their structure. These are:

Oxygen,	Sulphur,	Magnesium,	Chlorine,
Hydrogen,	Phosphorus,	Sodium,	Fluorine,
Carbon,	Calcium,	Potassium,	Silicon,
Nitrogen,	Iodine,	Manganese,	Bromine.
Copper,	Lead,	Iron,	

These elements, variously combined, form numerous compounds, termed the immediate principles of animal structures, of which in the mammalia there are about 90. Of these, some are of mineral origin, as water, common salt, and phosphate and carbonate of lime. Some are formed within the bodies of animals by disassimilation, as urea, uric acid, and creatine; and others still are obtained from vegetable and animal food for the nutrition of the tissues, as albumen, caseine, musciline, and fat, and hence exist as constituent elements in the latter. These immediate principles unite to form the tissues of which the parts and or-

gans of animals are constituted. These are in the vertebrata as follows:

1. *Epithelial Tissue*:

- A. Epidermis and its modifications—nails, hoofs, horns, scales, and shells.
 B. Hair and its modifications—bristles, wool, and feathers.
 2. *Elastic Tissue*, its properties mucil. resembling those of gun elastic.
 3. *White Fibrous Tissue*, in tendons, ligaments, &c., very strong and almost totally inextensible.
 4. *Ossaceous and Dental Tissues*, in bones and teeth.
 5. *Areolar Tissue*, connecting the various organs together.
 6. *Adipose Tissue*, otherwise called fat.
 7. *Cartilage*, in the joints, those of the ribs, &c.
 8. *Muscular Tissue*, the source of motion.
 9. *Nervous Tissue*, the seat of sensation and intelligence.
 10. *Membranes*, cutaneous (skin), mucous, and serous.
 11. *Glands*, the secretory organs.
 12. *Vessels*, the blood vessels and the lymphatics.

The tissues of animals are developed directly from the vital fluid, the blood. This in all the vertebrata is red, from the presence of minute cells containing a colored fluid, and which are called the blood corpuscles. In the invertebrate animals no such corpuscles exist, and therefore the blood is colorless. Hence the division of animals into the red-blooded and the white-blooded. The blood of each animal in the central parts of the body has its peculiar natural temperature, that of man being 98° to 99° F. The temperature of all animals lower in the scale than birds is lower than that of human blood, and hence all these are called cold-blooded, while birds and the mammalia are termed warm-blooded animals.—The fecundity of animals also varies inversely with their elevation in the scale. While mammals produce from 1 to 8 or at most 10 young at a time, a tench produces 38,000 and a mackerel 546,000 eggs; and Leeuwenhoeck professes to have counted 9,384,000 eggs in a single codfish. Some of the mammals are, however, very prolific. Pennant calculates that the descendants of a single pair of rabbits would, without interference, amount in four years to 1,274,840. But external circumstances exert a powerful influence in this regard. For instance, the pigeon in its wild state broods but twice a year, but when domesticated six, and sometimes even nine times. In the latter case, a single pair would in four years produce 14,762 descendants according to Stillingfleet, and according to Linnæus, over 18,000. The astonishing fecundity of some of the animalcules has already been illustrated. The mammalia alone bring forth their young alive, the duration of gestation being as follows in the following species: elephant, 20 months and 18 days; rhinoceros, 9 months; horse, 11 months; ass, 12 months; cow, 9 months; reindeer, 8 months; buffalo, 12 months; sheep and goat, 5 months; foxes and wolves, 5 months; Greenland whale, about 10 months.—Obviously there must be a correspondence of the structure of an animal to its habits and functions. For example, a carnivorous animal must have great strength and powers of locomotion, enabling it to overtake, seize, and de-

stroy its victim. It must therefore have largely developed muscles and strong bones, and the teeth and jawbones must be especially strong, and the former of a peculiar form for tearing animal tissues. Such an animal must also have an acute sense of smell and of hearing, and a corresponding structure of the organs of these two senses. It is therefore not wonderful that Cuvier could construct an entire animal from having a few of its bones given, and that Agassiz has deduced the form and structure of a fossil fish from its scales alone.—What is nourishment to one animal may prove to be poison to another. Pallas states that hedgehogs eat abundantly of cantharides without inconvenience. The sphinx of a species of caterpillar feeds on the acrid and poisonous juice of the milk thistle (*tythimalis*), and a certain worm on the leaves of the tobacco plant. Bees feed on and obtain honey from the secretions of many poisonous plants; and a kind of buzzard devours the nux vomica. Most animals, however, confine themselves within certain definite limits so far as the sources of their nourishment are concerned. Even the hog, which is usually spoken of as omnivorous, may be mentioned in illustration. It has been found that the ox eats 276 and rejects 218 plants; the sheep, 387 and 141; the goat, 449 and 126; the horse, 262 and 212; while the hog eats but 72 and refuses 171. This animal, therefore, except in cases of necessity, evinces even a superior discrimination in the selection of its food. Some animals never drink at all, drink not being required if the food contain a large amount of water, as is the case with the succulent plants. The gemsbok and the eland, two species of antelope, are thus adapted to the sandy deserts they inhabit.—The amount of food required by animals depends upon its quality and their activity. A far less bulk of animal than vegetable food is required; and the greater the activity, the greater is the waste of the tissues, and the more nourishment is needed to repair them. The intervals of fasting are therefore determined mainly by this circumstance. While birds are eating most of the time when not asleep, reptiles pass months in succession without food, in the mean time being in a dormant state. And those of the mammalia which hibernate (as the dormouse, hedgehog, marmot, &c.) also pass the entire winter with little or no food. The sloth also has been known to suspend itself on a pole for 40 days without taking food. But irregularity of supply of food must also be taken into account. The griffin vulture will retain its vigor for five or six weeks without food; but when opportunity recurs it does not leave its repast for days, or so long as a morsel of flesh remains, so completely gorging itself that it is incapable of rising on the wing till it has ejected the contents of its crop. A total privation of food is longest endured without fatal consequences by animals manifesting the lowest vital energy. Fourteen persons, male and female, survived

starvation on being shipwrecked for 23 days. An eagle lived 28 days, and several dogs 36 days without food. On the other hand, land tortoises have been kept alive 18 months and serpents for five years without food. The requirements of different animals in regard to their food will determine the limits on the globe within which each species will thrive; and this, together with the temperature required by each, is the principal agency determining the geographical distribution of the various species of the animal kingdom.—The greatest amount of strength and endurance is possessed by the warm-blooded animals; birds being the strongest of all animals in proportion to their size, except certain insects. The lion is capable of bearing off large animals, and has been known to leap over a broad ditch with a heifer in his mouth, and to break the back of a horse with a single stroke of his paw. The grisly bear, weighing 800 lbs., can drag the carcass of a buffalo weighing 1,000 lbs. to a considerable distance. The camel sometimes carries a weight of 1,000 lbs. 30 miles a day, and judges so accurately of its powers that, being accustomed to lie down while loaded, it refuses to rise till a part has been taken off, if too heavy a burden is imposed. The horse is about six times as strong as a man, his power being estimated at 420 lbs. at a dead pull. He cannot, however, carry more than three times as much weight up a steep hill. A Canadian shrew mole, whose body was but four inches long, being let loose in a room, passed between the legs of some heavy chairs and the wall with which they were in contact, throwing them aside without much apparent effort, and at last hid itself behind a pile of quarto books more than two feet high, which it also moved from the wall. This animal also burrows so quickly, that on being let loose in a yard it almost instantly disappears beneath the surface of the ground. On the other hand, the sloth is so averse to all effort that, when it has satisfied its appetite upon the fruits of trees, it falls to the ground to save itself the labor of descending.—As instances of fleetness of animals, the kangaroo, the hare, and the antelope may be alluded to. The first progresses by a rapid series of leaps, frequently of 20 feet, its own body being from 5 to 6 feet in length. The hare sometimes passes over 25 feet at a single bound. The springbok bounds to the height of 10 to 12 feet, clearing at each leap from 12 to 15 feet without any apparent exertion. Even the sheep in its wild state runs and leaps with great agility. The movements of the dolphin are also very rapid, and it leaps so high out of the water as sometimes to throw itself upon a ship's deck. The ostrich will at the outset outstrip the fleetest horse. The nandu (allied to the ostrich) is equally fleet, and when caught kicks so violently as to break even stones. The carrier pigeon flies 25 to 30 miles an hour. The dragoon pigeon has flown from Bury to London, 72 miles, in $2\frac{1}{2}$ hours.

Spalanzani states that two swallows flew from Milan to Pavia, 18 miles, in 13 minutes. The precision and rapidity of muscular action of some animals is also remarkable. The elephant can pick up a pin with its huge trunk. The chamois goat leaps with the greatest precision from point to point on the mountain rocks, alighting on surfaces scarcely large enough for its feet to rest upon. A bird called the wryneck, having a long tongue like the woodpecker, darts forth and retracts this organ with such rapidity that the eye is unable to follow it. The frog also catches flies by movements scarcely less rapid.—No animal possesses more than five senses, and some are probably endowed with not more than one, the sense of touch. But we find each sense manifested in the animal scale, in all grades of perfection. Of intelligence, also, we find great varieties in birds and mammalia, while below the former we hardly find any higher attributes than mere instinct. This, indeed, predominates in most birds, and in the mammalia often assumes the appearance of cunning, artifice, or sagacity. The Egyptian ichneumon, being fond of poultry, feigns itself dead till the birds come within its reach, when it springs upon and strangles them, usually contenting itself with sucking their blood. There is a species of musk which also feigns death when caught in the noose set for it, but escapes the moment it is untied. The European cuckoo neither builds a nest for itself nor hatches its own eggs. It deposits a single egg in the nest of the hedge sparrow (and sometimes of the wagtail or the titlark), while the other bird is laying her eggs. This addition to her charge disturbs her arrangements, and during incubation she throws out her own eggs, or so disturbs as to addle them, to make room for the cuckoo's; but, according to Dr. Jenner's observations, she never displaces the latter. When some of her own eggs and that of the cuckoo are hatched, the young cuckoo manages to throw out the young sparrows and the remaining eggs, and thus gets the whole nest to itself. The ostrich surrounds her nest with a trench, in which she deposits some of her eggs as the first food of the young ones to be hatched from the eggs in the nest.—To an animal capable of being educated, though to a slight extent, we cannot deny the possession of intelligence; and judged by this criterion, most of the mammals and some birds must be regarded as possessing this attribute. The adaptation of means to ends, in entirely new circumstances, must also generally be attributed to it rather than to mere instinct. Swallows club together to repel a common enemy, many closing round a hawk. A martin being caught in a noose of packthread, fastened at the other end to a gutter, all the martins in the vicinity were attracted by its cries, and, striking the thread with their bills, succeeded in setting him at liberty. The superior intelligence of the elephant is often asserted; but this animal is really less intelligent than the dog, and about

equal in this respect to the horse. As tested by educability, as well as by acquired tastes, the quadrumana are far the most intelligent of the lower animals.—Carnivorous animals are mostly solitary in their habits, while many of the herbivorous are socially inclined and gregarious. This is the case with the llama and the horse in the wild state. Camelopards herd together usually in companies of 16. Antelopes are found in herds of 2,000 or 3,000, or in small parties of only five or six individuals. The males also of antelopes and deer frequently consort together, independently of the females. On the other hand, the conjugal attachment of the stellerine (allied to the dugong) is so great that if the female be taken, the male will dash on shore to her in spite of blows, with the swiftness of an arrow. Some animals are docile and yielding, others obstinate. The mule is proverbial for the last attribute, but the llama is still more remarkable in this respect. Some animals are grave or morose, while others are playful, and even have their peculiar amusements. The mocking-bird amuses itself in frightening other small birds by imitating the screams of the sparrow hawk.—The particular classes and orders of animals will be described under the appropriate heads; the four classes of the vertebrata forming the articles AMPHIBIA, HERPETOLOGY, ICHTHYOLOGY, MAMMALIA, and ORNITHOLOGY; while the invertebrata will be found described under the heads ANIMALCULES, ARACHNIDA, ARTICULATA, CRUSTACEA, ECHINODERMA, ENTOMOLOGY, EXTOZOA, EPIZOA, MOLLUSCA, PROTOZOA, and RADIATA.

ANIMALCULES, a name familiarly applied to the more minute forms of animal life, for the knowledge of which we are mainly indebted to the microscope. Leeuwenhoek led the way in this as in most other branches of microscopic study; but it is to Gleichen that we are indebted for the first attempt at the systematic study of the subject. He was followed by the Danish microscopist O. F. Müller, who made the first regular classification of animalcules. Subsequent observation has detected many errors in the classification of Müller, and it has now little other than a historic interest. It is to Ehrenberg that we are indebted, directly or indirectly, for almost all our knowledge of these forms. Since the appearance of his work, *Die Infusionsthierchen*, the study of minute animal forms has been ably pursued by Dujardin in France, Siebold, Kölliker, and others in Germany, Owen in England, and Bailey in the United States.—The earlier observers grouped together, under the term animalcules, a vast variety of living beings having nothing in common except their minuteness of size. Plants and animals, mollusks, crustaceans, insects and worms, larvae and perfect forms, all were aggregated together under the vague term animalcules. The labors of modern scientific men have been in great part exhausted in the distribution of this mass of animal and vegetable life among the various

classes, families, and orders to which its heterogeneous materials properly belong, and the formation of a class to which the name *infusoria*, first proposed by Müller, is now generally applied. To this class we shall confine ourselves, and shall generally use the term infusoria, not that it is absolutely accurate, for though the greater number of these animals are developed in infusions, yet this rule is not without some striking exceptions.—If a drop of water in which animal or vegetable matter is decaying be placed upon the object-holder of a microscope of adequate magnifying power, say 200 diameters, it will be found to swarm with living beings in active and incessant motion. They vary in size from $\frac{1}{100}$ of an inch, when they are just within the limit of unassisted vision, to a minuteness which it tasks the power of the glass to detect. These are infusoria; they abound in every ditch, pond, lake, or river, are equally numerous in salt as in fresh water, have been found in thermal springs of high temperature, and in the melted snow of the Alps and the Andes; in short, wherever water and decaying vegetable or animal matter exist, these infusorial animals will be found in vast numbers. There is no doubt that they are often drawn up into the atmosphere in watery vapor, and borne to and fro by the winds. Many forms are not deprived of life by complete desiccation, and may therefore be mingled with the dust, and in this condition carried about by the winds, to resume their active vitality so soon as they chance to fall into water. The suddenness with which they appear in water, even distilled water, when exposed to the air, furnished the advocates of spontaneous generation with one of their strongest arguments.—Infusorial animalcules have neither vessels nor nerves, and are made up of a uniform tissue, called by Dujardin *sarcodæ*, and by Huxley *protoplasm*. This is in some classes of nearly uniform consistence; in others the external layer possesses considerably more density than the internal, while in yet others a distinct pellicle or skin can be made out. They have no true feet; a few of the very lowest type have the power of protruding portions of their homogeneous structure in the form of limbs, which they use both for the prehension of their food and for locomotion. In the higher forms the locomotion is by cilia, or very minute hairs. This motion is probably automatic, as it is constant day and night, the animal never sleeping, nor appearing to take rest. Yet it certainly has in some cases many of the characteristics of spontaneity, the animal in his rapid course seeming to avoid obstacles; but the subject of the character of the locomotion of these animals is very obscure. Some of these higher forms have a shell or outer coat, called carapace or lorica; these are spoken of as loricated.—We have already intimated that the systematic classification of the infusoria has been a matter of great difficulty. That of Ehrenberg, to which we shall in the main conform, though

possessing great merit, has also very great defects. He includes among his infusorial animals very many large and important families which are now known to belong to the vegetable kingdom. His *desmidiæ* are now very generally, we might almost say universally, admitted to be *algæ*; and his *diatomacæ* are now also placed in the vegetable kingdom. The classification of Dujardin, though it has some great advantages over that of Ehrenberg, is deformed by a multitude of new terms, or, what is worse, old terms to which he affixes new significations. The two great obstacles which at present forbid even the hope of success in any attempt at systematic classification of infusoria are: 1, the great difficulty of distinguishing the lower forms of animal from the corresponding forms of vegetable life; 2, that of deciding whether a given form is permanent, or whether we have to do with the larvæ of an insect, or some one of those forms which crustaceans, polyps, and other of the lower animals assume in the progress of their alternations of generation. A motion apparently spontaneous was formerly supposed to decide the question in favor of an animal nature; but Vaucher of Geneva (1790) proved that a motion not to be distinguished from the spontaneous movements of animals is common in the spores of the simpler aquatic plants, and is indeed nature's provision for their dispersion. That animals absorb oxygen and give out carbon, while plants give out oxygen and absorb carbon, affords in the opinion of many naturalists the desired test. But although this is a very general, it is not found to be a uniform law. A third distinctive mark, and probably the most useful, is found in the character of their nutritive material—plants being nourished by inorganic, animals by organic food. There are some exceptions to this rule also, but they are not numerous, nor do they greatly detract from its practical value. Agassiz has satisfied himself that very many of Ehrenberg's genera are germs of aquatic worms, and he suggests that this is probably the true nature of all the infusoria. Should this idea prove well founded, the most essential changes will of course be necessary in the arrangement of the infusoria—if, indeed, it is not found necessary to break up this class altogether, and distribute the individuals of which it is composed throughout the lower divisions of the animal scale. But meanwhile we shall adopt the classification of Ehrenberg, eliminating from it those families on whose vegetable nature the great mass of naturalists are agreed. Ehrenberg divides the infusoria into *polygastrica* and *rotatoria*. The characteristic of the former is the appearance of certain internal cavities, which he supposed to be dilated portions of the alimentary canal, or stomachs; hence their name polygastric, or many-stomached. The rotifera, the so-called wheel animalcules, are distinguished by a peculiar arrangement of cilia upon lobes near the mouth, which, when in a state of active vibra-

tion, give to the lobes the appearance of wheels in rapid motion. These so-called wheel animalcules are, however, so widely different in their plan of structure, and so much higher in their degree of organization than the polygastrica, that naturalists have very generally separated them from the infusoria, and have placed them among the entomostracan crustaceans. We shall, however, treat of both in the present article. I. POLYGASTRIC INFUSORIA. It is unfortunate that the name polygastric, or many-stomached, is taken from a supposed peculiarity of the animal, the existence of which in any of the class has been rendered by later researches more than doubtful, and the absence of which in some families is admitted by Ehrenberg himself. By retaining this name, we commit two verbal inconsistencies: 1, in calling animals many-stomached which have probably no stomach at all; and 2, we form a subdivision of these polygastrica, the characteristic of which is the absence of any digestive tube. Following Ehrenberg, then, we base the first great division of the polygastric infusoria on the presence or absence of an alimentary canal. Those in which it does not exist he calls *anentera*; those in which it does, *enterodela*. Of the *anentera*, some have the power of protruding a portion of their homogeneous bodies as a foot-like process; and of these some have a shell, or, in scientific phrase, are loricated, others are non-loricated. The former are called *areollina*, the later *amæba*. Of the remainder, some are furnished with cilia, others are not. To the former the term *dinobryina* is applied when they are loricated, and *astasiaea* when they are not. The non-ciliated, in like manner, are called *peridina* when loricated, and *eyclidina* when naked. The *enterodela*, or polygastrica having a digestive canal, are divided in the same way into two parallel series, as they have or have not a lorica or shell. First in this parallel series are placed those where the orifice of the digestive tube is single; these are *vorticellina* and *ophrydina*. Next come those with two orifices at opposite ends of the body; these are *exchelina* and *colepina*. Next are those where the two orifices are irregularly placed, the *aspidiscina* having no shell, the *trachelina* and *ophryocercina* each having a shell; the former having a proboscis but no tail, the latter a tail and mouth anterior. Lastly, those having two ventral orifices: the *euplota*, where the shell is present, and the *kolpoda* and *oxytrichina*, the former moving by cilia, the latter by other organs, neither having a shell. A diagram will perhaps make this classification more intelligible:

POLYGASTRIC ANIMALS.

ANENTERA, having no digestive tube.

	Loricated.	Non-loricated.
A. Protruding part of the body like feet.	AREOLLINA.	AMÆBÆ.
B. Having cilia.	DINOBRYINA.	ASTASIAEA.
C. Non-ciliated.	PERIDINA.	CYCLIDINA.

ENTERODELA, having a digestive tube.

A. One orifice to the digestive tube.	} VORTICELLINA.	OPHRYDINA.
B. Two orifices at opposite ends of the body.		
C. Two orifices irregularly placed.	TRACHELINA. a proboscis but no tail.	} ASPIDISCINA.
	OPHRYOCERCINA a tail and an anterior mouth.	
	KOLPODA moving by cilia.	
D. Two ventral orifices.	EUPLOTA.	OXYTRICHINA, moving by other organs.

—As to structure, we have already stated that neither nerves nor vessels have been discovered in infusoria; indeed, in the very lowest class, the *amæba* and *areollina*, which are by Dujardin called *rhizopoda*, and by other writers *pseudopoda*, we find life manifesting itself almost without organization. The *amæba* is a jelly-like mass, without determinate shape, in texture nearly uniform, having no integument; in fact, only differing from a mass of jelly in being slightly more fluid in the centre than at the circumference, and having at some point near its surface a vesicle, perhaps only a vacuole, which pulsates pretty regularly. When this creature is about to move, a current of the more fluid central portion is seen tending toward some one point of the circumference; soon a portion of the mass protrudes, it elongates till perhaps double the length of the animal, the mass of whose body then seems to pass into the protruded and elongated portion, and thus locomotion is effected. The mode of taking food is thus described by Kölliker, who studied it in the *actinophrys*, a genus closely allied to the *amæba*, and like it made up of a mass of jelly, portions of which, scarcely differing from the general mass in structure, are protruded in the form of rays: "The mode in which the actinophrys is nourished is one of the highest and most special interest. Although the creature has neither mouth nor stomach, yet it takes in solid nutriment, and rejects what is indigestible. This miracle, for so it may almost be called, is thus effected: When in its progress through the water the actinophrys approaches any small plant or animal—a minute crustacean, rotifera, the young of cyclops, or the lower *algæ diatomacea* for instance—as soon as the mass is touched by one of the rays of the actinophrys, it seems to adhere to it; the ray now slowly shortens itself, and draws its prey to the surface of its own body; the surrounding filaments attach themselves to it, bending their points together, and closing over it till it is enclosed on all sides. Gradually a cup-like cavity is formed in the body of the actinophrys, at the base of the ray, and into this the prey is crowded, till the cavity still growing deeper, the whole mass comes to be imbedded in the very substance of the animal, which gradually closes around and over it, and thus the mass comes to be contained in a cavity or stomach formed for its reception. Here it is digested, and its nutritive portions absorbed; and when this is ac-

complished, the undigested portion, if any such remain, is protruded toward the surface, and finally emerges from the body of the animal as it might from a mass of jelly; the opening by which it escaped closes behind it, and the animal resumes its pristine form and condition." Of the mode of reproduction in these animals, we only know they multiply by self-division, and that when portions of the mass are cut or torn away, these maintain an independent existence, and soon acquire the shape and functions of mature animals. Of their proper sexual reproduction we know nothing, although all analogy leads us to suppose that this multiplication by division, whether spontaneous or artificial, must have its limit, and a proper sexual reproduction by germ and sperm cells be interposed.—Ascending in the scale, we come to those polygastric infusoria which have a proper digestive canal—the *enterodella* of Ehrenberg. Though the existence of an alimentary canal is made the characteristic of this group, its presence in any of the genera is by no means certain. All have beyond controversy a mouth into which food is taken, and many have an anal orifice from which excrement is discharged; but whether there is any canal with definite walls through which the food passes, as in the higher animals, is doubted by many naturalists, and denied by not a few. Ehrenberg indeed traced the course of the canal passing very nearly straight in the length of the animal's body in some genera, convoluted in others, and in a third class winding in a spiral around the inner surface of the body, with flask-like appendices communicating with its cavity, and making up the great mass of the body. But the disciples of Ehrenberg, working with the best modern improved microscopes, have not been able to satisfy themselves of the existence of this so-called digestive tube. A mouth and a short, generally ciliated œsophagus, these animals certainly have; but the existence of an alimentary canal, beyond this short gullet, is very doubtful. The infusoria of this class differ from the *amaba* and other *rhizopoda*, in that they have a true investing membrane or skin, which in some families can be detached as an independent membrane; and from the internal surface of this membrane partitions are sent off, which divide the general cavity of the body into separate chambers. In these the jelly-like tissue of the animal, the *sarcode* of Dujardin, is lodged; and into these chambers the food, when it has escaped from the œsophagus, is received; it passes from one to the other till it has made the circuit of the body, not, however, with much regularity, and is in its course digested; and all of its alimentary substance being absorbed, the residue is ejected either by the mouth or by an anal orifice. Thus is the function of digestion performed in the *enterodella*.—It was stated in the definition of the infusoria, that they have no nerves or blood vessels. Nervous matter has certainly never been detected in any of the

class; and although Ehrenberg supposed that two colored (generally red) spots, which are found pretty constantly near the anterior part of the body, are eyes, yet, as he was equally confident of the existence and nature of these spots in some forms which undoubtedly belong to the vegetable kingdom, it is probable that he was in error as to these. In most polygastric infusoria, small vessels which appear to contain a clear, nearly colorless fluid, are found, which enlarge when full, and when empty contract so as to be scarcely visible. Their number varies from a single one to ten or twelve; they usually occupy the same place in individuals of the same species, and their contents seem sometimes to be propelled from one to the other. They are probably receptacles of nutrient fluid stored up for the use of the system. Another remarkable peculiarity of the infusoria is, that in the very substance of their bodies may generally be found a solid granular-looking mass of very variable form—round, oval, curved, or even in some cases branched—by some called the nucleus. By Ehrenberg it was said to be a testis; and although this opinion has found little favor with the more recent observers, yet that this peculiar mass has a very important connection with the reproductive function cannot be denied. When the infusoria are about to multiply by self-division, the separation always begins in the nucleus. May not this be a mass of germ cells, such as we see in those insects which, after one sexual connection, continue throughout a succession of generations to bring forth young, till the mass of germ cells is exhausted, and a second sexual act is necessary to continue the multiplication of the species? In none of the infusoria has any muscular or contractile tissue been found, though the very lowest form, the *amaba*, possess the function in an eminent degree. Here, as ever in the animal scale, function precedes organization; and the function of muscular contractility is manifested while there is as yet no appearance of muscular tissue. The stalk of the *vorticella* forms a notable illustration of this rule, as it possesses contractility in a remarkable degree, yet no muscular tissue is to be found in it.—Reproduction is effected in different ways in the different forms; the mode which has been best studied is that by spontaneous self-division. This is sometimes longitudinal, sometimes transverse. As before stated, it begins in the nucleus, and this body is often completely divided while the line of future separation has scarcely begun to appear on the surface of the animal. These subdivisions are completed in so short a time, that Ehrenberg has calculated that no fewer than 268,000,000 may be produced in the space of one month from a single individual. Another mode in which new individuals are formed is by what is called conjugation. Two individuals attach themselves together, till at length their entire bodies coalesce and form one, in the interior of which a new individual is formed, and in pro-

cess of time discharged from the parent body, either by splitting or through some orifice. Yet another mode of reproduction has been observed by Stein and other microscopists. It has been called the encysting process; and although it has been studied in relation to but few forms, yet the facts already established render it very probable that many, if not indeed all the infusoria multiply by this or some closely allied process. An infusory animal about to become encysted secretes from the surface of its body a thick glutinous substance, which, gradually hardening, forms a firm case in which the animal is shut up, but not so closely as to prevent tolerably free motion. A change now takes place in the animal itself; the cilia upon its surface are retracted, and the body assumes a pretty regular circular outline; then either the whole body, or the nucleus only, breaks up into many small fragments, each of which assumes an independent life, and moves freely in the parent organism; this mother-cell now bursts and is disintegrated, while the young brood swim forth either in the form of the parent, or in some transition shape, from which, through one or more changes, they pass into the permanent type identical with the parent organization.

II, ROTIFERA OR WHEEL ANIMALCULES. These have little in common with the order of infusoria of which we have spoken, being both more highly organized and formed on a different plan. Even in respect to size they differ, being generally much larger, some having a length of half a line, and many being within the limit of unassisted vision. By many naturalists they are classed with the articulated animals, under the term of cilio-articulates. Their name, as we have already stated, is derived from a particular and very curious arrangement of the cilia covering two lobes near the anterior extremity, which when in motion have exactly the appearance of two minute wheels rotating very rapidly. But this, though a striking peculiarity of many rotifers, is not common to them all. In some the cilia about the head are arranged in a wavy line. The rotifera may be defined as minute worm-like animals, very transparent, without legs, having the anterior portion of the body furnished with certain retractile lobes, the margins of which are covered with cilia, the alimentary canal distinct and having two orifices, the mouth having a true dental apparatus, the reproduction by ova only. They are aquatic, though a few species can exist in moist earth. They are found alike in salt and fresh water, but rarely in that which is rendered foul by decaying vegetable and animal matter, and which swarms with the polygastric animalcules. It is only when these have devoured the decaying matter that the rotifer appears to feed upon them. Rotifera have great tenacity of life, and are not destroyed by complete and long-continued desiccation. Individuals have been kept in vacuo with sulphuric acid and chloride of lime, insuring the utmost possible amount of dryness,

for a month, and yet revived on being placed in water. The rotifera have always two investing membranes, both transparent, and the inner always flexible; the outer is in many quite firm, constituting a horn-like tube, from which the head and tail of the animal protrude. It never contains either lime or silica, which is probably the reason why no traces of these animal forms are found in any fossiliferous rocks. Their bodies are retractile, and many creep like worms. They swim by means of their cilia very rapidly. Near the tail is, in most forms, either a dirk-like or claw-like process, by which the animal can attach itself. The gullet is furnished at its inferior portion with a masticating apparatus consisting of two strong semicircular jaws, each furnished with from one to five teeth, which appear to contain mineral matter. The stomach is either globular or tubular, and scarcely distinguishable from the intestine below. Near the anus the intestine is enlarged into a sort of cloaca with which the genital apparatus communicates. Several small glandiform bodies are observed near the alimentary canal, and some undoubtedly communicate with its cavity. It is a curious fact that, though the digestive apparatus is in most of these animals much more fully developed than any other, yet in one genus described by Mr. Dalrymple ("Philosophical Transactions," 1849, p. 339), no anal orifice was found, and indeed scarcely any intestinal canal; so that the excrementitious food must have been ejected from the mouth, as in some of the very low polygastric forms.—We now come to locomotion. Several distinct longitudinal bands of a highly contractile tissue pass the entire length of the animal, and certain transverse bands have probably the same power. It is, however, very doubtful whether any true muscular tissue, with the characteristics by which we identify it in the higher animals, exists in these animalcules. The same remark applies to the nervous system. The function is certainly performed; but whether the cords and masses which Ehrenberg describes as nerves and ganglia really have that character, is at least uncertain. Two red spots near the head are supposed on pretty strong evidence to be eyes, or at least rudimentary forms of the organ of vision. There is no proper circulatory apparatus, but water is very freely admitted into the body, and probably serves to aerate the tissues. It is kept in motion by cilia lining the tubes into which it is received.—*Reproduction.* All that is certainly known upon this subject is that the rotifera multiply by true ova, and never by gemming, budding, or spontaneous splitting, like the polygastrica. Until recently they were generally supposed to be hermaphrodite, but some late observers believe them to be unisexual. Ovaries are made out without difficulty, and in the vast majority of individuals; but spermatozoa have been found in only a very few, perhaps only one species. If males exist as a separate sex, they are probably

only developed at one period of the year, and their term of existence is very short. This is rendered probable by a very curious observation made by Mr. Dalrymple. He found in one genus male individuals, that possessed neither mandibles, nor alimentary canal, nor glands. The only apparatus that was fully developed was the generative. The animal was in fact a mere male genital system, endowed with power of independent existence, though that existence must have been of very short duration. The transparency of the tissues enables us to trace very satisfactorily the formation and progress of the ova. Their growth is very rapid, and they are in some genera extruded from the ovary two or three hours after their germ is first detected, and hatch in less than half a day. In other families the eggs remain in the ovary or cloaca, and are there hatched, the young being born alive. From the transparency of all the tissues, it is often possible to trace the form, and to a certain extent make out the details of the structure of the young animal while it is yet in the body of the parent.

ANIMAL ELECTRICITY, electricity produced in the bodies of animals. Of this electricity there are two kinds, the dynamical or galvanic and the statical. 1. *The production of dynamic electricity.* Few discoveries in science have more importance than the almost accidental observation made by Luigi Galvani in 1786. After having examined the influence of the shock produced by a spark of the electrical machine on a frog's leg, Galvani observed a new and very curious phenomenon. He had skinned a frog, taking away its two legs with a part of the spine, and attached the whole to a copper hook which he had hung upon an iron railing near his laboratory. He stood watching to see if the electricity of the atmosphere would produce upon these legs the same effect as an electrical machine. After some time, having observed no sign of electrical influence, he decided to remove the frog's limbs, and while doing so he perceived the very muscular contraction which he had been vainly expecting to see produced by atmospheric electricity. He soon discovered the condition of this contraction, which was the contact of the moist limbs of the frog with the iron rail. Having substituted for the copper hook and iron rail a metallic arc composed of pieces of these two metals, he found that he could produce the contraction at will. For the production of sudden muscular contraction and of a movement of the limb, it was only necessary to place one end of the arc in contact with a nerve or with the spinal canal, from which the nerves emerge, and with the other end one of the muscles of the leg. Galvani first published these experiments in 1791, in his celebrated work, *De Viribus Electricitatis in Motu Musculari Commentarius*. According to the theory proposed in this work, the muscles chiefly contain the animal electricity which manifested itself

in the above experiments, and which he thought was supplied by the nerves and the blood. When the discoveries of Galvani became known, the whole civilized world was seized with admiration, and the curiosity to witness his experiments became universal. Du Bois-Reymond says: "Wherever frogs were to be found, and where two different kinds of metal could be procured, everybody was anxious to see the mangled limbs of frogs brought to life in this wonderful way. The physiologists believed that at length they should realize their visions of a vital power. The physicians, whom Galvani had somewhat thoughtlessly led on with attempts to explain all kinds of nervous diseases, as sciatica, tetanus, and epilepsy, began to believe that no cure was impossible." Volta soon opposed the views of Galvani, and maintained that the pretended animal electricity was nothing but the electricity developed by the contact of two different metals. Galvani replied that with one metal only the muscular contraction was produced, although very feebly. Volta answered that the metals employed were not pure, and that as they had no homogeneity they acted like two metals. He showed that even the least physical alteration of a part of an arc of one metal was sufficient to make it act as if it were composed of two metals. Galvani, however, succeeded in producing contractions without the intervention of any metal whatever, by merely applying the nerve of a leg on the muscles or establishing a communication between the muscles and the nerve by a piece of moist animal tissue. Alexander von Humboldt took sides with Galvani against Volta. In employing very irritable frogs he found that there were strong muscular contractions in the following circumstances: 1, when the leg of a frog was bent back against the ischiatic nerve, both parts being still originally connected; 2, when the crural nerve and its muscles were connected by a fragment cut from the same nerve; 3, when a connection was established between two parts of the same nerve by means of some animal tissue. In 1798 Galvani died, and the next year Volta discovered the pile; and, as it has been said, he then earned the right of exclaiming, with triumphant scorn, "I don't need your frog; give me two metals and a moist rag, and I will produce your animal electricity. Your frog is nothing but a moist conductor, and in this respect it is inferior to my wet rag." For nearly 30 years the supporters of the theory of animal electricity were silenced by the great discovery of Volta.—In 1825 Nobili, having rendered extremely sensitive the galvanometer (instrument for the measuring of galvanic currents), thought that the current which produces muscular contractions in the frog's legs might be detected by his instrument. He failed in his first attempt, the contractions taking place while the needle of his instrument stood still; but after having improved the instrument Lo

succeeded in obtaining a notable deflection of the needle. Unfortunately for the progress of science, Nobili admitted that the current formed in muscles was due to a difference of temperature between the nerves and the muscles. Nevertheless, he left to his successors some facts of great importance, the most interesting of which is that when the legs of several frogs are disposed in such a way that the nerves of one touch the muscles of another, this kind of pile increases in power with the number of legs.—To Prof. Carlo Matteucci belongs the merit of having positively proved the production of galvanic currents in muscles. His researches, those of Du Bois-Reymond, of Donné, of Baxter, of Brown-Séguard, of Eckard, and others, have established beyond doubt that a production of electricity is constantly going on in all the tissues of the living animal economy. The following facts, among others, have been well demonstrated: 1. When the electrodes or conductors of a galvanometer are applied one on one surface, and the other on another surface, of the animal body, a current takes place which moves the needle of the instrument. Thus Donné found a current between the skin and most of the internal membranes; thus Matteucci ascertained that there are different electrical states in the liver and the stomach; and thus also Baxter found a current between the internal surface of an intestinal vein and any part of the mucous membrane of the bowels. 2. There are electrical currents in muscles and nerves, as we will show hereafter. 3. All the organs of the body yield electrical currents when they have been divided, and when their normal surface and the surface of the section are in communication with the electrodes of a galvanometer.—No one has been more successful than Du Bois-Reymond in experimenting upon the production of galvanic or electrical currents in the various parts of the body. He owes his success in a great measure to his galvanometer, which admirable instrument, made by himself, is so sensitive that the exceedingly weak current from two parts of the skin, even very near each other, is felt by it. The wire wound upon the frame of this apparatus is 5,584 yards or more than 3 miles long; it forms 24,160 coils around the frame. However, it is not necessary to employ such a powerful instrument to prove the existence of animal electricity, and the ordinary galvanometers may answer the purpose. Before the researches of Du Bois-Reymond it was admitted that there were two kinds of muscular currents, one belonging to divided muscles and the other to undivided muscles. The first had been very well observed by Matteucci, who ascertained that it is constantly directed from the interior of the muscles to its surface. It exists in the muscles of all the animals which have been examined, and Brown-Séguard has found it in man. As to the other current, that of undivided muscles, it is what Nobili called the proper current of the frog.

Du Bois-Reymond found that this current exists also in the higher animals, and that its direction varies extremely according to many circumstances. In the limb of the frog this current is directed from the tendon of the principal muscles to their surface. If in certain animals the current seems to be weak, although it may be in reality strong, it is because in some muscles the tendon is placed at one extremity and in others at the other, and that sometimes there are two tendons.—The galvanic current of muscles gradually diminishes after the death of animals, or after the separation of the muscles from the living body. According to the researches of Du Bois-Reymond, and numerous experiments made by Brown-Séguard, the laws regulating the diminution and the disposition of the muscular current are the same as those of muscular irritability. Between these two physiologists, however, there is this difference, that Du Bois-Reymond thinks that the cessation of the current takes place at the time a supposed coagulation of the fibrinous liquid of the muscles occurs, producing the so-called cadaveric rigidity; while Brown-Séguard has shown that there is no such thing as this coagulation where cadaveric rigidity supervenes. The latter physiologist has discovered that the muscular current, after having completely disappeared (cadaveric rigidity being fully established), may be reproduced, together with the muscular irritability, when an injection of blood charged with oxygen is made into the arteries of a limb. This experiment he has performed not only on animals, but on the limbs of guillotined men. He found that the more oxygen there is in the blood employed, the quicker the muscular current and irritability return. This fact, with many others discovered by Matteucci and Du Bois-Reymond, shows that the production of the current depends on the nutrition of the muscles, and particularly on the oxidation of their tissues. Prof. Matteucci published many facts to prove that the muscular current is independent of the nervous system; but his experiments are all open to objections. More decisive researches have been made by Brown-Séguard, who has ascertained that in muscles whose nerves have completely and definitively lost their vital properties, currents not only exist during life, but may be reproduced by the influence of injections of oxygenated blood when they have disappeared after death.—Du Bois-Reymond has established as a law that every point in the natural or artificial longitudinal surface of a muscle is positive in relation to every part of its transverse surface, whether natural or artificial; and as the tendons, which are conductors, are in communication with the natural transverse surface, it follows that they are negative as regards this surface. This law signifies that the longitudinal surface of a muscle acts like the positive pole of a pile or galvanic battery, while the transverse surface acts like

the negative pole. According to this important law, when any point of the longitudinal section of a muscle is connected by a conductor with any point of the transverse section, an electric current is established, which is directed in the muscle from the transverse to the longitudinal section. Du Bois-Reymond has discovered that the smallest part of a muscle acts in the same way as the whole of it, except that the strength of the current is less and less powerful as the part is smaller. Each elementary bundle of fibrils in a muscle seems to be like a couple in a galvanic battery, except that the couples represented by these elementary bundles are not able to transmit their current so freely as the couples of a real galvanic battery usually are. Du Bois-Reymond has found that the amount of electricity generated in muscles must be excessively great; but as it is impossible to make an aggregation of all the elementary currents existing in a muscle, we have not a real measure of the quantity of electricity produced in these organs.—We owe to Matteucci the discovery of one of the most important facts concerning animal electricity. He found that when a muscle contracts, if there is a nerve placed upon it leading to another muscle, the latter contracts also. The contraction of this second muscle Matteucci calls induced. To facilitate the understanding of what we have to say on this subject, we will call not only this secondary contraction induced, but also the muscle that exhibits it, and we will call the first contraction and the muscle in which it takes place inducing. Matteucci had a great deal of trouble in trying to explain this induced or secondary contraction; his latest view was that it results from a galvanic discharge from the inducing muscle on the nerve of the induced one. Du Bois-Reymond, who has carefully examined the circumstances of this fact, explains it otherwise. He supposes that the current of the inducing muscle passes through the nerve of the induced one, and that when the inducing muscle is set in contraction, the current diminishes, and, as any diminution of a continuous current passing through a nerve is a cause of contraction for the muscle which it animates, it results that the induced muscle contracts. It is known that when a continuous current passes through a nerve there is a contraction in the muscle which it enters in the beginning of the passage and on its cessation, and also when there is any change in its strength.* It is to this last condition that the induced contraction is attributed by Du Bois-Reymond, but, if he were right, there should be a contraction in the induced muscle at the time we put its nerve on the inducing one, and also at the time we take it away; but unfortunately for the theory, there is no contraction in these cases, except in peculiar circumstances. We must therefore consider the theory of the distinguished German physiologist as not sufficiently grounded.—Whatever may be the cause of the

irritation of the nerve of the induced muscle, it is certain that when the inducing one contracts this motor nerve is irritated; the same thing takes place, as Matteucci and Brown-Séquard observe, when an excitor or a sensitive nerve instead of a motor is placed upon the inducing muscle; the irritation then causes either a reflex movement or a pain. Brown-Séquard has been led by many experiments to conclude that the irritation of sensitive nerves by the contraction of inducing muscles has a great share in many important physiological and pathological phenomena. Every one knows that, except when we look at the parts of our body which we move voluntarily, we direct our movements almost entirely according to the sensations that we receive from our contracting muscles. These sensations have been shown by this physiologist to be chiefly due to the induced irritation of the sensitive nerves at the time the muscles contract. The muscular sense of Sir Charles Bell, or the guiding sensations of Prof. Carpenter, are thus obtained, and so it is with the measure of the distance of objects when looked at with both eyes; the state of our ocular muscles teaches us the distance, and they do it by the irritation they induce in nerves while contracting. According to Brown-Séquard, the pain of cramps, that of the contractions of the uterus in parturition, that of the spasm of the sphincters, &c., depends upon an excessive induced irritation of the sensitive nerves in consequence of muscular contractions. Among the other proofs adduced by him in support of his view that muscular contractions, normal or pathological, induce irritations in their sensitive nerve fibres, probably by a galvanic discharge, and exactly as an inducing muscle irritates a motor nerve placed upon it, the following are the most important: He has found that it is electrically just the same thing for the intensity of the irritation of the motor nerve lying upon an inducing muscle, and for the intensity of pain in a case of spasm of the sphincter of the anus, and in a case of contraction of the anterior muscles of the thigh. In these three circumstances, viz., the experiment with the motor nerve, and the two pathological cases in man, we observe: 1, that there is no irritation or no pain if the inducing muscle has no resistance to overcome when it contracts (it is so after the section of the muscle or of its tendon); 2, that the irritation or the pain increases when the inducing muscle is extended. The known facts that the pain due to the spasm of the sphincter of the anus disappears when it is divided, and that the section of a tendon of a contracted muscle causes the cessation of pain, had not hitherto received any explanation. The researches of Brown-Séquard render now very easy the understanding of the mode in which these facts are produced.—With the help of his very sensitive galvanometer, Du Bois-Reymond has been able to prove that the galvanic currents of muscles

in man may be rendered evident during a voluntary movement. If the two electrodes of the galvanometer are in communication, one with one hand and the other with the other hand of a man, and if a voluntary movement is made by one of the arms, there is at once a deviation of the needle of the instrument, indicating the passage of a galvanic current. According to the discoverer of this important fact, at the time of the contraction of the muscles of one arm, the current which existed there, and which was neutralized by a current of equal strength in the other arm, becomes diminished, and therefore the surplus of the other passes out and deflects the needle of the instrument.—Du Bois-Reymond has discovered that nerves are, like muscles, able to afford galvanic currents. The principal law concerning these currents is the same as that of the muscular currents. The direction of the galvanic current of the nerves is from their interior to their exterior, just as it is with the muscles. From all his experiments on the electro-motive power of muscles and nerves, the following conclusions may be drawn: 1. The muscles and nerves, including the brain and the spinal cord, are endowed during life with an electro-motive power. 2. This electro-motive power acts according to a definite law, which is the same in the nerves and muscles, and may be briefly stated as the law of the antagonism of the longitudinal and transverse section; the longitudinal surface being positive, and the transverse section negative. 3. As the nerves have no natural transverse section, their electro-motive power when they are in a state of rest cannot be made apparent unless they have previously been divided. 4. The muscles, having two natural transverse sections, may show their electro-motive power without being divided. However, the electro-motive power of the undissected muscles is often more or less concealed by the contrary action of a layer situated on the natural transverse section, which Du Bois-Reymond calls the *parelectronic layer*. The contrary electro-motive power of this layer may be increased by cooling the animal. 5. Every minute particle of the nerves and muscles acts according to the same law as the whole nerve or muscle. 6. The currents which the nerves and muscles produce in circuits of which they form a part, must be considered only as derived portions of incomparably more intense currents circulating in the interior of the nerves and muscles around their ultimate particles. 7. The electro-motive power lasts after death, or, in dissected nerves and muscles, after separation from the body of the animal, as long as the excitability of the nervous and muscular fibres; whether these fibres are permitted to die gradually from the cessation of the conditions necessary to the support of life, or whether they are suddenly deprived of their vital properties, by heat, chemical means, &c. 8. We may add that, according to Brown-Séquard, the electro-mo-

tive power, at least in muscles, after it has disappeared naturally after death, may be reproduced with the other vital properties by the influence of injections of oxygenated blood. 9. In the different contractile tissues the electro-motive power is always proportioned to the mechanical power of the tissue. 10. Other animal tissues may produce electro-motive action; but it is neither so strong as the action of the nerves and muscles, nor so regular; nor does it vanish with the vital properties of the tissues; nor does it, lastly, undergo those sudden variations of intensity and direction, which may be thus briefly stated: 11. The galvanic current in muscles when in the act of contraction, and in nerves when conveying motion or sensation, undergoes a sudden and great diminution of its intensity. (We have said above that there is some reason to doubt the accuracy of this law as regards muscles.) 12. Muscles inactive from the contrary action of the *parelectronic layer*, when contracting, become active in the opposite direction to that which muscles in a state of rest exhibit. Hence it must be concluded that the electro-motive force of the *parelectronic layer* remains constant in the act of contraction. 13. If any part of a nerve is submitted to the action of a permanent current, the nerve in its whole extent suddenly undergoes a material change in its internal constitution, which disappears on breaking the circuit as suddenly as it came on. 14. The electrical phenomena of motor and sensitive nerves are identical. Both classes of nerves transmit irritation in both directions. We will merely say in addition to these laws, that, in examining who was right between Galvani and Volta, we find that they were both in some points right, and in some others wrong. Galvani was right in saying that there is an animal electricity, and Volta was right in looking at the heterogeneity of metals as a source of electricity; and had he extended his views to the living tissues, he would have found that there also, as in metals, where there are two heterogenic particles in contact one with the other, a galvanic current is generated. II. *The production of static electricity in animals.* A constant production of this kind of electricity cannot be doubted; but animals and men being in free communication with the earth, it is rarely possible to ascertain the presence of this electricity. But when the body of a man is insulated he may affect the electrometer. If two men are insulated, as it often occurs that they are charged with different electricities, there is when they touch each other a peculiar crackling, and sometimes a spark, announcing the combination of the vitreous and the resinous electricity. In dry weather many persons may hear the sound and see the light resulting from a combination, when they suddenly pull off the articles of dress in contact with their skin. Dr. Schneider mentions a Capuchin friar who, on removing his cowl, used to perceive a number of shining,

crackling sparks passing from his scalp. But it is in the United States that the most interesting fact concerning the production of static electricity has been observed. It was in a lady, who for many months was in an electrical state so different from that of surrounding bodies, that, whenever she was but slightly insulated by a carpet or other non-conducting medium, sparks would pass between her person and any object she approached; when she was most favorably circumstanced, four sparks per minute would pass from her finger to the brass ball of the stove at the distance of $1\frac{1}{2}$ inch. Sometimes the electricity thus developed is sufficient to light the gas from an ordinary burner. From the pain which accompanied the passage of the sparks, the lady's condition was a source of much discomfort to her. The circumstances which appeared most favorable to the production of electricity were an atmosphere of 80° F., tranquillity of mind, and social enjoyment; while a low temperature and depressing emotions diminished it in a corresponding degree. The phenomenon was first noticed during the occurrence of an aurora borealis; and though its appearance was sudden, its departure was gradual. Articles of dress had no influence upon its intensity.

ANIMAL HEAT, the heat produced in the interior of animal bodies by the nutritive changes going on in the blood and the tissues. Living animals, as a general rule, if not invariably, have the power of generating heat within their own bodies. The proof of this is, that in many of them the temperature of the body is habitually above that of the surrounding atmosphere or water in which they live. Thus the temperature of the porpoise has been found to be 99.5° F., and that of the seal 104° . The temperature of the human body, and that of the quadrupeds generally, is about 100° ; while that of many of the birds is 105° , 110° , or even 111° . As this temperature is maintained at or about the same standard, though that of the external atmosphere may be much lower, and as the animal is consequently losing heat incessantly by radiation and conduction, it is evident that there is a constant supply from an internal source by which the external loss is made good. In man and in all the higher animals, namely, birds and mammals, this internal heat is very active; so much so that their higher temperature is easily distinguished both by the touch and the thermometer, and is kept at almost a uniform standard whatever may be the external variations. These are therefore called the warm-blooded animals. In reptiles and fishes, on the other hand, the production of heat is less active; their temperature is habitually lower than our own, so that they feel cool to the touch; and it varies so little from that of the surrounding media that greater care is requisite to distinguish it, even by the thermometer. They are accordingly distinguished as the cold-blooded animals. Animal heat is generated, however, even in these

species, as is demonstrated by exact observation. Thus the temperature of a frog has been found to be 48° when immersed in water at 44.4° ; that of a serpent 88.4° , in air at 81.5° ; that of a tortoise 84° , in air at 79.5° ; and that of a fish from 1.7° to 2.5° above that of the surrounding water. In the invertebrate animals, the appreciation of their temperature by the thermometer has been found more difficult, since, on account of their small size, the radiating external surface is greater in proportion to the mass of heat-producing tissue within; and the heat thus generated is almost as rapidly dissipated. This difficulty, however, has been overcome in the case of insects by experimenting upon a large number collected in a small space. Thus Mr. Newport found that when the temperature of the external atmosphere was 34.5° , that of the interior of a hive of bees was 48.5° ; and that if the insects were thrown into a state of active excitement by rapping on the hive, it would rise to 102° .—The heat thus produced in the interior of the body is not exactly the same in degree in every part. It is generated either in the blood itself or in the substance of the internal organs, or most probably in both. At all events, the blood acquires during its circulation through different organs slightly different degrees of warmth. Thus Claude Bernard has found, by introducing the bulb of a delicate thermometer into the vessels of a living dog, that the temperature of the blood in the abdominal aorta varied from 99.5° to 105.5° ; in the portal vein, from 100° to 106° ; and in the hepatic vein, from 101° to 106.8° . The warmest blood in the body, on the average, was that of the hepatic vein, which had passed through two successive capillary circulations, namely, that of the intestines and that of the liver, since leaving the arterial system. On the other hand, while passing through an organ in which it is exposed to the influence of air and evaporation, the blood diminishes somewhat in temperature. Thus, in passing through the lungs it was found to have lost sometimes a little less and sometimes a little more than $\frac{1}{3}^{\circ}$ F. For the same reason, the temperature of the skin is habitually a little lower than that of the internal organs. If the bulb of a thermometer be taken between the fingers of the closed hand, it will rise only to 90° or 95° ; in the axilla, carefully protected from the air, it will stand at 98° ; while under the tongue, and in contact only with the vascular mucous membrane, it will reach 100° . In the external parts of the body, therefore, which are especially exposed to the influence of the outer air, the temperature may vary considerably. Especially the thinner parts, with a comparatively greater extent of surface, feel this variation in a marked degree, and may thus be affected with a local depression of temperature. On a very cold day the ends of the fingers, the nose, the ears, &c., may be cooled down very considerably, and in some instances may be even

congealed and destroyed, without affecting sensibly the general system. But if the cold be so intense and long continued as to depress the general temperature of the blood and the internal organs, the system at large begins to feel its effects, and the vital powers yield to its influence. A numbing effect is produced, followed by a difficulty of muscular exertion, a confusion of mind, drowsiness, and insensibility; and death takes place long before the body as a whole is actually congealed. Thus the maintenance of the internal temperature at or near the natural standard is a condition necessary to life. Experiments upon the warm-blooded animals have shown that in them, as a general rule, death is produced when the temperature of the blood is reduced to about 80° . The vital changes necessary to existence cannot go on below this point. On the other hand, the animal temperature may rise above the natural standard. There is no doubt that an increase of heat is produced in the muscular tissue during the contraction of these organs. We have already noticed the rise of temperature observed by Mr. Newport in a hive of bees when the insects were excited to activity. Becquerel and Breschet found the temperature of the biceps muscle of a man raised 1.8° by active contraction and relaxation continued for several minutes; and Matteucci observed an increase of 1° in the muscle of a frog separated from the body and artificially excited to contraction. It is a matter of common observation that a general sensation of unusual warmth follows any active muscular exertion. Not only is the temperature of the muscular system itself raised, but the rapidity of the circulation is accelerated, a larger quantity of warm blood is brought to the skin in a given time, and the sensitive integument thus feels the increased temperature. No doubt it is owing to this fact that active muscular exercise is itself a protection against external cold. An unusual degree of heat in the atmosphere also tends indirectly to raise the temperature of the body; for if the internal production of heat be the same, and its external loss by contact with the atmosphere be diminished, of course the actual temperature of the body would rise in consequence. A provision is made, however, against allowing this increase of temperature, whether from muscular exertion or external heat, to reach too high a point. This provision is the cutaneous perspiration. Anything which raises the bodily heat above the natural standard excites the circulation through the skin, and increases the quantity of perspiration poured out upon its surface. This fluid, by its evaporation, uses up or renders latent a portion of the heat, and thus reduces the skin and the blood circulating through it to its natural temperature. The body therefore can be exposed to a very high external temperature without itself rising above its natural standard, provided the perspiration be free and its evaporation unimpeded. If the perspiration be checked, how-

ever, or if its evaporation be prevented by exposure to hot water, or hot air loaded with moisture, the temperature of the body rises, and death soon takes place. The experiments of Magendie and others have shown that in the higher animals life is destroyed when the blood generally has become heated 10° or 13° above the natural standard. Animals therefore have a natural internal temperature, which is essential to the performance of the vital functions, and which cannot be either raised or lowered to any considerable extent without producing death.—With regard to the precise mode in which animal heat is generated, and its exact chemical conditions, opinions are not entirely agreed. Many physiologists have entertained and still accept the belief that it is due to an oxidation or combustion of the elements of the blood and tissues by the oxygen absorbed in respiration. The grounds for this doctrine are as follows: 1. The most common and ready method by which heat is generated artificially is the combustion of substances, like wood and coal, which are rich in carbon. The rapid oxidation of these substances, which requires a free access of air, causes a great development of heat, and at the same time uses up the oxygen of the atmosphere, and produces as a result carbonic acid. The consumption of fuel, the degree of heat produced, and the quantities of oxygen absorbed and carbonic acid liberated, are all in direct ratio to each other. The process may go on rapidly or slowly; but in either case the relations of quantity remain the same. If the oxidation be rapid, as in a furnace or open fireplace with a strong draught, the fuel is soon consumed and a large quantity of heat is produced in a given time. If the process be retarded, as in a close stove with a limited or gradual admission of air, the consumption of fuel is slow, and the heat, less intense at any particular moment, is continued for a proportionally longer time. But in both instances, for the entire amount of heat which has been generated, there are the same quantities of fuel consumed, of oxygen absorbed, and of carbonic acid produced. 2. In the animal body the absorption of oxygen and the exhalation of carbonic acid are the most striking and constant of all the phenomena of nutrition. At the same time heat is evolved, as in the case of artificial combustion; and it is very natural to connect the two sets of phenomena with each other. Furthermore, as in artificial combustion, the elevation of temperature in different animals corresponds very closely with the activity of respiration and the quantity of the two gases inspired and exhaled. These considerations have led to the adoption of the theory, at once intelligible and comprehensive, which attributes the production of animal heat to the direct oxidation or combustion of the carbonaceous ingredients of the food and tissues.—On the other hand, there are certain facts which are less favorable to the above theory. 1. In the first place, though the combustion of carbonaceous

matter happens to be the most familiar and useful of the artificial means for producing heat, it is by no means the only one which will have that effect. A great variety of both physical and chemical changes, other than oxidation, are attended with an elevation of temperature, often of a very active kind; as in the ordinary slaking of lime, where a boiling temperature may be reached in a few minutes by the simple combination of water with the alkali, which already contains the oxygen it is capable of absorbing. A great variety of chemical and physical changes are constantly going on in the process of nutrition, varying in their character in the different organs; and of their details we are in many cases still ignorant. As we have seen that animal heat is produced as a local phenomenon in the different organs, it may be the result of these combined changes, which vary in character in different parts of the body. 2. The first absorption of oxygen by the blood, which takes place in the lungs, is not accompanied by any very marked elevation of temperature. This elevation, if it exist at all, is not sufficient to compensate for the cooling effect of the air and exhalation in the pulmonary cavities; for we have seen that in the living animal the blood has been found by experiment to lose slightly instead of gaining in temperature while passing through the lungs. The oxygen is here taken up by the red blood globules, and thence distributed to the tissues; but it is doubtful whether its subsequent transfer to the ingredients of the tissues has any more the character of an active combustion than its first absorption by the blood. Some physiologists regard oxygen as a kind of food which must be supplied to the body with great regularity and constancy, and which is destined to become a constituent part of the tissues very much in the same manner as other nutritive elements. 3. The production of carbonic acid in the interior of the body is directly due, not to a combination, but to a decomposition of the ingredients of the tissues. Carbonic acid may be generated at any time in either of two ways: by the immediate combination of oxygen with carbon, as in the combustion of charcoal; or by the decomposition of another body still more compound in its nature, as in the decomposition of carbonate of lime by an acid, or the decomposition of sugar in fermentation. In both these latter cases carbonic acid is evolved without any direct oxidation taking place; and the process will go on accordingly without the access of oxygen or atmospheric air. In the animal body it is by such a process of decomposition that carbonic acid is produced; and the proof of this is, that if the fresh muscles of a frog, or the living animal itself, be enclosed in an atmosphere of hydrogen or nitrogen, or even in a vacuum, they will still for a considerable period continue to exhale carbonic acid. This has been fully shown by the experiments of Marchand. 4. While it is true that the development of animal

heat is in proportion to the consumption of oxygen and the exhalation of carbonic acid, this is also true of most if not all the other substances consumed and eliminated by the living body. An abundant production of warmth coincides with a general vigor and activity of all the animal functions, with muscular exertion, capacity of endurance, and a liberal consumption of both the nitrogenous and non-nitrogenous elements of food. We cannot safely attribute the heat-producing power exclusively to one or the other class of alimentary substances; for while fat and albuminous matters are both consumed in large quantities in cold climates, on the other hand starchy materials form a considerable proportion of the food in warm weather and in tropical climates. In point of fact, oxygen and carbonic acid are two substances which enter and are discharged from the system by the same organ, the lungs; but there is not necessarily any direct relation between them, except that oxygen is one of the nutritious substances essential to the body, and carbonic acid is excrementitious.

ANIMAL MAGNETISM, or Mesmerism, an influence analogous to terrestrial and metallic magnetism, supposed to reside in animal bodies and to be capable of transmission from one to another. It was first brought into notice in Germany in 1775 by Mesmer, a native of Swabia, who had graduated in medicine at Vienna nine years before, and had written as his inaugural thesis a treatise on "The Influence of the Planets on the Human Body." He regarded the new force, which he said could be exerted by one living organism upon another, as a means of alleviating or curing disease. Maximilian Hell, a professor of astronomy at Vienna, had made some suggestions to Mesmer a few years earlier as to the possibility of producing an effect on the human body by magnetism, and he soon claimed to be the discoverer of the new influence. Mesmer declared that the effects he produced were those of animal magnetism, capable of transmission without his touching the body of the patient, while Hell's theory, he affirmed, had made necessary the actual contact of the patient with a metallic magnet. The disputes to which this rivalry gave rise, together with various accusations of imposture, caused Mesmer to receive a warning from the government. He left Vienna, and in 1778 transferred his residence to Paris. Here he appears to have been from the first regarded with dislike, or at least with suspicion, by the medical profession, but with great favor by the general public. He received at his house patients suffering from various diseases, and performed upon them many reputed cures by the influence of the magnetic fluid. His method was to seat himself in front of the patient, with his eyes steadily fixed upon him, and to perform with the hands a few preliminary manipulations about the epigastrium and hypochondrium in order to establish between them what he called the "magnetic relation." He then

proceeded to operate upon the diseased part by touching it with the right hand on one side and the left on the other, and performing certain circular or vibratory movements with the fingers which were left free; an essential condition being that actual contact should be kept up on the two opposite sides in order that the magnetic influence might circulate, passing into the body of the patient on one side and out again on the other. His idea with regard to the nature of the influence termed animal magnetism may be best conveyed in his own words, as contained in a set of so-called "propositions" or "assertions," in a volume published by him in 1779 and entitled *Mémoire sur la découverte du magnétisme animale*. The most important of these propositions are as follows: 1. "There exists a mutual influence between the celestial bodies, the earth, and animated beings." 2. "This reciprocal action is regulated by mechanical laws which up to the present time have been unknown." 3. "Animal bodies are susceptible to the influence of this agent; and they are affected by it on account of its disseminating itself through the substance of the nerves." In cases where the body was affected by some disorder which pervaded all parts of the system, Mesmer was in the habit of magnetizing his patients with long and wide passes, made from a distance, either with the open hands or with the aid of a short-rod or wand of glass or steel. His success with the public, however, and the number of patients who presented themselves, increased so rapidly that he could no longer give to each one the personal attention rendered necessary by this method of practice, and a new one was adopted which soon became the main feature of the magnetic system, and was in fact the principle from which mesmerism, or animal magnetism as practised by Mesmer, acquired its greatest reputation and popularity. This was the "magnetic tub," about a foot and a half high and six feet in diameter, placed in the centre of a spacious apartment. This tub was filled with water up to a certain level, and its bottom covered with a mixture of iron filings and broken glass. Around its outer circumference were ranged a series of bottles with their necks looking inward toward the centre, and around its centre another set of bottles with their necks looking outward. The whole tub was surmounted by a wooden cover pierced with a number of small holes; and through these holes were inserted an equal number of glass or metallic rods bent at right angles, the inner ends of which dipped beneath the surface of the water, while the outer portions radiated horizontally in every direction, and were held in contact with the bodies of the patients, arranged in concentric circles round the tub. Thus a large number could be subjected at the same time to the magnetic influence. The tub was a sort of reservoir in which the magnetic force was condensed, and from which it radiated in continuous currents through the bodies

of the patients. Its circulation was secured by means of a long cord, attached by one extremity to the tub, and passed in successive loops round the waist of each person, the magnetizer himself forming one link in this continuous chain of living bodies. Thus the magnetism, radiating from the tub by the metallic rods, returned again to it by means of the cord, and so continued its course in a closed circuit without ever becoming exhausted. The more susceptible of the patients soon felt a nervous influence pervading the affected parts, or even their whole bodies. This often became so intensified as to produce irregularity of respiration, and, especially among the female patients, sobs and laughter of a hysterical nature, exaltation of the sensibilities, partial unconsciousness, and even convulsions and a kind of maniacal delirium. These effects, however, lasted but for a time after the patient was removed from the magnetic circle, and resulted in many cases, according to the assertions of Mesmer and his friends, in the relief or cure of diseases previously regarded as hopeless. The receipts of Mesmer from the patients resorting to his establishment were said at one time to amount to nearly 100,000 francs a year. His system had indeed become so popular that he ventured to address a note to the French government, stating that he had discovered an agent by which most of the diseases of the human frame could be cured, and requesting the grant of a certain château and adjoining lands as a reward for his discovery, and as a place for the establishment of a great healing institute. The government refused his request, but offered him a yearly pension of 20,000 livres, and a certain sum for the establishment of a hospital, on condition that he should teach his doctrines to some persons, of whom three should be selected by the government. This offer he rejected; and his friends, desirous of giving him some lasting pecuniary reward for his discoveries, proposed that classes should be formed of pupils whom he should instruct in animal magnetism. Each pupil should pay 100 livres as tuition fee, and bind himself not to teach others. These classes were formed, and they paid him in all 340,000 livres. Among those who subscribed themselves as pupils were Lafayette, D'Esprémenil, the marquis de Puysegur, and Dr. D'Eslon. D'Eslon was a man of much influence, and held the post of physician to the king's brother. He took great interest in animal magnetism, used it in his practice, and made a large fortune by its means. In 1784 the French government ordered the medical faculty of Paris to investigate Mesmer's theory, and make a report upon it. Under this order a commission was appointed, consisting of Benjamin Franklin (at that time minister to France from the United States), Lavoisier, Bory, Bailly, Majault, Sallin, D'Arcet, Guillotin, and Le Roy. Mesmer refused to appear before them, but D'Eslon took his place, made himself the advocate of the new doctrine, and tried a great

number of experiments before them. In their report to the government the commissioners say that, "in regard to the existence and the utility of animal magnetism, they have come to the unanimous conclusion that there is no proof of the existence of the animal magnetic fluid; that this fluid, having no existence, is consequently without utility; and that the violent effects which are to be observed in the public practice of magnetism are due to the manipulations, to the excitement of the imagination, and to that sort of mechanical imitation which leads us to repeat anything which produces an impression upon the senses." The special report of the committee of the academy of sciences, consisting of Franklin, Le Roy, Bory, Lavoisier, and Bailly, and made to the academy itself, concludes as follows: "Magnetism, accordingly, will not have been altogether valueless for the philosophy which pronounces its condemnation; it is one more fact to be recorded in the history of the errors of the human mind, and an important experiment upon the power of the imagination." (*Histoire de l'Académie royale des sciences*, 1784, p. 15.) This report of the commission, together with a previous quarrel in regard to money matters between Mesmer and his partisans, seems to have rapidly diminished the prosperity and esteem which he had enjoyed in Paris. He left that city in 1785, and passed the rest of his life in retirement in Switzerland, in the possession of considerable wealth acquired from his former magnetic practice.—About the time of Mesmer's retirement from Paris, animal magnetism entered upon a new phase of development, by the discovery by the marquis de Puységur of the magnetic sleep, or somnambulism, which afterward became still further developed by the addition of clairvoyance. It is under this title that the most surprising phenomena of animal magnetism have been exhibited during the present century. A magnetic clairvoyant is a person who, having been thrown into the somnambulist condition by the manipulations of the magnetizer, becomes possessed of extraordinary powers of sense and perception. The term clairvoyant designates the power which is claimed for these persons of seeing distinctly through the substance of opaque objects. Thus a clairvoyant, it is said, can read a book unopened, or a letter which is enclosed in a solid wooden box. He can do this as well as with his eyes closed or bandaged as if they were open and uncovered. Sometimes the sense of sight, or a faculty capable of perceiving things which the normal man perceives only by means of the organ of vision, seems seated in the forehead, in the backhead, in the fingers, or in the knuckles of the hand. It is asserted that the clairvoyant can hear also without using his ears, and with more acuteness than can others in the waking state using their ears. Sometimes the sense of hearing appears to have its seat at the pit of the stomach, and the clairvoyant hears no sounds except those made at

his breast. The senses of taste, touch, and smell are ordinarily inactive. But while insensible to impressions upon his own nerves, he feels all those which are experienced by his magnetizer; and if the latter be pinched, the clairvoyant winces, as though he felt the pain at the corresponding part of his own body. He is governed by the will of the magnetizer; whatever the latter orders him to do, he does; and this order is understood and obeyed, even if not spoken, but merely thought. As the theory of these alleged phenomena was gradually developed, mesmerism again rose into some degree of favor. M. Deluze, assistant secretary and naturalist of the Jardin des Plantes, published in 1813 a favorable "Critical History of Animal Magnetism;" and other friendly publications followed rapidly in France and Germany. Several able German physiologists spoke of the new agent as worthy of attention. Well conducted magazines were established to propagate its principles. The Prussian government took notice of it in 1817, so far as to order that none save physicians should practise it; and in the following year the academy of sciences of Berlin offered a prize for the best treatise on the subject, but this offer was subsequently withdrawn. Ennemoser, Kluge, Kieser, Wolfarth, and Nees von Esenbeck defended mesmerism in books and magazines before the German public, and Delenze kept the subject before France by publishing a number of works. In 1825, Dr. Foissac, a young physician and an enthusiastic believer in animal magnetism, demanded of the royal academy of medicine in Paris that another commissioner should be appointed, and another investigation made. The academy consented and appointed a commission of five members to conduct the inquiry. Their report, not made till 1831, while it did not concede by any means all that the believers in the new force claimed, was in general favorable to the theory of its existence and effects; and although not regularly adopted by the academy, or printed as a part of its formal memoirs, it gave a powerful impulse to the investigation of mesmerism, and extended it into Britain and America, where it had been almost unknown before. In 1833 J. C. Colquhoun published in English a translation of the report with remarks; in 1836 he published an original work on the same subject, entitled *Isis Revelata*. In 1837 the subject was again taken up by the academy. A committee of nine was appointed, among whom were Roux, Botillard, and Cloquet, who tested in several seasons the phenomena exhibited by a reputed clairvoyant. Their report, made Aug. 17, 1837, detailed all the particulars of their investigations, and expressed the results as follows: "The facts which had been promised by M. Berna (the magnetizer) as conclusive, and as adapted to throw light on physiological and therapeutical questions, are certainly not conclusive in favor of the doctrine of animal magnetism, and have nothing in common with either physiology or

therapies." This report was adopted by the academy Sept. 5, 1837. In the same month M. Burdin, a member of the academy, made a standing offer of 3,000 francs to whoever within two years should produce a clairvoyant able to read without the use of the light, the eyes, or the touch. The conditions of the trial were afterward modified so that the paper to be read might be illuminated, provided the eyes of the clairvoyant were properly covered, and the sense of touch might be used as an aid, but with a smooth glass surface covering the object to be examined. The time during which the prize was to remain open was also extended to three years. The money was deposited with a notary subject to the order of the academy, and a committee appointed to supervise the experiments. Several clairvoyants appeared as contestants for the prize at various times, but the committee in each case reported their complete failure.—About 1840 a new and prominent student of animal magnetism appeared in the person of Mr. Braid of Manchester, England, who discovered that he could produce sleep in most persons whom he tried, by ordering them to look steadily at some small object about a foot from the eyes, and above their level. He gave the name of "hypnotism" to the sleep and somnambulism thus produced, and styled his theory for the explanation of the phenomena "neurypnology." The principles discovered by him were applied by other persons in various ways, and variously styled "biology," "electro-biology," &c. All the phenomena produced under these different names are substantially mesmeric. Mr. Braid had no faith in clairvoyance proper; but he admitted an "exaltation of the senses" in the mesmeric and hypnotic states, giving a delicacy of perception, and sometimes a perspicacity of reasoning, exceeding that of the normal state. These views were sanctioned by Dr. William B. Carpenter in his "Human Physiology."—Recently there has been no special change in the doctrine of clairvoyance, except that it has become somewhat closely connected with that of spiritualism. While the members of the medical profession, with few exceptions, have always opposed the claims of mesmerism, these have nevertheless found supporters in many men of learning and eminence; among them, besides those already mentioned, are Laplace, Cuvier, Agassiz, Hufeland, Sir William Hamilton, Dr. Herbert Mayo, and Prof. Edward Hitechoek. For information in regard to the theories of its advocates, see Deleuze's "Practical Instruction in Mesmerism;" "Letters on Animal Magnetism," by Prof. William Gregory; "Mesmerism, its History, Phenomena, and Practice," by William Lang; "Facts in Mesmerism," by the Rev. Chauncey Hare Townshend; "Truth in Popular Superstitions," by Dr. Herbert Mayo; and "Practical Instruction in Animal Magnetism," by Dr. Alphonse Teste.

ANIME (Fr., animated), a resin supposed to be derived from the *hymenaea courbaril* of South

America. It exudes from wounds in the bark, and collects between the principal roots. This resin is soft and sticky, and melts easily, diffusing white fumes and a very pleasant odor. Insects are generally entrapped in such numbers in it, that it is said to well merit its name of animated. The Brazilians use it internally in diseases of the lungs. It was formerly employed in the composition of ointments and plasters, but at present its only use is for varnishes and incense.

ANISE SEED, the fruit of the *pimpinella anisum*, a native of Europe and Africa. It is extensively employed as a carminative medicine, and for the purpose of flavoring liqueurs or medicines. It yields an aromatic oil both by distillation and expression, which is used

Anise (*Pimpinella anisum*).

for the same purposes as the seed, and is also a favorite article with vermin-killers, who employ it to disguise the scent of poisonous baits. The anise-seed cordial of the shops is a compound of alcohol, anise seed, and angelica. The plant is cultivated in Malta and Spain, and grows spontaneously in Egypt and the islands of the Grecian Archipelago, especially Scio. The genus *pimpinella* belongs to the umbelliferous tribes of plants inhabiting meadows and mountains in Europe and Africa.

ANJOU, an ancient province of N. W. France, chiefly constituting the present department of Maine-et-Loire, with Angers for its capital. In the time of the Romans it was inhabited by the Andegavi. During the Frankish and feudal eras its counts played an important part in European history. The eldest branch of the family traced its descent to the days of Charles the Bald in the 9th century, and the younger branches to those of Louis VIII. and XI., in the 13th. Among the eminent counts of Anjou, those of the name of Foulques or Fulk were distinguished as crusaders, especially Foulques V., who in 1131 succeeded his father-in-law Baldwin II. as king of Jerusalem. His son Geoffrey, surnamed Plantagenet, became

through his marriage (1127) with the empress Matilda the father of Henry II. of England. Charles, brother of St. Louis, commonly called Charles of Anjou (born about 1220), a brave crusader, heir to Anjou and Provence, became the founder of the younger branch which reigned over the Two Sicilies. In 1356 Anjou was made a duchy. Louis, son of King John II., was the first duke, and ancestor of the "good King René of Anjou." The last of this branch, Charles IV., bequeathed the duchy to Louis XI., who permanently annexed it to France (1483). Since that time Anjou has merely given honorary titles to Bourbon princes. Among them was Francois, fourth son of Henry II. and Catharine de' Medici, duke of Alençon, afterward duke of Anjou (born in 1554). He was famous for his zeal in favor of the Huguenots, and his opposition in the Netherlands to Philip II. After having been for a short time acknowledged by the Netherlanders as ruler under the title of duke of Brabant (1582), they expelled him on account of his autocratic measures. He was one of the rejected suitors of Queen Elizabeth. Several descendants of Louis XIV. bore the title of dukes of Anjou. Louis XV. bore it anterior to that of dauphin; and Phillip V. was known in France under the same title before he became king of Spain, at the beginning of the 18th century.

ANJOU, Margaret of. See MARGARET.

ANKLAM, an old town of Germany, in the Prussian province of Pomerania, on the river Peene, 6 m. from its mouth in the Stettin-Haff, 45 m. N. W. of Stettin, and 91 m. by railway N. of Berlin; pop., including the three suburbs, in 1871, 10,739. It has an active trade.

ANKWITZ, Mikolaj, count, a Polish politician, executed in 1794. He was ambassador at Copenhagen, and deputy to the diet from Cracow. In the diet of Grodno, which was forced to sanction the second dismemberment of Poland, he played a prominent part; and when the treaty consummating it was concluded with Russia, he was deputed to sign it on behalf of Poland, July 23, 1793. Immediately afterward a salary of \$13,000 was conferred upon Ankwitz by the Russian government, with the appointment of president of the council. When these facts became known, the rage of the people knew no bounds. On April 18, 1794, soon after the breaking out of the revolution of which Kosciuszko became the leader, he was accused of treason, and his correspondence was seized, which established his guilt. He was hanged, and buried in the felons' graveyard.

ANNA CARLOVNA, grand duchess of Russia, originally called Elizabeth Catharine Christina, daughter of Charles Louis, prince of Mecklenburg, and Catharina Ivanovna, daughter of the eldest brother of Peter the Great, born in 1718, died March 18, 1746. She was a niece of the empress Anna Ivanovna. In 1739 she married Anthony Ulrick, duke of Brunswick-Wolfenbützel. They had in 1740 a son, Ivan, whom the empress Anna designed as heir to the Rus-

sian crown, appointing Biron regent. After the death of the empress the same year, Anna Carlovna overthrew the regency of Biron and took affairs into her own hands, declaring herself grand duchess. A year later (December, 1741) she was overthrown by Elizabeth, daughter of Peter the Great, who was declared empress. The boy Ivan was shut up in the fortress of Schlüsselburg, where he perished. Anna, her husband, and a daughter were sent to Kholmogory, a small town on an island in the Dwina, near the White sea, where she died.

ANNA COMIENA, daughter of Alexis Comnenus, emperor of Constantinople, and the empress Irene, born Dec. 1, 1083, died in 1148. She was married to Nicephorus Bryennius, a Greek nobleman of distinction, whom she incited after the death of her father, in 1118, to conspire against her brother and seize the sceptre. The conspiracy failed, and Anna and her husband were banished from Constantinople and stripped of most of their property. Anna during her exile composed a biography of her father, which she styled *Alexias*. This work is divided into 19 books, and, though very defective in many respects, is yet of great importance as a history of the period of which it treats. The best edition of the *Alexias* is Schopen's, published at Bonn in 1839.

ANNA IVANOVNA, empress of Russia, born in 1693, died Oct. 28, 1740. She was the daughter of Ivan, the eldest brother of Peter the Great, and married the duke of Courland, who died previous to her ascending the throne. She became empress on the death of Peter II., grandson of Peter the Great, in 1730. Ostermann, the great chancellor, and the then all-powerful princes Dolgoruki facilitated her elevation over the heads of two daughters of Peter the Great, as Anna promised a limitation of the autocracy. But Anna brought from Courland to Moscow her favorite, the former equerry Biron, who prevented her from keeping her promise, exiled the Dolgorukis to Siberia, and ruled absolutely over the empress and the nation. He organized the system of espionage over all classes, officials and private individuals, which with more or less rigor prevailed for more than a century. Anna interfered in the affairs of Poland, in 1733, in favor of Augustus III. against Stanislas Leszezynski, and obliged the Courlanders to choose Biron for their sovereign duke, and on her deathbed named him regent during the minority of her nephew Ivan; but a revolution overthrew him, and he was exiled to Siberia.

ANNABERG, a town of Saxony, in the Erzgebirge, 2,000 feet above sea level, in the district of Zwickau, 19 m. by railway S. of Chemnitz; pop. in 1871, 11,639. The mining, formerly of great importance, has been diverted to other localities, and the government department relating to it was removed in 1856 to Marienberg. Annaberg, however, besides being the seat of various district authorities, continues

to be an important centre for the manufacture of lace and fringes, which latter industry was introduced about 1590 by Protestant refugees from Spanish oppression in Flanders. Crinolines are also made here to the extent of over 100,000 dozens annually. The town was founded in 1496.

ANNALS (Lat. *annales*, that is, *libri annales*, year books), a concise and unadorned narrative of events, written in the order of time. In the early days of Rome the pontifex maximus kept a record of state affairs, prodigies, and the markets, which, written upon a white tablet, was displayed in some convenient portion of his house to the public inspection. These records were called *annales maximi*, and were written down to the pontificate of Publius Mucius Scaevola, 131 B. C. When the Gauls burned the city, 390 B. C., the greater portion of those previously written were de-

stroyed. Subsequently, other individuals composed portions of Roman history, imitating in style the pontifical annals. The first of these works, which was written by Quintus Fabius Pictor, commenced with the founding of Rome, and came down to the author's own time, during the second Punic war.

ANNAPOLIS, a city of Anne Arundel county, Md., capital of the county and of the state, 28 m. S. by E. of Baltimore, and 40 m. E. by N. of Washington; lat. of the state house, 38° 58' N., lon. 76° 29' W.; pop. in 1860, 3,223 whites and 1,301 colored; in 1870, 5,744, of whom 1,682 were colored. It is beautifully situated on the Severn river, about 2 m. from its junction with the waters of Chesapeake bay. For a long period before Baltimore was at all noted, Annapolis was the seat of wealth, refinement, and extensive trade. It was formerly a port of entry, but has lost its commer-

United States Naval Academy, Annapolis.

cial importance, and is now chiefly distinguished as the seat of the state government and of the United States naval academy. The city is connected with Baltimore and Washington by railroad, and with the former also by regular lines of steamers. The plan of the city bears some resemblance to that of the national capital, all the streets radiating from two points, the state house and the Episcopal church. Its appearance is interesting from its air of quiet seclusion; and the antique look of many of the houses, with their peculiar style of architecture, gives the stranger an impression of some old European town, rather than that of an American city. The state house, standing on an eminence, is a noble and massive structure of brick, with a lofty dome and cupola. It contains the halls of the legislative assembly, as well as the state library and records. St. John's college, founded in 1784, is a state institution. In 1868 there were 10 instructors, 433 gradu-

ates, and about 3,500 volumes in the library. St. Mary's seminary, a Roman Catholic institution, is also situated here. Three weekly papers are published in the city. The naval academy was established in 1845 by the Hon. George Bancroft, then secretary of the navy. Candidates (who must be over 15 and under 18 years of age) are admitted to the institution after passing a thorough physical examination, as well as an examination in the elements of an English education. They remain in the institution four years, under strict discipline and instruction in all the branches of the naval profession, before they are examined for admission into the navy as midshipmen. The academic board is composed of the superintendent of the institution, who must be an officer of the navy, not below the rank of commander; the executive officer, or commandant of midshipmen, with four assistants, who must be either commanders or lieutenants in the

navy, and who discharge the duties of instructors in seamanship, naval tactics, and practical gunnery; and the professors of mathematics, of steam engineering, of astronomy, navigation, and surveying, of natural and experimental philosophy, of field artillery and infantry tactics, of ethics and English studies, including international law, of the French and Spanish languages, and of drawing and draughting. The academic staff consists of the members of the academic board as heads of the different departments, assisted by 64 professors and instructors. The grounds connected with the establishment are extensive, having recently been considerably enlarged. Across College creek 114 acres were added in 1869, and in 1870-71 a large naval hospital was built upon this ground at a cost of over \$150,000. The grounds immediately surrounding the academy contain buildings for recitation and lecture rooms, mess rooms, dormitories, officers' quarters, a philosophical hall and laboratory, and an astronomical observatory. The observatory has an equatorial telescope constructed by Clark of Boston, with a fine achromatic lens of $7\frac{3}{4}$ inches clear aperture, and $9\frac{1}{2}$ feet focal length; an excellent meridian circle by Repsold of Hamburg; and a very complete collection of the minor instruments used by the travelling astronomer, the surveyor, and the navigator. The academy has a carefully selected library of about 15,000 volumes, to which additions are made annually. Fort Severn, to which the grounds formerly pertained, is now enclosed and covered with a roof, and used as a gymnasium and ball room. Two sloops of war are attached to the institution, used during the summer months as practice ships, and for sailing upon an ocean voyage. At the beginning of the academic year 1870 the whole number of midshipmen in the several classes was 253; 68 graduated at the end of the year, and 100 were admitted. During the civil war, the academy was removed to Newport, R. I., but soon after its close was brought back here.—Annapolis was settled in 1649 by puritan refugees from Virginia, under a ruling elder named Durand, and was at first called Providence. The next year Brooke, under a commission from Lord Baltimore, organized the county under its present appellation, and called the settlement Anne Arundel Town in honor of Lady Baltimore. A few years later it was again known as Providence, and was the seat of a Protestant council, disputing the legislative authority with the Catholic council at St. Mary's. The latter was finally abandoned in 1694, and the government was established at the settlement on the Severn, where a town had been regularly laid out and called Annapolis after Queen Anne, who gave it some valuable presents. A city charter was granted in 1708. At the close of the revolution Maryland offered to cede Annapolis to the general government as the federal capital. During the negotiations for a permanent site, it was re-

solved in 1783 that congress should meet alternately at Annapolis and Trenton, the first session to be held at Annapolis. It was at this session that Washington surrendered his commission as commander-in-chief, Dec. 23, 1783.

ANNAPOLIS. I. A W. county of the province of Nova Scotia, Canada, bounded N. W. by the bay of Fundy; area, about 1,700 sq. m.; pop. in 1871, 18,121. The principal river is the Annapolis, which flows S. W. about 60 m., through an expansion called Annapolis basin, to the bay of Fundy. The surface is varied. The elevated ridge of the North mountains extends along the coast, with flanks of excellent soil; the uplands of the valley of Annapolis river are well adapted to fruit culture; and the region S. of the Annapolis valley is broken but generally fertile. There is a valuable bed of iron ore near the Moose and Nietaux rivers. The chief employment of the population is agriculture, and the exports of dairy produce are considerable. II. A town (formerly *Port Royal*), capital of the above-named county, situated on Annapolis basin, in lat. $44^{\circ} 40'$ N., lon. $65^{\circ} 37'$ W., 95 m. W. of Halifax, with which it is connected by railway; pop. 2,127. The basin is a capacious and sheltered harbor, but the entrance, through Annapolis strait, is narrow and difficult. The first European settlement on this part of the coast was made here by De Monts in 1604. Under the name of Port Royal it was the capital of the French colony of Acadia, after the conquest of which by the English in 1710 the name of the town was changed. The capital was removed to Halifax in 1750.

ANN ARBOR, a city of Michigan, capital of Washtenaw county, lying on both sides of Huron river, in lat. $42^{\circ} 15'$ N., lon. $83^{\circ} 43'$ W., 38 m. by railroad W. of Detroit; pop. in 1870, 7,363. The Huron river, and a creek which empties into it from the south, supply valuable water power. There are within the limits of the township 2 woollen mills, 4 flour mills, 5 breweries, 2 factories of agricultural implements, 2 tanneries, 2 printing offices, numerous saw mills, planing mills, and workshops for wood and iron, 10 churches (2 Baptist, 2 Methodist, Catholic, Episcopal, Congregational, Presbyterian, Lutheran, and Unitarian), and 6 school houses, one of which has accommodation for 1,000 pupils. There are numerous fruit gardens, and the streets are thickly planted with shade trees. Two railroads pass through the town, the Michigan Central, E. and W., and the Toledo and Saginaw, N. and S., and the city is the centre of a brisk inland traffic. There are five mineral springs in the city (over one of which has been erected a large water-cure establishment), an opera house, concert halls, and a ladies' library association. Of the resident inhabitants, about one quarter are of German descent, and the German language is taught in the schools. The most important interest of Ann Arbor is the Michigan university. (See MICHIGAN UNI-

VERSITY.) Ann Arbor was settled in 1824, and incorporated as a city in 1851.

ANNATS, or **Annates**, originally certain funds which by ecclesiastical law were paid by a new incumbent of a church living to the pope or bishop. As the name indicates, they amounted to the first year's stipend from the living, and were required in one instalment, but were afterward paid in two. In England they were at first paid to the archbishop of Canterbury; the popes afterward appropriated them. The English parliament in 1532 bestowed them on the crown, but Queen Anne restored them to the church, for the support of the poorer livings, whence they have been called Queen Anne's bounty. In Germany annats are synonymous with the *servitia*, an early form of taxation in the western church.

ANNATTO. See **ANNOTTO**.

ANNE, queen of Great Britain and Ireland, the last member of the house of Stuart who sat upon the English throne, born at Twickenham, near London, Feb. 6, 1664, died Aug. 1, 1714. She was the second daughter of James II., then duke of York, by his first marriage with Anne Hyde, daughter of the illustrious Clarendon. Though both her parents became attached to the Roman Catholic church, she was educated in the principles of the church of England, and in 1683 was married to Prince George, brother of Christian V., king of Denmark. It was for some time a matter of doubt and deep anxiety what part she would take in the contest which distracted England between James II. and the party of the prince of Orange; but the influence of the vehement duchess of Marlborough, for whom Anne had a romantic fondness, at length made her decide the question against the promptings of filial affection. She renounced the purpose of accompanying her father in his exile, adhered to the dominant party, and by the act of settlement the British crown was guaranteed to her and her children in default of issue to William and Mary. She lived in retirement till the death of William, and the friendship between her and the king and queen was only formal. Of the 17 children whom she bore to her husband, only one survived infancy, the duke of Gloucester, who died in 1700, at the age of 11. On the death of William in 1702, Mary having previously died without heirs, Anne ascended the throne. Though feeble in character, she pursued the plans of her predecessor against the ambition of Louis XIV., and on the day of her coronation the triple alliance was renewed between England, Holland, and the German empire, against France. This was shortly after the opening of the war of the Spanish succession, in which Prince Eugene and Marlborough, by the victories of Oudenarde, Ramillies, and Blenheim, drove the French troops from the Danube across the Rhine. In the battle of Malplaquet, the son of James II., the chevalier St. George, charged at the head of the French cavalry the army of

his sister Anne, commanded by Marlborough. The most important conquest made by England in this war was the fortress of Gibraltar. The great political event of the reign of Anne was the union of England and Scotland, completed May 1, 1707. In 1710 the popularity of Marlborough, who had been for eight years the idol of the queen, the parliament, and the people, began to wane, and his duchess lost the queen's confidence. The Tories, who now had in their ranks the ablest statesmen and the most effective writers, increased in power, and the whigs completed their own ruin by the prosecution of Dr. Sacheverell for preaching in favor of the divine right of kings. In the new election the Tories were successful, a new ministry was formed, in which Harley, afterward earl of Oxford, and Lord Bolingbroke were the chiefs, and a new favorite, Mrs. Masham, the daughter of a London merchant, reigned at court. It was determined to conclude peace, and the fruits of the war, not less than the allies of England, were neglected in the treaty of Utrecht, signed April 11, 1713. The new leaders were not harmonious, and though the crown had been settled, in the event of Anne's death without children, upon the princess Sophia of Hanover, the granddaughter of James I., yet the court and courtiers were occupied with intrigues to give the succession to the son of James II., James, the chevalier St. George. The queen, wearied with the wrangling and cabals of her ministers, suddenly died; and her death, at a moment when the plans of Bolingbroke were immature, was perhaps the means of securing peacefully to England the Protestant succession. Anne was deficient in mental vigor, but amiable. Though she was obliged twice to set a price upon the head of her brother, she seems to have cherished for him a strong affection. Her reign, distinguished by successful wars, has also been called the Augustan period of English literature. The writings of Addison, Pope, Steele, Swift, and Defoe adorned the age, and periodical sheets and newspapers, such as the successive numbers of the "Spectator," then first came into fashion.

ANNEALING (Sax. *anaban*, to heat), a process of softening and toughening certain metals and glass by heating them, and then cooling them very slowly. In working some of the metals under the hammer, or in rolling them into plates, or in drawing them out into wire, they become hard and brittle, so that the process cannot be continued without restoring them to their former condition. This is done by annealing. It has sometimes to be often repeated in drawing out a single plate of brass or aluminum. The jarring motion to which the wheels of railway cars and their axles are subjected changes in time the soft, fibrous texture of the iron into a crystalline structure approaching that of cast iron. They become brittle, and can be restored only by working them over and annealing. Intense cold produces a similar

effect when the change of temperature is very sudden. The tempering of steel is an artificial hardening of the same nature. Cast iron may be chilled and become as hard as steel, but brittle. It may be annealed (with a slight change in the composition at the same time) and form malleable castings—even cast-iron nails that will elench.—The subject is more particularly interesting as it relates to the changes effected by temperature in glass. When this is melted and shaped into articles which are allowed to cool in the air, the glass becomes too brittle for any use. The exterior cools first and forms a contracted crust, which shelters the interior particles; so that these continue longer in a semi-fluid state, and are prevented from expanding, as glass does in cooling, and uniting with the rest to form a homogeneous mass. The inner parts are thus constantly tending to expand. If, on the contrary, the glass is placed in a hot oven, and this is allowed to cool very slowly, the particles of glass appear to assume a condition of perfect equilibrium of cohesive force without tension, so that the mass becomes tough and elastic. The extreme effect of sudden cooling is very curiously shown in the philosophical toys called Prince Rupert's drops and the Bologna phial. The former, which were shown by Prince Rupert to Charles II. in 1661, are little pear-shaped lumps of glass, with a curved stem, formed by dropping melted glass into water. Most of the particles burst to pieces, but some assume this form. When taken out of the water they will bear a smart blow without breaking, the effect being spread equally throughout the whole body; but if a little piece be broken off the end of the stem, they will fly into fragments with a sort of explosion. Dr. Ure explains this phenomenon by referring it to the tendency of a crack once formed in the glass to extend its ramifications in different directions throughout the whole mass. The same effect is observed in the very large sheets of plate glass used for shop windows: once cracked, they are seen in time to fall to pieces, the cause no doubt being imperfect annealing. The Bologna phials are made of unannealed glass, 3 or 4 inches long and about $\frac{1}{4}$ of an inch thick. No regard is paid to their shape. They will bear a pretty hard blow with a hammer handle on the outside, or a small bullet may be dropped into one without breaking it; but if a sharp fragment of sand, or small piece of stone, be dropped in, the glass will burst in pieces, generally at once, but sometimes after a considerable interval.

ANNE ARUNDEL, a central county of Maryland, on the W. shore of Chesapeake bay, bounded N. by the Patuxent river, W. by the Patuxent, and watered in the eastern half by the South and Severn rivers; area, 750 sq. m.; pop. in 1870, 24,457, of whom 11,732 were colored. The surface is undulating and hilly, and the soil is fertile. In 1870 the county produced 126,451 bushels of wheat, 560,359 of corn, 65,888 of oats, 3,020,455 lbs. of tobacco,

21,521 of wool, and 142,632 of butter. Copper and iron ore are found. The Annapolis and Elk Ridge railroad passes through the county. Capital, Annapolis.

ANNE OF AUSTRIA, queen of France, daughter of Philip III. king of Spain, born Sept. 22, 1601, died Jan. 20, 1666. She was married in 1615 to Louis XIII., and in 1638, 23 years after her marriage, became the mother of Louis XIV., and in 1640 of Philip of Orleans, the first of that branch of the house of Bourbon. Cardinal Richelieu, the all-powerful minister of the weak Louis XIII., dreading the influence of the queen, or, as others pretend, having been refused by her as a lover, succeeded in prejudicing the mind of the king till he allowed Anne to be continually persecuted, exiled, and at times left to suffer the greatest penury. Richelieu accused her of conspiring with the dukes of Lorraine, with England, with her brother the king of Spain, with all the enemies of France, and with the conspirators at the court, against his own supremacy. At the death of Louis XIII. in 1643, the parliament, contrary to his will, appointed her regent during the minority of Louis XIV. Cardinal Mazarin, who is supposed to have been secretly married to her, ruled in her name, and provoked the revolt of some of the princes of the blood and other French grandees known as the war of the Fronde (1648-53). (See *FRONDE*.)

ANNE BOLEYN, Bullen, or *Boulayne*, queen of England, one of the wives of Henry VIII., beheaded May 19, 1536. The date of her birth is uncertain, some authorities placing it as early as 1500, others as late as 1507. She was a daughter of Sir Thomas Boleyn, afterward created Viscount Rochford and earl of Ormond and Wiltshire, and was one of the ladies selected to accompany the princess Mary to France at the time of her marriage with Louis XII. in 1514. When Mary returned after Louis's death, Anne remained behind attached to the household of Claude, the queen of Francis I. She was recalled to England in 1522 (or according to Froude in 1527), and admitted to the household of Catharine of Aragon. Here she seems to have been circumspect in her behavior, witty, vivacious, and accomplished. The stories of her questionable conduct at the French court rest upon insufficient testimony. It was not long before she attracted the attention of Henry, who obliged Wolsey to interfere and break off a proposed marriage between Anne and Lord Percy, son of the earl of Northumberland. Anne grew in favor precisely as the royal scruples about the validity of the marriage with Catharine increased. It was in the latter part of 1527 that Henry openly declared to Wolsey his intention to marry Anne as soon as the divorce could be obtained. The cardinal's opposition soon gave way before Henry's violent will, but Anne always looked upon Wolsey as her rival, and could not rest until she had persuaded the king to disgrace him. At last, after five years' agitation of the divorce, Anne was married to the

king at Whitehall, Jan. 25, 1533, by Dr. Lee, one of the royal chaplains. She had already for three years resided in the palace and been Henry's constant companion, and a few months before the wedding had been created marchioness of Pembroke. The divorce question was now brought into the ecclesiastical court of Canterbury, where Cranmer had been created archbishop on purpose to decide it. In May he pronounced the marriage with Catharine null from the beginning, and Anne the lawful wife of his majesty; and on June 1 her coronation was performed with great pomp. Three months later was born the princess Elizabeth, whose subsequent reign shed so much splendor upon English history. The life of the court while Anne shared the throne was gay and easy; and when Henry began to tire of her and find stronger attractions in Jane Seymour, it was not difficult to convict Anne of improprieties, to say no worse. A committee, including with other lords her own father, appointed to inquire into her conduct (April, 1536), reported her incontinent with Brereton, Norris, and Weston of the privy chamber, Smeaton, the king's musician, and even her own brother, Lord Rochford. All the accused were sent at once to the tower. Anne was tried by a commission of peers under the presidency of her uncle, the duke of Norfolk, and found guilty, partly on the confession of Smeaton, though she herself and the other prisoners protested innocence to the last. Cranmer was compelled to pronounce her marriage with Henry null and void, as he had formerly pronounced Catharine's. Her prison hours were spent in alternations of composure and excitement; but on the scaffold she conducted herself with queenly dignity. Smeaton was hanged, and the other four accused were beheaded.

ANNE OF BRITTANY, queen of France, born in Nantes, June 26, 1476, died in the castle of Blois, Jan. 9, 1514. She was the daughter and heiress of Francis II., duke of Brittany. That duchy was her dowry on the marriage with Charles VIII., son of Louis XI. of France, Dec. 6, 1491, and thus became incorporated with France. She was previously affianced to Maximilian of Austria, but her guardian, Louis XI., dissolved the engagement, and thus assured the aggrandizement of his kingdom and family. After the death of Charles VIII., in 1498, she married his successor, Louis XII., and exercised a great influence over her husband and all around her. She was an example of virtue and industry, and administered the kingdom with ability during the campaigns of her husbands in Italy.

ANNE OF CLEVELAND, daughter of Duke John III., and fourth wife of Henry VIII. of England, died at Chelsea, July 16, 1557. To please the Protestant party, and to make friends among the Protestant German princes, Henry wedded her with reluctance, Jan. 6, 1540, but divorced her in July of the same year, and settled upon her an annuity of £3,000.

ANNECY, an old town of Savoy, capital of the French department of Haute-Savoie, pleasantly situated near the lake of its name, 22 m. S. of Geneva; pop. in 1866, 11,551. It has various factories, cotton-spinning mills, glass and iron works, and is the seat of a bishop. St. Francis de Sales was born here, and his relics are preserved in St. Mary's church.

ANNELEIDA (Lat. *annellus*, a small ring), red-blooded worms, such as the earth worm, the lug worm, and the leech. They are the only section of invertebrate animals which have red blood. They form an extensive class, subdivided into four orders by Milne-Edwards. The body has an elongated form, with distinct, soft, semi-cartilaginous annulations, connected together by longitudinal oblique muscles, enabling the animals to twist themselves in various directions. The whole is covered with a moist skin, indicating by slight segments the soft annuli beneath. The first segment is furnished with a mouth, and in some species with eyes and tentacles; the last segment is furnished in some cases with bristle-like appendages, and in others, as in the leech, it is dilated into a sucker. Each segment has usually minute setæ, or spines, which are useful in locomotion. In some species vascular tufts are observed, which serve as respiratory organs. There is a system of veins and arteries. The nervous system consists of ganglia, united by means of a double nervous cord. Each individual is bisexual. The common or earth worms seek safety by retiring into holes which they bore in soft earth, mud, or sand. The *sabella* and *terebella* of the seashore agglutinate around them particles of sand and of broken shells to form a case in which they dwell. The *serpula* exudes a calcareous secretion to form a long twisted tube, in which the animal resides, and from which it protrudes its head and respiratory tufts. The four orders of this class are: 1, the *dorsibranchiatus*, or *errantes*, including the sea centipedes and sea mice; 2, the *tubicola*, which include those that live in tubes, as the *serpula*; 3, the *terricola*, including the common earth worm; and 4, the *suctoria*, having suckorial disks, as the leech. From the recent researches of Prof. Edward S. Morse, it appears that the *brachtopoda* come near the tubiculous annelids; and he therefore removes them from the mollusca to the annelid division of articulatæ.

ANNESLEY, Arthur, first earl of Anglesey, born in Dublin in 1614, died April 6, 1686. He was the eldest son of Sir Francis Annesley, afterward Baron Mountnorris and Viscount of Valentia. He was among the loyal members who met in the parliament summoned by Charles I. at Oxford in 1643. The royal cause having become almost hopeless, he joined the parliamentarians, and was one of the three commissioners appointed to settle the affairs of Ireland in 1645. He took an active part in the restoration of Charles II., and in 1661 was created Baron Annesley and earl of Anglesey

in the peerage of England. He was afterward made treasurer of the navy and lord privy seal, and held the latter office till 1682, when he was dismissed for favoring the exclusion of the duke of York from the throne. He published several works on polenics, politics, constitutional law, and parliamentary privileges.—**JAMES ANNESLEY**, Lord Altham, his grandson, born in 1715, was kidnapped by his uncle and sent to America, where he was 13 years in slavery, but finally in 1743 established his legal right to the honors and estates of the earls of Anglesey, though he never assumed the title. Smollett gave the leading facts of the case in his novel of "Peregrine Pickle."—The earldom of Anglesey expired in 1761, but the Irish peerages of Annesley and Valentia are held by descendants of Arthur Annesley.

ANNUS OF VITERBO, an Italian Dominican, born at Viterbo about 1432, died Nov. 13, 1502. His real name was Giovanni Nanni, which he Latinized into Johannes Annius. He enjoyed the especial favor of Pope Alexander VI. and his family; though his death was believed to have been caused by poison administered by command of Cæsar Borgia, who wished to be rid of one whose plainness of speech offended his pride. Annius published in 1498 *Antiquitatum Volumina XVII.*, purporting to be a collection of works of ancient authors previously supposed to be lost, including Berosus, Marcus Cato, Manetho, and others. It has long since been condemned as spurious.

ANNO, or **Hanno**, **Saint**, archbishop of Cologne, died Dec. 4, 1075. He belonged to a noble family, and was destined at first to the profession of arms. He was chancellor under the emperor Henry III., and tutor of Henry IV. After the death of Henry III., aided by Archbishop Adalbert of Bremen, and others, he obtained the regency, but soon laid it down in disgust. The hymn of St. Anno, composed about a century after the archbishop's death, is a kind of panegyric on the saint, commencing with the popular traditions of Germany, and touching on the history of the archiepiscopal see of Cologne, and of 33 bishops before the poet, among whom were seven saints. It was first printed from a forgotten manuscript by Martin Opitz of Dantzic in 1639.

ANNONAY, a town of southern France, department of Ardèche, 37 m. S. of Lyons, noted as the birthplace of the Montgolfiers, inventors of the air balloon, and for its paper made at mills erected by these famous brothers; pop. in 1866, 18,445. It has several celebrated manufactories of gloves. It is the point of junction of the Cance with the Déaume river, which is here crossed by a suspension bridge.

ANNOTTO, **Annatto**, or **Arnatto**, a red coloring matter extracted from the outer part of the seeds of a Brazilian evergreen, called the *bixa Orellana*. Dissolved in an alkali, as a crude pearl-ash, its color changes to orange. It is used to color milk, butter, and cheese. Dyers, painters, and soap-makers also make use of it.

Though employed only for disguising other substances, it is itself probably more adulterated than almost any other article of commerce. It has been purchased containing over 60 per cent. of chalk, and is often found contaminated with red lead, so that cheese colored with it has been made poisonous. Other substances usually mixed with it are turmeric, rye, barley, and wheat flour, sulphate of lime, salt, alkali, Venetian red, and copper.

ANNUITY, a yearly payment, subject to various conditions. The payment may be stipulated without regard to any contingency, in which case it is called an annuity certain. If limited in time, it is called a term or temporary annuity certain. If no limit is fixed, it is called a perpetuity. A contingent annuity is one of which the payment is limited by the occurrence of some future event, uncertain as to time, but more or less probable. It is temporary when it must cease at a fixed time, provided it has not already ceased by the previous occurrence of the contingent event. The consideration for insurance, as generally paid, is an example of contingent annuity, but is called premium. Annuities paid as reward for meritorious services are called pensions; and those paid for the use of real estate are called rent.—Though the term annuity implies a year as the interval between the payments, yet in practice it is made to include any series of equal or uniformly increasing or decreasing payments at equal intervals, as annual, semi-annual, quarterly, or monthly; and in mathematical theory the intervals may be infinitely small, when the annuity is said to be payable momentarily.—The most important contingency ever introduced into annuity contracts is that of death. A fixed sum which is payable at equal intervals during the entire life of a person is called a life annuity. If it depends on two or more lives, and is to cease on the death of either, it is called a joint life annuity. A survivorship annuity is one which so depends upon two or more lives, that it is to commence only when one or more begin to be survivors. These annuities may be temporary, or for the whole life, immediate or deferred; that is, the first payment may take place in advance or immediately after the occurrence of the contingency, or it may be deferred one or more of the equal intervals. The most important question in regard to any such series of payments is its present value. This would be easy to answer in regard to annuities certain, but for the interest of money. For if money earned no interest, the present value would be the sum of all the future payments, which in case of a perpetuity would be infinite. If we assume any perpetual rate of interest, the present value of a perpetuity at that rate is obviously the principal that will yield that interest; and this principal is always less in regard to a given interest as the rate is higher. Any term annuity certain may be considered as the early portion of a perpetuity. Hence the difference between the principal, P, which

is the present value of the perpetuity, and the same discounted at compound interest for the intervals of the term n , at the assumed rate i ($P - \frac{1}{(1+i)^n} P$), is the present value of the term annuity for n intervals. The subtractive quantity ($\frac{1}{(1+i)^n} P$, or $v^n P$ as it is usually written) is called the reversionary value of the term annuity, or of the estate whose income is absorbed by its payment. Any annuity is said to be worth as many "years' purchase" as the times it is contained in its present value.—The present value of any life annuity involves a medical as well as a mathematical question. The mathematical solution, which comes first, is founded on an assumed rate of mortality, more or less worthy of confidence, according to its agreement with observed facts when taken in large numbers. This gives the value supposing the life in question possessed of the average vitality due to its age. Medical science will modify this result so far as it can determine a variation of the individual from the assumed average, though it has no means of fixing a definite or numerical variation. It is a common mistake to suppose that the present value of a life annuity can be found from the "expectation of life," or average after-lifetime at the given age, by finding the present value of an annuity certain for the term of that expectation. This can be true only when the assumed interest is zero. This popular error has been much fostered by life insurance companies publishing tables of "expectation," which can have no possible application to their business except by this erroneous method, and which, so applied, only prove their premiums too high. The only correct method of applying the rates of mortality and interest to ascertain the present value of any series of payments contingent on life, is to apply them separately to each and every possible payment. Each future payment must, in effect, be multiplied by the present value at compound interest of a dollar, or monetary unit, payable certain at that time; and this product must again be multiplied by the fraction, derived from the table of mortality, expressing the probability of the party being then alive to pay it. The sum of as many such products as there are possible payments is the present value of the life annuity. When only one or two lives are concerned, there are tables which abridge the operation to a narrow compass; but when there are three or more, the combinations become too numerous to admit of exhaustive tables, and mathematicians content themselves with methods of approximation to solve particular problems.—After the mathematical solution, which can only be as correct as the assumptions on which it is founded, comes the medical, weighing the special facts by which the individual case differs from the average or general type. The reason why the business of selling annuities to commence in a year or less is always unprofitable to an honest company,

and why it is unprofitable to a government as a means of borrowing money, is that the medical selection is in favor of the buyer. On the contrary, companies dealing in policies of insurance, or selling annuities long deferred, succeed by a medical selection in their own favor.—The most valuable recent contributions to the basis for calculating life annuities are contained in the works of Chisholm, and the writings of Dr. Farr, in connection with the reports of the registrar general of Great Britain. Very valuable observations have also been made by Mr. Meech on the United States census of 1860, and by Mr. Elliott on the population returns of Massachusetts.

ANNUNCIATION, the announcement to Mary by the angel (Luke i. 30-33) that she should conceive and bear the child Jesus. In commemoration of this event, the church instituted the feast of the Annunciation, to be observed on the 25th of March. In old style this day commenced the year. Writers differ as to the time when this feast was instituted. Some throw it as far back as the 4th century, since there is mention of it in a sermon ascribed to Athanasius. Others think its origin is to be assigned to the 7th century, which is the most probable opinion, as the sermon of Athanasius is believed to be spurious.

ANODYNE (Gr. *an* privative and *odōnē*, pain), a term properly applied, not to medicines which relieve pain by removing its cause, but to those which merely diminish the conducting power of the nerves of sensation, or which render the brain less susceptible to or less conscious of pain. The principal medicines of this kind are opium, belladonna, and hyoscyamus, with their alkaloids, Indian hemp, ether, and chloroform. The last two are usually called anæsthetics, because they diminish the power of the brain to receive impressions from any external source. The use of anodynes is generally to be looked upon as the substitution of a lesser evil for a greater, and a habitual resort to them is always, if possible, to be avoided.

ANOINTING, an ancient custom of pouring aromatic oils on persons as a token of honor. It was employed in consecrating priests, prophets, kings, and the places and instruments appointed for worship. In the Old Testament, the anointed of the Lord is a person upon whom God has conferred a particular dignity, and whom he has appointed to a special ministry. The anointing oil was often a very costly preparation. Olive oil, spikenard, and myrrh were the more common materials. A very precious oil, the holy oil, was used in the service of the sanctuary, and could not be applied to any ordinary purposes. The Roman Catholic church has retained anointing as a symbol in its sacraments of baptism, confirmation, ordination, and extreme unction. In consecrating a church, the bishop anoints the walls of the edifice and the altars which are to serve in the celebration of the mass. Anointing with perfumed oil was in common use among the

Greeks and Romans as a mark of hospitality to guests, and modern travellers in the East still find it a custom for visitors to be sprinkled with rose water, or to have their head, face, and beard anointed with olive oil.

ANOKA, an E. county of Minnesota, bounded S. W. by the Mississippi river, and intersected by Rum river, one of its branches; area, 420 sq. m.; pop. in 1870, 3,940. The productions in 1870 were 27,390 bushels of wheat, 17,715 of oats, 36,838 of corn, 15,872 of potatoes, and 5,246 lbs. of wool, and 11,200,000 feet of lumber was sawed. Capital, Anoka, at the mouth of Rum river, 22 m. N. N. W. of St. Paul.

ANOLIS (*anolis*), a reptile of the saurian family, peculiar to America, belonging to that section of the iguanas which Cuvier distinguishes as having teeth on the palate of the mouth as well as on the interior jaw bones. Its body, legs, and tail are long and tapering. The fore legs are longest, having five toes furnished with sharp, hooked claws, with a sort of pad ap-

Crested Anolis
(*Anolis velifer*).
Green Carolina Anolis
(*Anolis principalis*).
Red-throated Anolis
(*Anolis bullaris*).

pended to the under side of the last joint, which increases the power of their hold on any substance over which they may chance to be walking. There is a large extent of loose skin extending from the chin to the belly, which when not distended forms a longitudinal fold under the whole lower surface of the animal. The anolis has a singular serrated or saw-edged crest along the spine and upper side of the tail, and the whole animal is covered with small, round scales, which give it a granulated appearance resembling the finest shagreen. The anolis seems in many respects to supply in the new world the place occupied by the chameleon in the old. Its colors change with the same or even greater rapidity, especially on the loose skin of the throat, which is constantly distended when the animal is actuated by strong passions, and in this state it assumes an endless

succession of ever-varying hues. It frequents woods, coppices, and rocky places; climbs and leaps so swiftly and rapidly that its movements can hardly be traced; and, when overheated or fatigued, pants like a tired dog. It is a gentle, inoffensive creature, feeding on insects and flies, and is easily alarmed. There are six species, two of which belong to the United States, and the others to the Antilles and to South America. 1. *A. velifer* is of a beautiful ashy blue color, and is the largest of the family. Its body is about a foot long, and the tail a foot and a half. The crest extends along the top of the tail for half its length from the origin, and is supported by from 12 to 15 rays. It is a native of the West Indies. 2. *A. bimaculatus* is little more than half the size of the former species, is of a greenish blue color, clear on the head and upper parts, but variegated with brown on the body, tail, and extremities. It is found from Pennsylvania to the shores of the gulf of Mexico and in the Antilles. 3. *A. equestris* has scarcely any crest, and is nearly the size of *A. velifer*. 4. *A. bullaris* is not above half the size of *A. equestris*, with a reddish green throat, and very pretty. It is green in color, has a short muzzle spotted with brown, and, except in the absence of the crest or tail, is very similar to *A. bimaculatus*. It belongs to the Antilles. 5. *A. lineatus* is of a pure, bright green color, rather larger than the last species, and is marked along each flank with two parallel lines of oblong black spots; it is a native of different parts of South America. 6. *A. principalis* is a native of South Carolina, and is known as the green lizard. It is a beautiful greenish gold-colored reptile, particularly distinguished by a black band on the temples, and the elongated and flattened form of its muzzle.

ANQUETIL, Louis Pierre, a French historian, brother of Anquetil-Duperron, born in Paris, Feb. 21, 1723, died Sept. 6, 1808. He was an ecclesiastic, and published a history of Rheims (1756), a history of France (14 vols. 12mo, 1805), historical monographs on the times of Henry IV., Louis XIII., and Louis XIV., and a *Précis de l'histoire universelle* (9 vols. 12mo, 1797; 12 vols., 1801 and 1807), part of which was composed in prison during the reign of terror. His *Motifs des guerres et des traités de paix de la France* (1798) is praised for its evidences of profound knowledge of diplomacy and its sound judgment.

ANQUETIL-DUPERRON, Abraham Hyacinthe, a French oriental scholar, born in Paris, Dec. 7, 1731, died there, Jan. 17, 1805. He was educated for the church, but preferred to devote himself to oriental literature. In his enthusiasm for this pursuit he enrolled himself as a common soldier in the expedition to the French colonies in the East Indies, in 1755, chiefly for the purpose of discovering the ancient books of the Parsees. He visited Chandernagore, Surat, the coast of Coromandel, and was just about proceeding to Benares when the capture

of Pondicherry forced him to return to France, where he arrived in 1762, without money, but with valuable oriental manuscripts. He was appointed interpreter of oriental languages at the royal library, was admitted to the academy of inscriptions and belles-letters, and in 1771 he published in French the first translation of the *Zend-Avesta* ever made in an occidental language, with an account of his travels and a life of Zoroaster.

ANSALONI, Giordano, a Sicilian Dominican missionary, died by torture at Nagasaki, Japan, Nov. 18, 1634. Hearing that in the Japanese islands Christians were persecuted with the utmost barbarity, he went with a Spanish missionary expedition to the Philippine islands, learned the Japanese language in a Chinese and Japanese hospital at Manila, and in 1632 went to Japan, where he spent two years in the disguise of a native priest. He was finally discovered and arrested at Nagasaki, where he was tortured to death. Another priest and 69 converts were put to death at the same time.

ANSARIES, or **Ansarians** (Arab. *Anseriyeh*), also called **Nossairians**, an Arab tribe or sect inhabiting the mountainous district between the northern part of the Lebanon and Antioch, Syria. This range, called the Ansarian mountains, is much lower than the Lebanon, not averaging more than 4,000 feet. Limestone is the prevailing rock, and thin oak forests cover almost the whole ridge. The Ansaries are to be found also in Antioch, Saida, Latakieh, and other towns and villages on the coast. Their chiefs live in Bahluh, Simrin, and Safeta. Of their origin and early history little is known. They endeavor to conceal their doctrines from all foreigners, and only male adults are initiated. Among Moslems they, like the Druses, profess Mohammedanism. Their prophet Nossair taught that God has appeared 11 times in human form, in Abraham, Moses, Jesus, Mohammed, Ali, Hakem-bi-amr-Allah, and other imams; that he always encountered opposition and then returned to heaven, where he wrapped himself in a blue mantle, and at length retired to the sun, which is therefore worshipped by the Ansaries. They wait for the appearance of a Mahdi or Messiah, who will be the last of the 12 imams in whom the Deity assumes a human form. Like the Yezidis of northern Syria, they allow promiscuous intercourse of the sexes on certain festivals, and in performing their religious rites they are said to be very licentious. They believe in the migration of souls, which for the faithful is a progressive purification till they become stars; but those who neglect their religious duties, betray the mysteries, or deny the divinity of Ali, are doomed to transformations into Jews, Christians, Mohammedans, donkeys, dogs, and hogs. They have four degrees: *shamsi*, worshippers of the sun; *kamari*, worshippers of the moon; *klesi* or *kadami*, worshippers of women; and *shemali* (*shemal*, north; literally, northerners). They practise

circumcision and ablutions, and pray three times a day under the open sky. Their chief religious festival is called the *Chadir*. Their doctrines teach them benevolence, honesty, and patience in adversity, but they are thievish, superstitious, and ignorant, though very hospitable. Each community is governed by a *mokaddem*, who is almost wholly independent. They have frequently defended their freedom with great courage against Turkish and Egyptian pashas. During the crusades they were found in all parts of Syria and Mesopotamia. The accounts given of this sect by modern travellers vary, and must be received with caution. According to Mme. Audouard (*L'Orient et ses peuplades*, Paris, 1867), they are divided into three parties, considerably differing from each other. The most numerous of them worship a beautiful young woman, who is elected to the dignity of goddess every third year.—Among the Ansaries it is usual to reckon the sect of the Kadamissh, who live east of them in several valleys of the Cadmus mountains. They keep apart, however, from the Ansaries, do not intermarry either with them or any other neighboring sect, and have their own religious customs. Like the Assassins of the middle ages, they call themselves Ismaelians.

ANSARIUS, or **Ansgar** (Fr. *Anchaire*). **Saint**, the "apostle of the north," born in Picardy in 801, died at Bremen in 864. Educated in the old Benedictine monastery of Corbie, near Amiens, he was early transferred to a new one recently founded at Korvey on the Weser, where he distinguished himself as a teacher. When Harold of Denmark, who had been baptized in Mentz, returned to his country, he took with him as missionaries Anscarius and his colleague Audibert. Success at first attended their efforts, but after a time they, as well as the king, were expelled from the country. Anscarius in 829 penetrated into Sweden, where he obtained from the king, Biörn, permission to preach, and made many converts, returning to his monastery in 831. In the same year Pope Gregory IV. made him archbishop of Hamburg and apostolic legate, and to this appointment the bishopric of Bremen was afterward added. Pope Nicholas I. appointed him his legate to preach the gospel among the Swedes, Danes, and Slavs. He won the favor of King Eric of Jutland, and succeeded in preaching the Christian religion there in 862. In Sweden he reformed many disorders which had grown up among the new Christians. Anscarius was not indeed the first who attempted to propagate the gospel in northern Europe, but he was the first to firmly plant Christianity among the Danes and Swedes.

ANSDELL, Richard, an English painter, born in Liverpool in 1815. He is known chiefly as a painter of animals and field sports, although occasionally attempting a historical work, such as "The Battle of the Standard." Among his best pictures are a number on Spanish subjects. He has also worked in conjunction with Creswick, the landscape painter.

ANSELM, a saint and doctor of the Latin church, born at Aosta in Piedmont about 1033, died in Canterbury, England, April 21, 1109. His youth was dissolute, until, at the age of 27, he entered the Benedictine monastery of Bec in Normandy, of which in 1063 he succeeded Lanfranc as prior, and in 1078 became abbot. In 1092 he was invited to England, and in 1093 was consecrated archbishop of Canterbury as successor to his friend and master Lanfranc, since whose death in 1089 the see had been vacant. In this office he had several memorable conflicts with William Rufus and Henry I., especially on the subject of ecclesiastical investitures, and was deprived for a time of his bishopric, passing several years in France and Italy. Anselm is generally regarded as the earliest of the scholastic theologians. As a religious philosopher he had no superior in his own age, and few superiors in any age. His greatest works, and those which have won for him the surname of "the Augustine of the middle ages," are his treatise *De Concordia Prædestinationis*, and the treatise *Cur Deus Homo*, in which he illustrates the doctrine of satisfaction, which has since his time ruled in the theory of the atonement. The best and most complete edition of the works of Anselm is that issued in 1675 at Paris, under the direction of the Benedictine monk Gabriel Gerberon.

ANSON, a S. county of North Carolina, bordering on South Carolina, bounded N. by Rocky river, and E. by the Yadkin; area, 650 sq. m.; pop. in 1870, 12,428, of whom 6,951 were colored. The Yadkin furnishes abundant water power. The surface is hilly; the soil is good and well suited to cotton. The productions in 1870 were 39,928 bushels of wheat, 149,726 of corn, 46,851 of oats, 25,569 of sweet potatoes, and 4,311 bales of cotton. There are several cotton factories. The county was named in honor of Lord Anson, who owned a great deal of property here. Capital, Wadesboro.

ANSON, George, lord, an English admiral and navigator, born at Shugborough, Staffordshire, April 23, 1697, died June 6, 1762. He entered the navy when a boy, was made a post captain in 1724, and received the command of the Scarborough man-of-war. Between 1724 and 1735 most of his time was spent on the Carolina station, where he founded the town of Ansonburg. In 1739 England declared war with Spain, and he was appointed to the command of a squadron which was to proceed to the South sea, and harass the Spanish trade and settlements in that quarter. The expedition, wretchedly equipped, heavily laden with private merchandise in spite of Anson's remonstrances, and some of the vessels unseaworthy, sailed Sept. 18, 1740. He lost part of his fleet off Cape Horn, a great part of his men died of scurvy, and he finally crossed the Pacific ocean with only a single ship. In consequence of these disasters, the original object of the expedition was abandoned, but Anson was enabled to explore the coasts and islands of the

Pacific, and make important discoveries. Every coast and harbor he visited was carefully surveyed, and he made a large collection of Spanish charts and journals. With his single vessel he took Payta, on the coast of Peru, and a number of ships, among them the Manila galleon, laden with treasure. Throughout the voyage he showed great courage, prudence, and fertility of resource, besides tender care of his sick men and humanity toward his prisoners. He returned home with his prizes in June, 1744, having eluded the French channel fleet during a fog, and was soon afterward made rear admiral of the white and a commissioner of the admiralty, in 1746 vice admiral of the blue, and in 1747 of the red. He commanded the channel fleet in 1746-'7, and on May 3, 1747, captured off Cape Finisterre most of the French India fleet, consisting of nine ships, and carrying over 3,000 men and 420 guns. This achievement procured him a peerage as Lord Anson, baron of Soberton. He was first lord of the admiralty from 1751 to 1756, and again from 1757 till his death. In 1761 he was made admiral of the fleet, and soon afterward sailed from Harwich in the Charlotte yacht, to bring the future bride of George III. to England. Anson's "Voyage round the World," prepared by Benjamin Robins from materials furnished by the navigator (4to, London, 1748), passed through four editions the first year, and has been translated into many languages. His title expired with him, but his name was assumed by his nephew and heir George Adams, whose son was created Viscount Anson, and his grandson earl of Lichfield.

ANSON, George, British commander-in-chief in India, born in London, Oct. 13, 1797, died of cholera at Kurnaul, May 27, 1857. He was the second son of the first Viscount Anson, and uncle of the first earl of Lichfield. At an early age he entered the Scots fusilier guards, with which regiment he served at the battle of Waterloo. In 1825 he was placed on half pay with the rank of lieutenant colonel; in 1831 he became major general. He sat in parliament for many years as a whig. In 1855 he was appointed commander-in-chief in India, where he held the local rank of general. He died soon after the sepoy rebellion began.

ANSONIA, a manufacturing village in the town of Derby, New Haven co., Conn., on the E. bank of the Naugatuck river and on the Naugatuck railroad, 9 m. W. N. W. of New Haven; pop. in 1870, 2,749. It was established by Phelps, Dodge and company of New York, and named from Mr. Anson G. Phelps. It has 11 rolling mills, 2 founderies, white lead works, woollen mills, extensive clock, hoop skirt, and other factories, good public water works, a bank, several churches, and many fine residences. The fall in the river at this point affords excellent water power.

ANSPACH (Ger. *Ansbach*, formerly *Onolzbach*; Lat. *Onoldum*), a town of Bavaria, capital of the government of Middle Franconia,

and formerly of the principality of Anspach-Baireuth, which gave the title of margrave to a branch of the house of Brandenburg. The town is situated at the junction of the Holzbaeh with the Lower Rezat, in the government of Middle Franconia, 24 m. W. S. W. of Nuremberg; pop. in 1871, 12,635. It has a beautiful castle, a picture gallery, a library, manufactures of surgical instruments, cutlery, cotton, woolen, and silk stuffs, leather, earthenware, white lead, tobacco, cards, parchment, &c., and a trade in wool, flax, and grain. It owes its origin to the monastery of St. Guibert, founded here in the 8th century.—The last margrave, Christian Frederick Charles Alexander, son of the duchess of Baireuth, the sister of Frederick the Great, and nephew of Queen Caroline, the wife of George II., was born in 1736 and died in 1806. He spent most of his life in travel and gallantry, married the celebrated Lady Craven (see next article), and left a name renowned in the scandalous chronicles of the continent. In 1790 he sold his principality to Prussia for about \$300,000.

ANSPACH, Elizabeth, margravine of, youngest daughter of the fourth earl of Berkeley, born in December, 1750, died in Naples in January, 1828. She was married in her 17th year to Mr. Craven, afterward earl of Craven. She then had beauty, fascinating manners, and much talent. After having been married 13 years, during which time she had seven children, she separated from her husband, proceeded on a very extensive tour, visiting Italy, Austria, Greece, Turkey, Poland, and Russia, and was received with *éclat* by several crowned heads. Finally she went to reside at Anspach, where she established a theatre, wrote plays and directed their performance, and became an important personage with the margrave, whose wife was generally confined to her chamber by ill health, and soon after died. Lady Craven continued a visitor at Anspach, and accompanied the margrave on his excursions to other courts and his tours through Italy, England, and Portugal. Lord Craven died in September, 1791, and his widow was soon afterward married at Lisbon to the margrave, in a very ostentatious manner. Returning to England, her three daughters refused to see her, "out of respect to their father," her eldest son neglected her, and her brother, Lord Berkeley, reproached her for marrying again so soon after her late husband's death. Her reply was, that "it was six weeks after Lord Craven's decease that she gave her hand to the margrave, which she should have done six hours after had she known it at the time." Queen Charlotte intimated that she could not be received at court, and refused to grant an audience to the margrave, who had settled in England, purchasing Brandenburg house, in the suburbs of London, subsequently so well known as the residence of Queen Caroline. In 1802 the margravine received a patent from the emperor of Germany, creating her Princess

Berkeley; but the queen of England still declined seeing her. In 1806 the margrave died, aged 70, leaving £150,000 to his widow. After wandering over Europe, she finally settled at Naples. Her latter years, spent in literary retirement, were respectable. She wrote several farces and musical pieces, and was an accomplished composer. She published "Memoirs of the Margravine of Anspach, formerly Lady Craven, written by Herself" (2 vols., London 1825), which is only an apology for her life. Among her other works were two volumes of travels in Europe and the East, in letters to the margrave before their marriage.

ANSTED, David Thomas, an English physicist, born in London in 1814. He was educated at Cambridge, and has been professor of geology at King's college, London, and the college of civil engineers at Putney. During the last 25 years he has been principally engaged on works illustrating the application of geology to engineering and mining. Besides several treatises on geology and related subjects, he has published "Scenery, Science, and Art" (1854), "The Channel Islands" (1862), "Correlation of the Natural History Sciences" (1863), "The Ionian Islands" (1863), and "Physical Geography" (4th ed., 1870). He has also contributed largely to the scientific reviews; and while vice president of the geological society he edited several volumes of their quarterly review. As a consulting engineer he has a high reputation.

ANSTER, John, an Irish poet, born at Charleville, in the county of Cork, about 1798, died in June, 1867. He was educated at Trinity college, Dublin, and published in 1819 a volume of "Poems and Translations from the German." These were favorably reviewed in "Blackwood's Magazine," to which some of them had been originally contributed, and gained for him the friendship and encouragement of Coleridge. By his advice, Anster completed his version of Goethe's "Faust," specimens of which had already appeared in "Blackwood." Mr. Anster was called to the Irish bar in 1824, and was for some time regius professor of civil law in the university of Dublin. He published a second volume of "Poems and Translations" in 1837, and an "Introductory Lecture on the Study of the Civil Law" in 1849.

ANSTEY, Christopher, an English satirical poet, born at Brinkley, Cambridgeshire, Oct. 31, 1724, died at Chippenham in 1805. He is only remembered for his amusing satire called "The New Bath Guide," the profit on the sale of which was declared by Dodsley to be greater than he had ever gained in the same period from any other book. The principal targets for the writer's shafts are physicians and Methodists. Smollett borrowed largely from this poem in "Humphrey Clinker."

ANSTEY, Thomas (Chisholm), an English author, born in London in 1816. He was called to the bar in 1839, removed to Ireland, was member of parliament for Youghal from 1847 to 1852, and from 1854 to 1858 was attorney general

at Hong Kong. He has published several works, the most important of which are "A Guide to the Laws of England affecting Roman Catholics" (1842), and "Guide to the History and Constitution of England."

ANT, an insect belonging to the family *formicidæ* (or *formicariæ*, Latreille), of the sub-order *hymenoptera* or membranous-winged insects. There are numerous genera and several hundred species known and described from various parts of the world. Some species have been famed from remote antiquity for the intelligence displayed in their labors. The habits of others are as yet insufficiently studied, or where ascertained exhibit a lower grade of development. Many species, which are common to the temperate regions of both continents, agree in the following respects: they live in communities consisting of hundreds and even thousands of individuals, of which the fertile females are the largest, the males next in size, and the infertile females (commonly termed nurses or workers, and improperly neuters) the smallest. The last, however, in some species are of at least two different sizes, which are respectively known as the

soldier or major and the minor worker. These differ especially from the fertile females in the lack of development in the ovaries and wings. All of these forms, however, are hatched from eggs, not observably differing, which are not glued singly to one spot, as in the honey-bee, nor lodged irremovably in cells of clay, as in the case of many wasps, but are scattered about in parcels of three or more, loosely attached to each other, so that they can be separated and carried from place to place at pleasure, during the process of hatching. This is during that season the principal duty of the female and of the nurse ants, as it is afterward to do the same by the large cocoons. This transportation of the eggs has, from their resemblance, led to the erroneous idea that ants lay up grain for winter use; whereas many species never feed at all during the winter, remaining torpid. The eggs are exposed by the worker, or by the female when alone, to the rays of the sun during the early morning, covered from its too powerful influence during the extreme heat of the day, and removed beyond the influence of cold or wet by night. As soon as the larvæ or grubs are hatched, they

are treated in the same manner. Until their maturity the grubs, which are necessarily voracious, since they have not only to take up material sufficient for their own growth, but for the formation of the substance whence to spin their cocoons, are fed by the nurse ant, or by the female when alone, with a liquid disgorged from the stomach of the parent. When a female has founded her colony alone, she must be at work early and late, in order to collect sustenance sufficient for herself and for the support of the 20 or more greedy grubs. As soon as the grubs have attained maturity, if of those species which are destitute of stings, they generally spin their cocoons, of a membranous texture and a brownish-white color, which considerably resemble barleycorns. The cocoons are treated precisely as were the eggs and the grubs, in their exposure to proper temperature, and their removal from undue extremes of heat or cold, until they are ripe for their second birth, when the young ants are cut out of their cerements by the mandibles of the nurse ants. Early in the pairing season, both males and females are to be seen in great numbers in all the ant hills, provided with glistening wings, mixed with the wingless workers, who keep diligent watch over them, posting regular sentries and never allowing them to escape beyond the limits of the colony without a guard, several of whom may at times be observed dragging back a deserter by the limbs. There always seems to be a disposition among the winged ants to desert the colony, but the workers never accede to this truant disposition, but resist it to the utmost, nor ever yield unless the breeders become too numerous to be fed or guarded by them. The actual copulation does not take place in the ant hills, but at some small distance from them, and not infrequently in mid-air; and scouts are always on the lookout to drag back the fertilized females to the principal settlement, or to form small independent parties, which seize a female and found a colony on their own account. Sometimes it will happen, so great is this propensity to ramble on the part of the females after their impregnation is complete, that an original settlement is wholly deserted, owing to the workers who have gone off in pursuit, if they have been led too far from home to care about return, forming fresh colonies in whatever place they succeed in capturing a fugitive queen. Occasionally, when an impregnated female escapes by herself, she lays her eggs and establishes her own colony, unassisted by the workers; in which case she herself performs the duties to the eggs which would otherwise be rendered by the nurse ants. The males, after their duties of impregnating the females are performed, are permitted to stray away after their own pleasure, without any effort on the part of the workers to retain them, and die shortly afterward. It was formerly supposed that all ants procured wings at a certain stage of their growth; but

it was discovered by the younger Huber that in the males and females they are gradually developed from the first day of their existence, until, when their purpose has been fulfilled, they are dislocated and cast aside like worn-out clothes. Besides the labors of the working ants, or neuters, already described, they have the task of forming the streets, chambers, and habitations of the colony, repairing them, thatching them, fortifying them against the weather by various operations of mining, masonry, or carpentry, performed with wonderful skill, and under circumstances which prove the possession of some powers or senses beyond our comprehension. It is, however, noticeable that the possession of elbowed or flail-shaped antennæ is almost invariably associated with a high degree of intelligence, evidenced by constructive ability, command of language, &c., as in the bees, wasps, and ants.—The most remarkable of the mining ants are the *formica sanguinaria* of Germany and the *F. cæspitum* or tuft ant of England, which perforate long galleries in the clay, removing all the rubbish, and building buttresses to support their work, by aid of their mandibles only, and then overcasting the whole with a thatch of grass stems and heather against wet or cold. The most common of the mason ants are the red and yellow field ants, which erect superficial habitations; first raising pillars, then springing arches from pillar to pillar, and lastly erecting above them the loose piles of soil which we know as ant hills. Their materials for these edifices are the soil, sand, and clay, kneaded with rain water into a tenacious mortar, which is besmeared over wheat stalks, blades of grass, or any casual supports which they can find. The carpentering ants are those which, like the emmet, *F. fuliginosa*, of Europe, and the *F. caryæ* or walnut ant of the United States, perforate their cells in the solid timber of growing trees, boring or chiselling them out, side by side, at all sorts of divergent curves, and sometimes at right angles one to the other, apparently in conformity with no plan, and carried on in accordance with the will of the excavator only, until they come so closely into relation with another series of workings that the divisions between them are not thicker than ordinary letter paper, when they instantly terminate, or turn aside, without in any known instance perforating the partition between the several galleries.—There is a considerable variety in the food of ants. A favorite article of diet is honey in some of its modifications, but more especially the secretions of the various species of aphides, known as honey dew, which is found besmeared the leaves of plants, and which is so injurious to the vegetables when it becomes thick enough to obstruct the pores; and it is on this account that wherever aphides abound, ants will ever be found attending on their motions. Some varieties of ants are in the habit of capturing root-

sucking aphides and imprisoning them in their cells, with a view to feeding on their honey dew. In this case the ants take the same care of the "root lice" as they do of their own young. Many ants subsist largely on decaying animal and vegetable matter, rendering themselves very serviceable as scavengers, and as assistants to the naturalists in the preparation and cleaning of the skeletons of small animals for museums. The allusion in Prov. vi. 6-8 to the habits of an Asiatic species, is also applicable to a Texan ant, *myrmica molefaciens*, which is reported by observers to not only feed upon a certain grain, the seed of *aristida stricta*, but also to plant, cultivate, and harvest it, laying it up in dry cells "against the rainy day." This species, sometimes called the "agricultural ant," builds "paved cities, constructs roads, and sustains a large military force." *Myrmica molestæ*, the "troublesome" or the "little red ant," is of a reddish yellow, the worker measuring only $\frac{9}{100}$ of an inch in length, and is the great pest of houses in many parts of the United States. In other places a large black ant (*F. Pennsylvanica*) takes its place, destroying decaying timbers, books, provisions, specimens of natural history, furs, and other property. Very small ants abound in South America, whose bite is so sharp that they are called fire ants; they are very annoying and destructive, making up in numbers what they lack in size.—Some species, especially the wood ant, *F. rufæ*, and the Amazon or warrior ant, *F. rufescens*, as well as the sanguinary ant, *F. sanguinaria*, are literally slave-holders. They sallie out in great swarms on belligerent and predatory excursions, for the purpose of capturing and bringing home to their own colonies the eggs and cocoons of other tribes, generally of the dusky ant, *F. fusca*, which, when hatched in the fortresses of the victors, are compelled to life-long labor. Independent of the annual migratory disposition of all the species, for the purpose of forming new colonies, sudden impulses, probably connected with facility of obtaining food, at times appear to seize on certain varieties of ants, leading them all to take wing simultaneously. Strange relations may be found in the "History of the Berlin Academy" for 1749, in the German "Ephemerides," and in the *Journal de physique* for 1790, of vast clouds of ants, darkening the air, and having a curious intestine motion, like that of the aurora borealis, unconnected with their line of flight, being seen at divers places, and, when they fell, literally covering the earth, so that one could not tread without crushing them at every footfall. For particulars concerning the habits and ravages of the great white ant of the tropics, see TERMITES, for that insect is not properly an ant. Du Chaillu has graphically described the formidable legions of the Cashikonay ant of Africa, before which all animals flee.—See the works of Baron de Geer and the younger Huber, Pack-

ard's "Guide to the Study of Insects" (Salem, 1868 *et seq.*), and Fitch's "Reports on the Insects of New York."

ANTACIDS, certain drugs used to neutralize acid, either in the alimentary canal or circulating in the blood. For the former indication, the carbonates and bicarbonates of soda and potassa, lime water, chalk, and magnesia with its carbonate, are used. The symptom which they temporarily relieve is, however, often more efficiently treated by regulated diet or by mineral acids. For the second purpose we have, besides the alkalies and their carbonates, including *littisa*, which is weight for weight the most powerful, the salts formed by them with acetic, tartaric, and citric acids. These acids, when in combination with alkalies, take up in the blood more oxygen, forming carbonic acid, which forms with the bases bicarbonates; so that the alkalization of the blood is attained without the local gastric troubles which might attend the administration of the caustic or carbonated alkalies in equivalent doses. The acetate of potassa, or corresponding salts, are largely used in the treatment of acute rheumatism where they render the urine alkaline. They also considerably increase its quantity.

ANTE, in ancient geography, a Sarmatian people, between the Dniester and the Don, a branch of the Slavic *Venedæ* or Wends. Justinian overcame them when he caught them in the Roman territory, and gave them new abodes on the other side of the Danube, that they might be a rampart against the Huns. From them Justinian took his title of *Anticus*.

ANTEUS, a mythological giant of Libya, son of Neptune and Terra, a mighty wrestler, and invincible while he continued in contact with the earth. Whoever visited Libya was bound to wrestle with him, and with the skulls of the vanquished, who were all slain, he erected a temple to Neptune. Hercules overcame him by lifting him off the earth, and strangling him in the air.

ANTALCIDAS, a Spartan, who, at the end of the Corinthian war, was sent on an embassy to Tiribazus, governor of Sardis, to negotiate a peace with Persia. He succeeded, and the peace, concluded in 387 B. C., with the concurrence of several Grecian states, was called after his name. It excited universal indignation throughout Greece, for Sparta had sacrificed to the Persian monarch the general interests of Greece in order to gratify her jealousy of the Athenians and Thebans. On being sent again to obtain the promised subsidies from the Persian king, he was tricked by the orientals, and fearing the popular indignation at home, he starved himself to death.

ANTAR, properly *Antarah*, an Arabian prince and poet of the 6th century, author of one of the *Moallakat*, the seven poems suspended on the Caaba at Mecca. A copy of a work called "Antar," celebrating the exploits of the prince, is in the imperial library of Vienna; and in the catalogue of the books written by Von

Hammer there is some account of this romance. The legends of his exploits appear to have been embodied in a book and considerably enlarged by Asmai or Osmay, at the court of Haroun al-Rashid. He appears to have been aided in this by Yohainah and Abu Obeidah. The copy translated by Mr. Terrick Hamilton, oriental secretary to the British embassy at Constantinople, was procured at Aleppo, and is comprised in a smaller form than any other as yet sent to Europe. The voluminous work had, it appears, been curtailed of many of its repetitions and much of its poetry by some learned inhabitants of Syria, and was therefore called the *Sham'iyeh* or Syrian *Antar*, in contradistinction to the original large work, which was called the *He-jaziyeh* or Arabian *Antar*. Though usually written in a continuous form, the story may very properly be divided into three parts. The 1st reaches to the marriage of *Antar* and *Ibla*; the 2d includes the period when the hero suspends his poem at Mecca; the 3d comprises the death of *Antar* and most of his comrades and relatives. Von Hammer, who twice read through the original, declared it to be "more interesting than the celebrated 'Thousand and One Nights,'" and Sir William Jones says: "I have only seen the 14th volume of this work, which comprises all that is elegant and noble in composition. So lofty, so various, and so bold is its style, that I do not hesitate to rank it among the most finished poems." With the Arabs it is a standard work. It is certainly one of the most ancient books of Arabian literature. Its language is uncommonly pure, equally remote from the harshness of the earlier or the conceits of the later authors.

ANTARCTIC DISCOVERY. The ancient geographers, among others the Greek Ptolemy, supposed a continent to exist near the south pole, and to extend to a great distance around it. On nearly all maps published before the middle of the last century, this continent is vaguely given as "Terra Australis Incognita." Captain Cook, by his second voyage, first threw doubt upon this theory. He was everywhere prevented by large masses of ice from reaching any high southern latitudes, and he could discover no land. In the few cases in which he passed beyond the Antarctic circle he reached only 61° 10' S. latitude. In 1819 the South Shetland islands were seen but not visited by Capt. William Smith, the commander of a merchant vessel, driven far to the south in trying to round Cape Horn. In 1821 Trinity land, lying S. of the South Shetlands, in about lat. 62° S., was discovered by Howell, an Englishman; Palmer's land to the westward of Trinity land, forming a part of the same coast line, by Palmer, an American; and still further to the south and west the Russian Bellinghousen found Alexander's land. Weddell, the next English explorer, made no discoveries of land, but reached lat. 74° 15' S. Enderby's land, lat. 67° 30' S., long. 50° E., and Graham's

bata), the tamanoir of the Portuguese, is about 4 feet long, with a bushy tail of 2½ feet more, the head being more than a foot long; the height at the shoulder is about 3¼ feet, and at the croup 5 inches less. The claws are 2½ inches long, sharp-pointed, with cutting edges, but so directed that they are comparatively useless as weapons of defence or offence, and applicable only to the motions of tearing down ant hills; there are 4 on the fore feet and 5 on the hind. The tongue may be protruded to the length of 18 inches. The hair is long and coarse, brown mixed with gray at the head, and with white on the body and tail; the throat is black, with a broad stripe of this color, bordered with a narrower white one, running over the shoulders to the rump; arms and thighs silvery white, and hind legs black; breast and under parts brown. The claws when not in use are folded against a callous pad in the palms and soles. Though large and powerful, it is very stupid and inoffensive, and allows itself to be overpowered by the meanest enemies, which it could easily hug and tear to death, did it know enough to exert its great strength. It is wholly terrestrial, unable to climb trees from the structure of the claws and the absence of prehensile power in its uncommonly plummy tail; it makes no burrow, covering its body when at rest by the tail, which, with its long mane, makes the creature resemble a bundle of coarse loose hay. The female has a single young one, which she carries on her back long after it can provide for itself. Its food consists exclusively of ants; it obtains them by tearing open the hills, and drawing its glutinous tongue over the insects, at the rate, it is said, of two protrusions in a second. The flesh of the ant bear is black and of a musky flavor, but it is eaten by the Indians and negroes, and at times even by the European colonists. It is a native of South America, from Colombia to Paraguay, and from the shores of the Atlantic to the foot of the Andes; but it is nowhere a numerous species, being rarely seen even in its native regions. Like all animals using a purely insect diet, it is capable of enduring a total deprivation of food for almost incredible periods.—The tamandua, *M. tamandua*, does not exceed the size of a large cat. Its head is less disproportionately long, but is of the same cylindrical form with that of the larger animal, with which also correspond the formation of its anterior and posterior extremities, the construction and number of its toes, and the shape and form of its claws. The most remarkable difference between the two animals lies in their tails, that of the tamandua, which is a purely sylvan animal, living exclusively in trees and never found on the ground, being bare on the inferior side and of singular prehensile power. The hair over the whole body of the tamandua is uniform, short, crisp, and shining, a sort of silky wool standing out from the body; and it varies much in color in different individuals. The female has but two pectoral mammae, and bears

but one young one at a birth, which is of a light straw color and very ugly. The tamandua feeds on termites, ants, honey, and even bees, which in those countries make their lives in the topmost branches of the forest trees, and are stingless. It is a native of tropical America.—The little or two-toed ant-eater, *Cyathurus didactylus*, is not larger than the common squirrel. It has but four toes on its hind feet, and two on the fore feet. Its whole length, from the snout to the insertion of the tail, is but 6 inches; the length of the head is not quite 2 inches, while that of the tail is about 9. In general form it resembles the tamandua, but its muzzle is shorter and less tapering. Its ears are short and drooping, and are nearly concealed among the fur, which is long on the head and cheeks. The hair on the body and sides is long, soft, and glossy, much shorter on the tail, of a uniform light straw color, tinged with maroon along the back, where it has a strongly marked line. The tail is bare of fur at the under surface toward the end, and is very prehensile. The ribs are very broad and flat, overlapping each other. It lives in trees, having many of the habits of squirrels; it feeds on the larvæ of wasps and other insects, which it picks out of their nests with great dexterity. Like other ant-eaters, it is nocturnal in its habits, being fond of sleeping by day with its tail securely twisted around a branch. It has four mammae, two pectoral and two abdominal, and bears but one offspring at a birth. Its native countries are Guiana and Brazil; further south it is unknown.

ANTELOPE, an animal of the family *antilopæ*, ruminating mammalia, with hollow horns, conical, bent back, cylindrical or compressed, ringed at the base. The occipital plane forms an obtuse angle with the frontal plane. The core of their horns is thin, consisting of a dense bone, often with a clear sinus at the base within. Teats two or four. Feet pits in the hind feet, and generally in the fore feet also. Perhaps the most certain characteristic of the antelopes is the cylindrical and annulated form of their horns, which are never angular, or provided with prominent longitudinal ridges, like those of the sheep and goats. They are also generally distinguished by having the lacrymal sinuses peculiar to the solid-horned animals of the cervine family, and possessed by the antelope alone of the hollow-horned ruminants, though not by all the species. In other respects, the different species of antelopes vary as widely as can be conceived. Many approach the deer so closely that the hornless females of the two families can hardly be distinguished apart; although the difference would appear on dissection, the true solid-horned deer being possessed of neither gall bladder nor gall duct, which belong to all the hollow-horned ruminants. They are the fleetest, as they are the most beautiful and most graceful of quadrupeds. They are, generally speaking, both gregarious and migratory, occasionally uniting in

vast herds. Africa is the headquarters of the antelope family in regard to variety, beauty, and numbers. Madagascar and Australia possess no antelopes; Hindostan and Further India have several varieties; western Europe and America each but a single species.—Originally, all

white, divided by coal-black lines; the common antelope of India, *A. cervicapra*; the madoqua, *A. saltrara*, the smallest of all horned animals, not exceeding a hare in size: the steinbok, the ourebi, the grysbok, the klipspringer, and the bush goat, with the red reed buck, the water buck, and the sable antelope, of southern Africa. The red reed buck (called rietbok in the Dutch settlements) is about five feet high and five long; its color is gray above and white beneath. The sable antelope, a very rare and beautiful animal, is one of the noblest types of the genus; its back and sides are black, and its belly white: its horns are more than three feet in length, and are covered with bold ridges.—Of the cervine antelopes, by far the most remarkable are the gemsbok, *oryx gazella*, and the oryx, *oryx leucoryx*. The former stands

Red Reed Buck (*Eleotragus arundinaceus*).

species of antelopes were referred to a single family; but they are now distinguished into two great divisions: the antelopes of the fields, whose nostrils are smooth and free from hairs, and the antelopes of the desert, which are bearded and have bristly muzzles. The antelopes of the fields are again subdivided into three groups: the true antelopes, which have a light, elegant body, slender limbs, small hoofs, short tails, lyrate or conical horns, placed above the eyebrows; the cervine antelopes, with short, deer-like bodies, strong, slender limbs, long tails, cylindrical at the base, with the hair longer at the ends, and muzzles like those of the cervine ruminants; and the goat-like antelopes, which have a short heavy body, strong hoofs and false hoofs, very short tail, flat and hairy above, and recurved conical horns.—Of the true antelopes, the most remarkable are the gazelles of Egypt, Barbary, and Turkey in Asia; the Ariel gazelle of Egypt and Kordofan; the pallah, *antilope apyceros melampus*, of southern Africa, with its annulated, lyrate horns, and its sleek hide, painted with brilliant rust color and

Addax nasomaculatus.

$3\frac{1}{2}$ feet high at the shoulder, with long straight horns, annulated at the base. His hide is of a deep blue-gray above and snow-white below, divided by marked lines of jet black. Even the lion seldom dares attack him. The oryx is a native of Nubia and Senegal. Another cervine antelope, not far inferior in size to the last, is the addax of Senegal, which has preserved its name unaltered since the days of Pliny. A

Sable Antelope (*Aligocerus niger*).

Siberian Antelope (*Saiga Tartarica*).

species less familiar than either of those just named is the Siberian antelope (*saiga colus* or *Tartarica*), an animal inhabiting the region of the Caucasus, northern Persia, and Siberia. It is of medium size, resembling a deer in form, and has a peculiarly curved forehead and face. Its horns are of a light color and semi-transparent, and are much valued. The animal is gregarious and migratory in its habits.—Of the goat-like antelopes there are several of the oriental species; but the two most conspicuous are the European chamois, or antelope of the Alps, *rupicapra tragus*, resembling a goat without a beard, with short erect horns, suddenly curved backward at the tip, and coarse hair, beneath which lies a close coat of wool (see CHAMOIS); and the American prong-horn, *A. americana*, which has considerable affinity to the chamois; its horns only differ from that

Prong-horn (American antelope).

antelope's in turning inward at the tip, and in having a short anterior, medial prong. The winter coat of this antelope differs from that of any other known animal; the hairs, which stand out to the length of two inches at right angles to the body, being tubular, like the quills of a bird, and nearly as brittle as glass. This antelope is fully described in Dr. Richardson's *Fauna Boreali-Americana*.—The antelopes of the desert are divided into two groups, the equine antelopes and the bovine antelopes. Of the equine antelopes there are but two species: the gnu, *A. gnu*, of South Africa, called the *wildebeest* by the Boers, which is nearly of the size of the ass, and has precisely the body, neck, mane, tail, and paces of a small horse, with the limbs, hoofs, and horns of an antelope; and the brindled gnu or gorgon, *cato-blepas gorgon*, called by the Boers the *blaur wildebeest*, of the same country. (See Gnu.) The bovine antelopes are the *A. bubalis* of northern Africa, equal in size to the largest stag, called by the Arabs *bekker-el-rash*, or the wild ox, the hartebeest, the blesbok, the bontebok, and the sassabee of southern Africa; the korrigum of Senegal; and the doria, or gilded antelope, of western Africa.—To these, which complete the list of antelopes as scientifically distinguished, may be added the highly interesting group of *strepsicera*. This

group of antelopean ruminants includes the koodoo, *strepsiceros kudu*, which is fully 4 feet high at the shoulder, with horns nearly as long as the male is high, reflected in a beautiful sweeping spiral of $2\frac{1}{2}$ turns; the eland, *oreas canna*, which is as large as a horse, weighs from 7 to 9 cwt., unlike most antelopes is always fat, and is said to furnish meat superior to beef (see ELAND); and the great nil-gbau, *portax tragocamelus*, one of the largest of antelopes, having much the character of the ox, with the horns, head, and muzzle of an antelope, the flat compressed neck of a horse, with a thin erect mane, increasing into a tufted bunch on the shoulders, and a singular beard-like tuft of stiff hair growing out of the middle of its throat, peculiar to itself alone. Its fore legs are somewhat longer than its hind ones, and its withers rise so much as to give it the appearance of having a hump. Its color is deep slaty blue, with a white spot on each cheek, and a large white patch on the throat. It is a native of the deep forests of India, where it is a vicious and dangerous animal, but it has been taken to England, where it lives and breeds.

ANTENNE, horn-like members on the head of insects and crustacean animals. The antennæ are commonly called feelers, but their functions are not understood. In insects they are two in number; in crabs and lobsters there are more than two. The antennæ of insects are usually composed of minute articulated rings, containing nervous threads, muscles, tracheæ, and cellular tissue, forming organs of sensation, motion, and respiration. In most orders the articulations amount to 10 or 11 in number, although they are much fewer in some species, while in others they reach even to 150. The length of the antennæ does not depend on the number of articulations, as they are often long when of only three or four pieces, and the reverse. They are inserted on the front of the head in the region of the eye, and connected by means of a ball and socket. The distinction of sex in some species is marked by the peculiar formation of the antennæ. In moths the antennæ of the male are of more simple construction than those of the female. In moths and beetles they are much longer than the body, while in the common house fly they are comparatively short. Linnæus and Bergman supposed them to be organs of touch, and they were thence termed feelers; but M. Straus-Dürckheim is of the opinion that the antennæ are the insect's organs of hearing. Professor Bonsdorf, of Abo in Finland, and other naturalists, have adopted the same opinion. The younger Huber attributed to ants the use of the antennæ in a sort of language, which he terms the "antennal language," understood not only among ants themselves, but also among the aphides, which furnish the honey-dew on which ants feed.

ANTENOR, a Trojan prince, son of Æsyetes and Cleomestra, and one of the wisest among the elders of Troy. He counselled his fellow

citizens to give Helen up to the Greeks. It is said that, having been sent to negotiate for peace with Agamemnon, he concerted with him and Ulysses a plan for delivering up the city; and when Troy was taken the skin of a panther was hung up at his door as a signal to the Greeks to spare the house. According to some authorities, he afterward founded a new kingdom at Troy on the ruins of the old one; according to others, he settled at Cyrene or on the W. shore of the Adriatic.

ANTEQUERA (anc. *Antiquaria* or *Anticaria*), a city of Spain, in the province and 25 m. N. by W. of Malaga, with which it is connected by railroad, on the Guadalorce; pop. 25,900. It is situated in a fruitful valley, surrounded by lofty mountains containing numerous marble quarries, and has many churches and convents, and some remains of antiquity. While the Moors held the kingdom of Granada this city was a fortress of great importance, and the possession of it was constantly contested. A Moorish castle, built on Roman foundations, still exists in the upper part of the city. The inhabitants are chiefly employed in agriculture and the manufacture of cloth, leather, paper, silk, and cotton.

ANTHELMINTICS. See Entozoa.

ANTHEMUS. I. Emperor of the West from A. D. 467 to 472. He was the son-in-law of the emperor Marcian, and was invested with the purple at the suggestion of Ricimer, who ultimately became his son-in-law. Anthemius and Ricimer soon quarrelled, however, and then the latter, proclaiming Olybrius emperor, laid siege to Rome. The city was taken by storm, and Anthemius was slain. II. An architect and mathematician of Tralles in Lydia, who flourished in the 6th century. He designed for the emperor Justinian the plan and commenced the building of the church of St. Sophia. A fragment of one of his mathematical works was published at Paris in 1777.

ANTHER (Gr. ἀνθηρῶς, flowery), the male organ of the flower. Considered morphologically, it is a modified leaf, the petiole or stem of the leaf becoming the filament of the stamen, and the leaf blade by the separation of its two surfaces forming two theca or lodges containing pollen, the midrib of the leaf becoming the connective of the anther. The filament may be absent, when the anther is said to be sessile; and it may be inserted on the style, as in orchids (in the Linnæan class *gynandria*), or on the corolla. Several filaments may be more or less united, sometimes forming a tube around the style, as in *malvaceæ* (class *monadelphia*); sometimes a split tube with a single detached filament, as in *leguminosæ* (class *diadelphia*); sometimes the tube is split into several portions, forming clusters of stamens (class *polyadelphia*). The filaments may differ in length in the same flower, as two short and two long (class *didynamia*), or two long and four short (class *tetradynamia*). The number of stamens characterizes 13 classes of the Linnæan system, which is now wholly abandoned by botanists.

The attachment of the anther to the filament varies. Sometimes the connective is only a prolongation of the filament (adnate anther), which may extend far beyond the anther, as in the oleander. If the filament joins the connective at its centre, it may balance the anther if the connective is linear, in which case the anther is said to be versatile; or if the connective is shield-like, bearing several pollen lodges on its lower edge, it is called peltate. Lilies present an example of the first, and in tulips the connective has a funnel-like hollow in which the filament is fixed; and the juniper, cypress, &c., show the peltate form. The anther appears in the flower bud before its filament as a gland-like excrescence. The two cells on either side the connective often subdivide into four; but as the development progresses the septum disappears and the anther becomes bilocular, or even, by the removal of the connective, unilocular. The lodges are cylindrical, globose, ellipsoidal, cordate, kidney-shaped or hastate, or even, as in the squash, undulating or twisted. The surface may be smooth, or downy, fringed, and bearded, as in lobelias. Anthers may be united in the same way as the filaments, as in *composite* (class *syngenesia*), or they may be suppressed or abortive on some of the filaments. From their position on the connective, they are said to be introrse when the lodges face the style, or extrorse when they are directed outward, which is the more common position. When the pollen is ripe the anther opens, either by pores at the base or apex (and these pores are sometimes at the end two tubular extensions of the lodges), as in the potato and melastoma; or by valves, as in the barberry; or, what is most common, by clefts or sutures on the edge corresponding to the edge of the typical leaf. After the discharge of the pollen the anther collapses, and, if of a yellow or orange color when full, becomes a dark orange-brown.

ANTHON, Charles, LL. D., an American classical scholar, born in New York in 1797, died there, July 29, 1867. His father, Dr. G. C. Anthon, a German by birth, was surgeon general in the British army, and soon after the revolution settled in New York. Charles graduated at Columbia college in 1815, and in 1819 was admitted to the bar. The next year he was appointed adjunct professor of languages in Columbia college. In 1830 he produced his large edition of Horace. In that year, also, he became rector of the grammar school attached to the college, and in 1835 he succeeded Prof. Moore as head of the classical department of that institution. For many years it was his constant custom to retire at 10 and rise at 4, so that a large part of his day's work was done by breakfast time; and thus he produced some 50 volumes, consisting chiefly of editions of the Latin classics and aids to classical study, and including a Latin lexicon and a "Dictionary of Greek and Roman Antiquities." All his works were republished in England. When

first made rector of the grammar school, he conferred on the public schools of his native city six free scholarships.

ANTHONY, Henry B., an American journalist and senator, born at Coventry, R. I., April 1, 1815. He was educated at Brown university, became in 1838 editor of the "Providence Journal," was governor of Rhode Island in 1849 and 1850, and declined a reelection in 1851. In 1859 he was elected United States senator as a republican, succeeding Philip Allen, a democrat; was reelected in 1864, and again in 1870. He was a delegate to the Philadelphia convention of 1866, and president *pro tempore* of the senate for some time in 1869 and 1871.

ANTHONY, Saint. I. Surnamed the Great, born in Upper Egypt in 251, died in 356. He was rich and well educated, but sold all his possessions, gave the money to the poor, and retired into the desert, where he spent a great many years in ascetic solitude. At the age of 54 he was persuaded to become the director of a number of anchorets who wished to enjoy his instructions. They dwelt in detached cells in Fayoom, near Memphis, and from this establishment dates the foundation of the monastic system. St. Anthony twice left his retreat and visited Alexandria: once during the persecution by Maximian in 311, when he hoped to obtain the crown of martyrdom; and again in 355, to support his friend Athanasius against the Arians. During his seclusion he is said to have neglected ablutions, clothed himself simply in a hair shirt, and fought with devils. He was reported to have cured a cutaneous disease known before his time as the "sacred fire," but afterward as St. Anthony's fire, and later as erysipelas. On this tradition an order bearing his name was founded (1095) for the care of patients with this disease by Gaston, a rich French nobleman, at St. Didier-la-Mothe, in gratitude for a supposed cure wrought on his son by the reputed bones of the saint. **II.** Of Padua, born in Lisbon, Aug. 15, 1195, died in Padua, June 13, 1231. He was one of the leaders of the newly established order of Franciscan monks, and, desirous of martyrdom, embarked for Africa, was shipwrecked on the coast of Italy, and preached with wonderful eloquence and success in the cities of Montpellier, Toulouse, Bologna, and Padua. He was canonized by Pope Gregory IX. in 1232, and is honored especially in Portugal and Italy.

ANTHONY, Susan Brownell, an American reformer, born in South Adams, Mass., Feb. 15, 1820. Her father was a member of the society of Friends. She was employed in his cotton factory, completed her education in a school at Philadelphia, and from 1837 to 1852 was a teacher in the state of New York. She became interested in the cause of temperance, and an admission to a convention being denied to her on account of her sex, she called a convention of women (1849), and since that time has been conspicuous in various philanthropic and reformatory movements. She has identified

herself especially with the agitation for female suffrage, in the interest of which she has visited many parts of the United States, and delivered numerous lectures and addresses. In 1868 she founded in New York a journal called "The Revolution," which she conducted for some time in conjunction with Mrs. Elizabeth Cady Stanton and Parker Pillsbury. She has acted on several occasions as delegate of the New York working women's association.

ANTHRACENE (C₁₄H₁₀), formerly called parannaphthaline, a solid hydrocarbon which accompanies naphthaline in the last stages of the distillation of coal tar, and which has acquired great importance as the material from which artificial alizarine is now manufactured. In an experiment made on a large scale it was found that 100 tons of tar yielded 0.63 ton of anthracene, or one ton of anthracene can be obtained from the distillation of about 2,000 tons of coal, not reckoning the quantity of anthracene contained in the pitch. The preparation of anthracene is conducted as follows: The semi-fluid product of the fractional distillation of coal tar, commonly called green grease, is placed in a centrifugal machine in order to expel mechanically as much as possible of the oil, and the residue is pressed between hot plates. The crude material is carefully distilled, rejecting the portion which comes over between 340° and 350° C., and the portion remaining in the retort is exhausted with rectified petroleum at a boiling heat, filtered, and cooled. The crystalline mass is expressed and the entire operation repeated several times. On recrystallization from alcohol, the nearly pure anthracene is obtained in rhomboidal plates. If these be carefully sublimed, a chemically pure product is obtained. Pure anthracene occurs in bluish-white foliated crystals, having a beautiful violet fluorescence. These crystals are rhomboidal tables. A little above 200° C. it melts to a limpid liquid, which becomes rapidly dark-colored. It is not perceptibly volatile at 100° C., but between 210° and 220° C. it sublimes easily, yielding a fetid and irritating vapor. Distilled at 350° C., it is partially altered. It is quite soluble in boiling alcohol, and in light naphthas, from which it crystallizes out on cooling. Heated slightly with fuming sulphuric acid, it dissolves gradually, giving a greenish solution of the sulphanthracene acid. The green color appears to be due to a trace of nitrous compounds of the acid. Nitric acid attacks anthracene violently, and chlorine and bromine act upon it, yielding substitution products. Anthracene has been made artificially from toluole and from benzole.—The chief use of anthracene is in the artificial production of alizarine. Several patents have been taken out for this purpose by Gräbe and Liebermann, who were the original discoverers in 1869 of the methods of its manufacture. (See ALIZARINE.)

ANTHRACITE (Gr. *ἀνθρακίτης*, like coals, from *ἄνθραξ*, coal), the most condensed variety of

MAP OF THE ANTHRACITE REGION OF PENNSYLVANIA

BY S. HARRIES DADD

EXHIBITING ITS RELATIONS TO THE PRINCIPAL MARKETS.

ENGINEER OF MINES, &c.

fields and connected with the bituminous coal beds of the Alleghany field, designates the lowest workable and consistent bed as A and the highest as N. But this nomenclature denotes series or groups of coal beds, rather than single beds. Fig. 1 presents the general type of the Pennsylvania anthracite strata. The figures in the column and in connection with the letters indicate thickness in feet. A number of small unworkable seams are not here represented. The 15 groups from A to N include 30 beds above 2 ft. thick and 20 seams less than 2 ft. This mode of grouping the beds in the anthracite fields was suggested by the natural divisions of massive sandstone and conglomerate strata in the coal measures, and the frequency with which some of the prominent groups united as a single bed or divided into two or three beds. In the southern anthracite field of Pennsylvania a few imperfect, irregular, and impure "nests" or pockets, rather than beds, of graphitic anthracite are occasionally found below A; but these local deposits have no general horizon, and are valueless for commercial purposes. Though pockets of good

FIG. 1.—ANTHRACITE STRATA

coal are sometimes found from 5 to 20 ft. thick, they vary to as many inches, and do not exist as regular and consistent beds. A is usually a small bed of red-ash coal, but two or three thin seams are frequently found in this group which exist in the conglomerate, or close to it, everywhere. The coals of A generally contain from 10 to 20 per cent. of earthy matter, and are seldom workable. B is generally a large bed from 10 to 30 ft. thick, but frequently two beds of 5 to 10 ft. each. The lower part produces red-ash coal, and the upper gray or pink. The coal is excellent, and valued for blast furnaces, though it contains more silica than the coal of any other workable bed higher in the measures. C is usually a group of small unworkable beds, producing white or gray-ash coals. D is a single bed of pure white-ash coal, generally from 5 to 10 ft. thick. E is the celebrated mammoth, which is a single bed from 20 to 70 ft. thick in some localities, and a group of two and three in others. The coal is always of the white-ash variety, and is hard, dense, pure, and lustrous. Fully eight tenths of the present anthracite production is from this group. F is composed of two small beds of white-ash coal, and is not of much value; it is often known as the "rough vein." G is generally a large bed from 7 to 10 ft. thick, and always a single one, though the lower stratum produces white-ash and the upper pink or gray-ash. It is locally known as the gray-ash or primrose vein, and is supposed to be identical with the Pittsburgh bed in the bituminous field. All the workable beds, from A to G inclusive, produce blast furnace coal; but the coals of the beds from G to N are less dense and contain less carbon and more volatile matter than the lower coals, and crumble under a high temperature. They are therefore not used for steam and furnace purposes generally, but are much valued for household uses, excepting large furnace heaters. They evolve an intense heat, and are free-burning, but will often "clinker" under a strong draught. In the preceding analytical table the highest percentage of carbon is 94.10 (No. 6), which is a hand specimen from the mammoth bed, E, in the Pottsville district; but it is a well known fact that the mammoth coals of the Lehigh district are equally as pure and generally more dense than any other anthracite. The average, therefore, of Nos. 1, 2, 3, 4, and 6 will give the mean of the hardest and purest anthracite; while No. 5 (M) is a type of the upper coals, and approaches the limit of the true anthracite, as shown by 7 and 8, which are semi-anthracite and semi-bituminous. The density and hardness of the coal decrease from A to N in the ascending order, while the volatile matter increases from N to A in the descending order; and the proportions of carbon increase and decrease in the same ratio and order. The coals of the lower beds are most hard and dense. The middle beds produce the purest coal, and the coal of the upper beds is most soft and friable under heat. The

same description would apply to the general decrease of carbon and increase of volatile matter in these coal beds from east to west. There is a gradual decrease also in the dimensions of the beds in the same direction. The same gradual change from hard anthracite to semi-anthracite and bituminous is as marked a feature in the South Wales (English) coal fields as in the Pennsylvania coal fields. The general features and fractures of hard anthracite are peculiar and noticeable to the common observer. They are massive, hard, dense, amorphous or conchoidal in fracture, with fine, sharp edges when broken, and a rich satin or an iron-black sub-metallic lustre. With some local exceptions, the softer varieties, both red and white-ash, are less massive, hard, and dense, more regular and cubical in fracture, and, exclusive of the upper red-ash beds, less rich and lustrous.—The prominent anthracite fields of the world are those of Pennsylvania and South Wales, which produce nine tenths of the quantity used. The developed coal fields of the world embrace an area of about 350,000 sq. m., of which over 300,000 are in the United States, exclusive of lignite. (See COAL.) About 2,000 sq. m. of this entire area contain anthracite, of which half is in the United States, including the somewhat doubtful New England coal fields. The entire coal production of the world in 1871 was between 225 and 250 million tons, of which England produced 110 millions and the United States 41 millions. About 20 millions of the entire amount was anthracite, of which 15 million tons were produced in Pennsylvania, and the remainder in South Wales, France, and other countries.—The South Wales coal field lies on the northwest of the Bristol channel, extending from St. Bride's bay in the east to Pontypool

FIG. 2.—Group of Pennsylvania Anthracite Basins.

in the west, a distance of 90 m., with a maximum breadth of 60 m. Its mean breadth is less than 20 m., presenting an area of about 1,500 sq. m., of which only 1,000 contain workable coal beds. It is divided by an axis parallel to its strike, and divided also into numerous intermediate basins, while the measures undulate both from E. to W. and from N. to S. The deepest part of the field is supposed to be 8,000 ft. Most of the mining has been done by "drifts," and but few shafts had been sunk to any great depth up to 1864. Twenty-three workable seams exist in the principal basins, averaging altogether 92 ft. of coal. Of these, 12 are from 3 to 9 ft. thick, and 11 from 18 in. to 3 ft. Besides these there are numerous smaller seams from 6 to 18 in. thick. On the N. side of the field the coal is anthracite in character, and resembles the anthracites of Pennsylvania, though generally containing more hydrogen or volatile matter; on the E. or N. E. the coal is semi-bituminous, and is used extensively, both raw and coked, in the blast furnaces of the region. On the S. side the coal is of a bituminous character. The change from anthracite to semi-bituminous and bituminous is gradual, and much the same in its metamorphic phases as we find existing in the coal fields of Pennsylvania. There are 16 thin seams of ironstone interstratified with the coal; the general yield of this ore is not over 30 per cent. of metal in the furnace. The coal production of South Wales in 1854 was 8,550,270 tons; of this amount only 1,000,000 tons was anthracite, the total being the products of 245 collieries.—The anthracites of Pennsylvania exist in four parallel coal fields, in the counties of Schuylkill, Carbon, Columbia, Northumberland, and Luzerne, embracing an area of 470 sq. m. Within these fields numerous parallel basins or synclinal troughs are formed by the peculiar undulations of the strata, which dip at every angle from horizontal to perpendicular. Fig. 2 represents the general grouping of the principal basins of the southern Pennsylvania anthracite field, and the eastern part of the middle field, without reference to local peculiarities and abrupt dips.

Coal was discovered in the Wyoming valley soon after its settlement, but the first authentic

account which we find of the use of anthracite in the United States was in 1768-'9, when it was used by two blacksmiths from Connecticut named Gore. One of these brothers, Jude Obadiah Gore, related the facts to Judge Jesse Fell of Wilkesbarre, who subsequently communicated to Silliman's "Journal" and Hazard's "Register." In 1776 coal was quarried from the Baltimore bed near Wilkesbarre and the Smith mine near Plymouth, and taken down the Susquehanna in arks to the government arsenal at Carlisle. This trade was continued during the revolutionary war, and anthracite was used by the blacksmiths and gunsmiths of the lower Susquehanna from that time forth; but from the difficulty of making it burn it was not used for domestic purposes till 1808, when Judge Fell succeeded in burning "stone coal" in a grate of his own construction. Anthracite was sold in the vicinity of Wilkesbarre to the smiths at \$3 a ton, and in Marietta, on the lower Susquehanna, at \$8 to \$9 a ton from 1810 to 1814. This was probably the first successful use of anthracite for general purposes in the world. The earliest record of the production of anthracite in France, as given by Taylor, is in 1814; while Mr. Blakewell, an English geologist, says the Welsh coals were "inferior" and not used for domestic purposes in 1813, and but "little used" in 1828.—The northern or Wyoming coal field is naturally divided into two regions, the Lackawanna and the Wyoming, and these into several districts. The Lackawanna region includes the districts on the Lackawanna creek, which empties into the Susquehanna at Pittston. The districts are the old or original Lackawanna, at and around Carbondale, the Seranton, and the Pittston. Around these centres the early developments of the Lackawanna region were made, and collieries clustered. The Carbondale district was opened in 1829 by the Delaware and Hudson company's canal and railroad; the Seranton district by the Delaware, Lackawanna, and Western railroad, in 1854; and the Pittston district by the Susquehanna canal in 1843, and the Pennsylvania coal company's railroad in 1850. The production of the Wyoming or northern coal field in 1871 was 6,481,171 tons. Of this amount 2,867,598 tons was sent from the Wyoming region, and 3,613,573 from the Lackawanna. There are now (1873) nine railroads and two canals employed in transporting coal from these regions. The coal beds in the Wyoming portion extend to K (fig. 1), but in the Lackawanna the number is less, extending only to H or I. The coal of the entire field is anthracite.—The first or southern and middle anthracite fields are the next in size and importance, and in order of development. Their topography and geology differ materially from the northern field, as shown by fig. 2 from Lesley. The valleys in which the coal exists are comparatively narrow, while both anticlinals and synclinals and the strata of the measures are more abrupt than those of the former.

This field terminates in the east on the Lehigh river, in a single point or synclinal trough. In the west are two terminal points or prongs, which are wide apart at their extremities near the Susquehanna. Its extreme length is 73 m. to the end of the Dauphin or south fork, and 10 m. less by the Lykens Valley or north fork. Its mean breadth is 2 m., and its maximum, at Pottsville, 5 m. The number of coal beds is greater in this than in any of the other anthracite fields. The coal of the E. end is hard anthracite; of the Lykens Valley fork, semi-anthracite; and of Dauphin fork, semi-bituminous. The middle anthracite field is divided longitudinally by the Locust mountain anticlinal, over which the coal beds connect at several points. It is divided into two regions. The Mahanoy region is 25 m. long, with a mean breadth of nearly 2 m. Its basins are narrow and deep, and the strata abrupt. The Shamokin or northern part, not shown in fig. 2, is 20 m. long, with a mean breadth of 2½ m. The basins are wider, of less depth, and the strata of less inclination, than the former. The highest bed in this field is K. The coal is generally anthracite, except at the W. extremity, where it is semi-anthracite. The earliest records we find of the existence of coal in the southern and middle coal fields are those on Seul's map of Pennsylvania and Faden's "Atlas of North America" (1810-'17). The first discovery for practical purposes, however, was made in 1791 by a hunter named Philip Ginter on the Lehigh end of the southern coal field, and on the site of the since famous Lehigh coal quarry at Summit Hill. In the following year the "Lehigh Coal Mine Company" was formed by Robert Morris, J. Anthony Morris, Cist, Weist, Hillegas, and others, who secured 6,000 acres of land and opened the quarry the same year (1792) to test the character and value of the coal. In 1798 a charter was obtained by this company for a sluice navigation on the Lehigh, and in 1803 six arks with 600 tons of coal, from the Summit Hill quarry, were started down the river; but only two, with less than 100 tons each, reached Philadelphia. The city authorities purchased the coal to supply a steam engine used at the water works, then in Broad street; but it could not be made to burn, probably because it was tried in large lumps, and was broken up to gravel the walks of the grounds. In 1806 another ark load was taken to Philadelphia with no better success. It appears, however, from a brief account of "The Discovery of Anthracite on the Lehigh," in the memoirs of the historical society of Pennsylvania, written by Dr. T. C. James of Philadelphia, who had visited the mines, that he had commenced using stone coal in the winter of 1804, and, having laid in a supply from this and the former cargoes, continued to use it to the day of publication in 1826. About this time (1800) William Morris, whose mines were near Port Carbon, Schuylkill county, took a load of coal to Philadelphia, but did not succeed in selling

or bringing his new "stone fuel" into notice. In 1814 two arks of coal reached Philadelphia, of five which were started from the mines, and these two cargoes were sold to Messrs. White and Hazard at the Schuylkill Falls wire manufactory, at \$21 per ton. But previously, in 1812, Col. George Shoemaker of Pottsville had taken nine wagon loads of coal from his mines at Centreville, near Pottsville, to Philadelphia, and had disposed of two loads at the cost of transportation to these gentlemen, who desired to succeed in using it at their manufactory. Mr. White and his firemen spent half a day in the attempt to burn it without success. At noon they closed the furnace doors and went to their dinner in disgust with "stone coal;" but on their return they were astonished to find the doors red-hot and the furnace in danger of melting. Since then anthracite has been a desirable and eminently available fuel for all purposes. Col. Shoemaker, however, had disposed of the other seven loads to others who did not succeed in making the coal burn, though this was the free-burning red-ash variety, and they obtained a writ from the city authorities for his arrest as an impostor and swindler, who had sold them rocks for coal. The Lehigh navigation was improved in 1820, and during that year 365 tons of anthracite—which heads the column of the trade—was sent to Philadelphia and sold at \$8 50 a ton. From this time the anthracite trade has steadily increased. Previous to 1847 most of the Lehigh coal was obtained from the open quarry in the mammoth or E bed (not an accumulation of beds, as is generally supposed), on the spot where the coal was first discovered. In 1847 about 2,000,000 tons had been sent from this quarry, and 30 to 40 acres had been excavated from the bed, which is here 50 ft. thick. Since this date the quarry method has been abandoned for regular mining operations by tunnels and slopes. The original "Coal Mine Company" leased in 1817 their whole property and privileges to Messrs. White, Hazard, and company, for 20 years, at an annual rental of one ear of corn! but they were bound to deliver for their own benefit 40,000 bushels of coal annually in Philadelphia. These gentlemen formed their interests into a stock company—the "Lehigh Coal Company"—and also organized the Lehigh navigation company, afterward incorporated as the Lehigh navigation and coal company, and subsequently changed to the Lehigh coal and navigation company. The stock of the old coal mine company was bought up by the new organization. At first the shares, representing 50th parts of the whole property, were bought at \$150 each; the last brought \$2,000. The number of tons shipped by the Lehigh canal in 1871 was 740,630, and the total amount by canal from the commencement of the trade is 26,139,540 tons, of which, however, a considerable portion was mined in other regions. The Schuylkill canal was projected in 1814, and so far completed in 1822 that 1,480 tons were shipped over it to Philadelphia.

Since then 28,700,015 tons have passed through it, of which 1,010,171 tons were shipped in 1871. The first railway built in the United States, except one of three miles at Quiney, Mass., was a gravity road from the Lehigh quarry at Summit Hill to the canal at Mauch Chunk, a distance of 9½ m. This was used from 1827 to 1872 for the transportation of anthracite; but on the completion of the Nesquehoning tunnel through the Locust mountain the old gravity line was abandoned as a coal road, and is now devoted to pleasure excursions, for which it has long been famous on account of the novelty of the ride and the picturesque grandeur—sometimes beauty—of the rapidly changing scenes. The view from the top of Mt. Pisgah, which towers over the waters of the Lehigh, is remarkably wild and grand. The numerous railroads built as feeders to the Lehigh and Schuylkill canals and the principal trunk lines will be found in an accompanying table. The Philadelphia and Reading railroad, opened from Pottsville to Philadelphia in 1841, had transported 62,128,735 tons of anthracite up to 1872, of which 4,584,450 tons were shipped during 1871. The Lehigh Valley railroad was opened from Mauch Chunk to Easton in 1853, and transported 2,889,074 tons in 1871, and a total of 22,981,252 since its completion. This line has since been extended through the Wyoming valley and into the state of New York, on the line of the Susquehanna river. The Lehigh and Susquehanna railroad, opened from the head of navigation on the Lehigh into the Wyoming region in 1846, was extended to Easton as a great trunk line in 1867, and during the next year 1,058,054 tons were transported over it. The term "Lehigh coal region" originally designated only that portion of the southern anthracite field which extended from Tamaqua to the Little Schuylkill to the Lehigh river; but since the completion of the Beaver Meadow and Hazleton feeders to the main line of canal the name has been applied to all the small middle basins, of which there are six, though three of these—the Little, Big, and Lower Black Creek basins—are on a tributary of the Susquehanna, and cannot properly be termed Lehigh basins. They produce a hard, dense, amorphous coal, resembling the original Lehigh coal in both feature and character. The geology of these small basins is similar to that of the E. end of the southern and middle anthracite fields. They are long, narrow, canoe-like troughs, nearly parallel in strike with themselves, and with the larger fields to the south, north, and east. The upper productive coal bed in these small basins is E. No. 3 in the preceding analytical table represents the general type of these basins. The small percentage of ash, however, is an exception.—The number of collieries in these anthracite regions in 1871 was 437, and their entire production, including home consumption (not in the tables), was 17,000,000 tons; and 52,227 men and boys were employed in and about the mines.

TABLE OF ANTHRACITE PRODUCTION IN PENNSYLVANIA.

general formation of the beds resembles that of the lower irregular beds or pockets in the southern Pennsylvania field below A; and the impure, graphitic character of the coal is the same. In both the coal exists in "nests" rather than beds, sometimes 10 and even 20 ft. thick, but often not as many inches, and frequently they disappear entirely. In the Pennsylvania anthracite fields the paleozoic sedimentary strata, between the coal measures and the igneous rocks, are between 5 and 7 m. in thickness; while the sedimentary strata below the New England field are comparatively thin, and so highly crystallized or metamorphosed by heat as to have been mistaken by the early geologists for the gneissic rocks. Dr. Edward Hitchcock, however, maintains that the whole region, embracing not less than 500 sq. m., is a true coal field, which has experienced more than ordinary metamorphic action both mechanical and chemical. He says: "The mechanical forces seem to have operated on the strata containing the coal in a lateral direction, so as not only to raise them into highly inclined positions, but also to produce plaits or folds. . . . The chemical metamorphoses which these rocks have experienced consist mainly in such effects as heat would produce." Prof. Silliman, Prof. Jackson, and Dr. Hitchcock have given favorable opinions in regard to the probable future productiveness of this field and the commercial value of the coal. The developed coal beds are three in number. Their dimensions are variable, but may be averaged from 3 to 7 ft. respectively, when in their best condition. At Portsmouth the principal bed has been mined by a slope of 600 ft. in length, inclining at 30° to 35°, to a vertical depth of 300 ft.; from the

bottom of which gangways were driven 1,000 ft. in length on the strike of the bed, which increased and decreased from 16 inches to as many feet. Mining operations have been attempted in many localities in this field, but all have ended in failure, owing to the disappearance or faulty character of the coal beds. The amount of coal mined from the field has been insignificant, and no trustworthy statistics have been re-ordered. The product, however, when pure and solid, compares favorably with the Pennsylvania anthracite, though usually the best of it contains more water, graphite, and earthy impurities. It is probable that deep and well conducted mining operations will eventually develop this field in a remunerative manner. The diamond drill can now be used before incurring the cost of pits and mining operations, and it may reasonably be anticipated that purer coal and more regular beds will be found at greater depth.—The Virginia anthracite field, which may be appropriately termed the New river coal field, in Montgomery and Pulaski counties, in S. W. Virginia, consists of two narrow, parallel basins on Price's and Brush mountains. Price's mountain is a narrow, short synclinal ridge, which rises in the Silurian limestones of the great valley range, and is part of the watershed between the James and New rivers. In this ridge the coal is enclosed as a narrow trough or basin, with an eastern dip of 30°, while the true western dip is inverted and dips E. at an angle of 80° or 85°. Thus the bottom slate of the lower bed is the roof of the upper bed, and the basin may be generally represented by an Italic capital V; but the force which tilted and folded the strata in this inverted manner distorted the coal measures and crushed and ruined a large part of the coal, while slips and other forms of fault render the operations of mining

* This table is from official sources, excepting the Morris and Essex and the Central railway of New Jersey, which were not built exclusively as coal transportation lines.

in this basin uncertain and precarious. The coal of Price's mountain basin is a true anthracite, but less dense, lustrous, and pure than that of Pennsylvania. The Brush mountain basin lies at the E. base of the North mountain, and resembles the opposite Price's mountain basin in lithological structure; but the inverted strata of the W. side have been destroyed, except in a few localities, by erosion. In some few places where the inverted strata exist in this basin, they are folded back, so that the coal beds, which in their normal condition must have dipped to the west, are now lying on their opposite dip, and the strata of the entire basin in such localities dip east, abutting abruptly against the underlying sandstones or limestones. The coal of this basin is semi-anthracite. Coal has been mined in a small way from numerous localities in these basins, but to the present time (1873) it has all been drawn in wagons from the mines to the Virginia and Tennessee railroad, a distance of from 2 to 8 m. The total amount mined cannot exceed 15,000 to 20,000 tons up to the year 1873. It has been used successfully in grates, stoves, cupola furnaces, puddling furnaces, and locomotives, but has not been tested in the blast furnace. Near the surface the coal is weak and friable, but at considerable depth it becomes more dense, solid, and pure. Much aluminous and carbonaceous shale exists in connection with this coal, and sometimes excludes it entirely, forming a "fault." The entire area of these two basins cannot exceed 10 sq. m. They are merely narrow synclinal belts, with an occasional repetition or fold forming two parallel basins, seldom more than 500 yards wide inclusively. The coal-bearing strata of this range or belt, however, are much more extensive than those embraced in the New river coal field, and extend over 200 m. N. E. and nearly 100 m. S. W. It is found in Sidelong hill, a continuation of Blue or North mountains in Pennsylvania, and exists in a basin of considerable extent on North mountain, a short distance W. of Martinsburg, West Va. In this locality there are two basins, one on the E. side of the mountain and another on the W. side, or rather on the summit of the mountain. That on the east is narrow and folded in the form of a V, the left or E. side inverted in the usual form of this range; but that on the summit is more regularly stratified, forming a comparatively shallow basin. Here we find all the indications of a true basin of the carboniferous era. The conglomerate and the red shale (Nos. XII. and XI. of the Pennsylvania geological survey) are in regular order and position, and the lower beds of coal are identical with A, B, and C of the Pennsylvania fields, in the order of stratification, character of bed, and color of ash. The area of this small upper basin is perhaps 5 sq. m. It lies on the head waters of Back creek, which flows into the Potomac W. of Martinsburg. Yet notwithstanding the greater regularity and order of these anthracite beds, they are faulty and

too small and impure to be mined for ordinary commercial purposes. The beds range from 3 to 5 ft. in thickness, of which two thirds may produce marketable coal. This range of coal-bearing strata may be traced with occasional gaps from this place to New river. The coal beds have been developed in a small way at the Dora mines on the North fork of the Shenandoah, W. of Staunton, where anthracite of good character has been mined for local use. The next point at which the coal has been mined is W. of Fincastle on Catawba creek. From here it has been dug into in many places to the Brush mountain basin on New river, and from New river it has been opened at many points to the Tennessee line; but the only localities yet developed, where this range contains beds in workable condition and productive of good coal for ordinary purposes, are those particularly described, including the Dora mines, which however are the most doubtful. This range of coal deposits has always been considered by geologists as belonging to the proto-carboniferous or false coal measures. Recent investigations have cast doubt on this classification, and those most familiar with the geology of the region are inclined to place it in the true coal measures as identical with the strata of the Pennsylvania coal fields.—Besides the principal anthracite fields already described, there are other small, partially developed, and less known deposits of anthracite in Arkansas, New Mexico, Sonora, and Oregon.—Of the remaining anthracite deposits of the world, those of France are most largely developed. The first and most extensive is a continuation of the Belgian coal field, in the department of Le Nord. The coal is of a dry or semi-anthracite character in a portion of the French extension, and about one half the coal products of this field is denominated anthracite in the French reports, but it is not strictly anthracite. The other French fields producing anthracite are named from the departments of Pas-de-Calais, Calvados, Sarthe, Maine-et-Loire, Loire-Inférieure, Corrèze, Puy-de-Dôme, Haute-Saône, Tarn, Haute-Loire, Ardèche, Isère, and Hautes-Alpes. The total annual production of coal in France is now (1873) over 10,000,000 tons, of which about 2,000,000 tons is anthracite and semi-anthracite, and of the latter more than one half is the product of the field of Le Nord. The European anthracite field next in importance to these is that of Donetz in S. Russia, between the Dnieper and Donetz rivers, which is perhaps the largest connected field containing anthracite yet developed. It embraces over 8,000 sq. m. of coal area, but, like the South Wales and Pennsylvania anthracite fields, one end contains anthracite and the other bituminous coal beds, according to Murchison; while anthracite and bituminous beds are found in the same locality, and the undulations of the strata, which dip from 20° to 70°, indicate a close resemblance to the peculiarities of the Pennsylvania anthracite fields. An analysis of

this anthracite gave 94.234 per cent. carbon. Anthracite also exists in Spain, Portugal, Germany, Austria, Norway, Persia, India, China, and South America; and generally anthracite is found in connection with the altered or metamorphic rocks, which accompany all great coal formations to a greater or less extent.—Anthracite undoubtedly owes its existence to a superior heat or a comparatively high temperature during its formation. The hardest and most dense anthracite is always found where the coal has been subject to a high temperature; but where the heat has been most intense, graphite rather than coal is found. In the New England field the outcrops of the coal beds frequently yield plumbago, which is collected and sold as "British lustre," and nests of pure graphite are found in the beds at considerable depth. An analogous condition is found in the pockets of carbonaceous coal which exist below A in the southern Pennsylvania field. The proportions of carbon are due to the varying degrees of heat to which the coal or the elements forming anthracite have been subjected. This fact is fully illustrated in the Pennsylvania anthracite beds, where the lowest contain the most carbon and the highest (in the measures) the most volatile matter. Where the coal is nearest to the igneous or plutonic rocks; whether granitic or metamorphic, whether in the deepest parts of the coal basins or on their edges, the conditions are the same, and all true coal fields are alike in these conditions. It is true, the Richmond (Va.) bituminous coal field is formed in the crater of an extinct volcano; but that field is a late creation of the Jurassic period, and was deposited when the earth and the rocks beneath it were comparatively cool, and even there a trap dike is intruded—evidently long after the completion of the coal field—between the beds. The effect of this heated and volcanic mass of rock has been to coke a coal bed 60 ft. beneath it, and burn one 10 ft. above it to a graphitic cinder. The general effect of trap intrusions seems to be the same in all cases, but the altered bituminous coal under such circumstances is rather a coke than an anthracite, which differs greatly in appearance, though the constituents are the same. Prof. H. D. Rogers explains the formation of anthracite by supposing it to be the result of altered bituminous coal metamorphosed by intense heat, and of course by heat induced subsequent to the formation of the bituminous beds; and he further explains the escape of the volatile portion of the latter as gas through cracks and openings caused by the plication of the anthracite strata. This plication follows closely the general type of the eastern palæozoic rocks, which are intensely crushed and folded near the contact of their edges with the igneous or granitic rocks, and much less plicated and distorted in a western direction. This fact undoubtedly led to the above theory, which seems as natural as it is ingenious; but the facts do not sustain the theory. 1st. The upper beds

and strata are more dislocated, distorted, and crushed than the lower beds, as plainly demonstrated by the plication of the strata on the apex of the leading anticlinals in the southern field. 2d. The measures are more plicated and crushed at the western extremity of this field, in the Dauphin or south prong, than at the eastern extremity; yet the coal of the latter is a dense, hard anthracite, while that of the former is semi-bituminous. 3d. The heat must have been most intense during the early stages of coal formation. In view of these facts, it has recently been contended that true anthracite is not a metamorphosis of bituminous coal, but as much a normal creation as the bituminous variety itself from a combination of its constituents under superior heat, however the original elements were produced. (See *COAL*.)—The faults and irregularities of the anthracite beds and strata are the result of crust movements, and the plication of the distorted and crushed rocks indicates contraction, both lateral and perpendicular, as the cause. The effects of a combined lateral and perpendicular movement are simply those which are evident in the plication of the anthracite beds of the southern Pennsylvania fields, and their accompanying shales; but the crust movements have been slow and uniform, bending rather than breaking the strata, except in cases of sharp foliation of anticlinals or synclinals. Where the folding has been most abrupt the strata are inverted, and the coal is crushed and partially destroyed. The coal beds thus distorted are always subject to faults of the peculiar character described in the New England and New river coal fields, as well as those of Pennsylvania. Such faults are more frequently met with in the upper than in the lower beds of the latter. A fault is rarely met with in the great white-ash beds B, D, and E, except where they are inverted or seriously dislocated by the plicating movements. The dislocations of American coal beds are rarely vertical, and never to any great extent, as in the English fields, where this form of fault is peculiar. The nearest approach to this in the former is a "slip" which may slide one portion of a bed over the other, or remove it a few feet up or down. In the anthracite fields, however, faults are much more numerous than in the bituminous fields of England or the United States, but these are generally of the characteristic form peculiar to highly plicated strata before described. There are, however, other less frequent forms of fault, such as the occurrence of large areas of soft carbonaceous shale in place of the coal; long ribbon-like streaks of rock or slate in the coal from the top of the bed, apparently to fill a crack in the same; or the interposition of rock and slate between the strata of a bed, dividing it so as to render valueless sometimes one or both divisions. These faults do not affect the accompanying beds. The preceding are such as are strictly denominated faults in the Pennsylvania anthracite fields; but the ever-varying

dip of the strata, the change of strike incident thereto, and the general irregularities of both coal bed and accompanying strata, would be denominated faults in the great bituminous fields of the United States or England.—The use of anthracite as a common fuel is recent. It was long supposed to be an inferior kind of coal, and the creation of an earlier period than the true carboniferous; even now there are a few professional men who adhere to this exploded theory. The first attempts to use it as fuel were as a substitute for wood or the free-burning bituminous coals, where a draught of air through the mass is not absolutely necessary, as in the case of anthracite. On account of this difficulty of ignition, and the prevailing ignorance in regard to the best methods of using it, anthracite was slow to be appreciated. In 1813 it was considered inferior in Wales, and was but little used for any purpose; and though known and tested as a valuable fuel in the United States arsenal at Carlisle, Pa., in 1776, and by smiths on the Susquehanna generally even at an earlier date, it was only in 1812 that it was successfully used in Philadelphia, and there the mode of burning it was discovered by accident. The general trade only commences with a few tons in 1820. (See table.) At first the increase of consumption was slow, but so soon as its use and advantages became generally understood, it assumed the first place in the list of combustibles. For household purposes it is preferred not only on account of its cleanliness and the absence of smoke and the peculiar odor of bitumen, but also on account of its durability and long continued and uniform heat. For war steamers, where the conspicuous smoke of bituminous coal is exceedingly objectionable during hostile movements, anthracite has been fully tested and found superior, not only because of the absence of smoke, but of its good steam-producing qualities, its duration at high temperatures, and the consequent maintenance of a steady uniform steam power. For the economical combustion of anthracite a strong draught rather than an abundant supply of air is required. In common use, however, where chimney draught is ordinarily employed, these two requirements are antagonistic, as far as economy is concerned. To obtain a draught strong enough to pass sufficient air through the coals, a high and hot chimney is required, which absorbs and carries off the largest proportion of calorific power from furnaces as commonly constructed. The coal is rarely burned to carbonic acid by direct combustion in this manner, but rather to carbonic oxide, which is lost, and more than half the fuel is thus wasted. The first or direct combustion, producing carbonic oxide, generates about 1300°C ., while the carbonic oxide is capable of producing over 2100°C . of heat in addition; but when anthracite is burned to carbonic acid direct in properly constructed gas-burning furnaces, the temperature is increased to 2400°C . The volume of heat or total heating effect is, however, in favor

of carbonic oxide as fuel, and it would be much more economical and generally useful to convert anthracite or bituminous coal to carbonic oxide before using it as a fuel. In the blast furnace, however, where anthracite is preëminent, the coal must be used in its solid condition; but here, in well constructed furnaces, the total heating effect of the coal is utilized. But it cannot be claimed that anthracite is a superior fuel for all purposes, because bituminous coal can be used in all cases, while anthracite cannot be used in the present state of the arts for the production of illuminating gas. Where a long hot flame is required, as in puddling furnaces, hydrogenous coal is more available; and for welding heats, where hollow fires are desirable, the latter class of coal is also used. But under proper combustion, anthracite, as the purest form of carbon available for fuel, will yield a higher temperature than any other kind of fuel.—The earliest record of the use of anthracite for the production of iron is in 1826, when a small furnace built under the direction of Messrs. White and Hazard of the Lehigh coal company, near Mauch Chunk, Pa., was tried with anthracite and cold blast; but, though several pigs of anthracite iron were made, the furnace chilled and the attempt proved a failure. Several other experiments were made both on the Lehigh and the Schuylkill, which were successful in the production of anthracite iron, but failed of practical results. Attempts had been made prior to this time to use anthracite for the production of iron in the blast furnaces of Wales; but nothing definite is given in regard to the date of these experiments until after the introduction of the hot blast by Neilson in 1831, or its more general use in 1833. Mr. David Thomas then conceived the idea of using anthracite with hot blast, and induced his employer to try the experiment. A coke furnace was accordingly altered during 1836, and provided with a hot-blast arrangement; and in February, 1837, anthracite iron was successfully made in Wales for the first time. In 1837 the Lehigh coal and navigation company, attracted by the success of the Welsh furnace, sent one of their directors to Wales, who engaged Mr. Thomas to start a furnace on the Lehigh, which was successfully accomplished in June, 1839. The "Pioneer Furnace" at Pottsville, built by William Lyman of Boston, had been put in blast a few months previous, after the directions of Mr. Thomas. For this Mr. Lyman was awarded a premium of \$5,000 which had been offered by Burd Patterson of Pottsville and Nicholas Biddle of Philadelphia for the profitable production of anthracite iron, and which was paid at a banquet given at Mt. Carbon early in 1840. Since then the Thomas and Crane iron works on the Lehigh have grown to mammoth establishments, and are now capable of producing 100,000 tons of pig iron per annum; and the total annual production of anthracite iron has now (1873) reached 875,000 tons.

ANTHROPOLOGY, the science of man. See ANATOMY, ARCHEOLOGY, COMPARATIVE ANATOMY, ETHNOLOGY, MORAL PHILOSOPHY, PHILOSOPHY, AND PHYSIOLOGY.

ANTHROPOMORPHITES (Gr. *άνθρωπος*, man, and *μορφή*, form), those who believe that God possesses a human shape. Audius, a Syrian layman (340), taught that God essentially exists in human form, and opposed the authority of the clergy. He was excommunicated, and his sect disappeared after about a century. In the 10th century anthropomorphism was revived, but did not attain any prominence as a doctrine.

ANTIBES (anc. *Antipolis*), a town and seaport of France, department of Alpes-Maritimes, built on a promontory jutting into the Mediterranean, 15 m. S. W. of Nice; pop. in 1866, 6,829. It has fortifications erected by Vauban and some Roman antiquities, including an aqueduct in good preservation. The chief industry and trade are in salted fish, dried fruits, wine, and olive oil. The town was founded by the Greeks of Massilia (Marseilles) in the 4th century B. C. Under the Romans it was a military station and an important seat of commerce, but it was ruined by the barbarians and Saracens. In later times it was strongly fortified, and successfully withstood a siege of the English and Imperialists in 1746.

ANTICHLOR, in chemistry, any substance capable of eliminating the excess of chlorine or of free hypochlorous acid left in goods and paper after the process of bleaching by chloride of lime. Several agents can be employed, and they generally act by converting the chlorine into an innocuous salt. *One of the first substances employed for this purpose was the sulphite and bisulphite of soda patented by Henry Donkin in 1847. In 1853 these salts were superseded by the hyposulphite of soda, which has now become the principal antichlor of commerce. Sulphide of calcium, prepared by boiling sulphur with milk of lime, has also been used as an antichlor; so likewise has a solution of protochloride of tin in hydrochloric acid. In the latter case, however, it is necessary, after the completion of the bleaching process, to add carbonate of sodium, in order to neutralize the free hydrochloric acid, which would otherwise act as injuriously as the free chlorine itself. The precipitate of oxide of tin thereby produced is quite white and soft, and does not interfere with the subsequent stages of the paper manufacture. Coal gas was also used as an antichlor in paper making as early as 1818, but it is not so convenient as the agents mentioned above. The products formed by the action of chlorine (or hypochlorous acid) on sulphite or hyposulphite of sodium are sulphate and chloride of sodium, both of which are innocuous and easily removed by washing.

ANTICHRIST (Gr. *άντι*, against, or in place of, and *Χριστός*, Christ), a term which occurs five times in the Bible, but only in the first and second epistles of John. These passages recognize the previous teaching that "Antichrist

shall come;" declare the existence even then of "many Antichrists," who "went out from" the Christians, but "were not of" them; and characterize as an Antichrist him "that denieth the Father and the Son," or "confesseth not that Jesus Christ is come in the flesh." Most interpreters identify Antichrist with the "man of sin" (2 Thess. ii. 3); many also with the "little horn" of Daniel's fourth beast and the "king of fierce countenance," with the Apocalyptic beast and false prophet, and with the false Christs and false prophets foretold in Matt. xxiv. 5, 11; but all these are controverted points. The numerous representations of Antichrist given by Biblical critics and theologians may be arranged under the following five heads: 1. An individual yet future. Thus most of the early Christian fathers represent the "many Antichrists" of the apostle's day as forerunners or types of a terrible future Antichrist—a person (of the tribe of Dan, according to Aretas, Bede, &c.) armed with Satanic powers (Satan himself, say some)—who is to come just before the final and glorious appearance of Christ, and then to be destroyed by Christ. 2. A polity or system. Thus the Waldenses, Wycliffites, reformers of the 16th century, and others, make Antichrist to be the papal system, or the pope as representing the Roman Catholic polity; others, imperial or pagan Rome; others, Mohammedanism, or popery and Mohammedanism, or Judaism and pagan Rome and papal Rome, &c. 3. An individual already past. Thus Antichrist has been found by different Roman Catholic and Protestant expositors in one or another heathen emperor of Rome, Jewish leader, false Messiah, or heresiarch. 4. A class united in opposition to Christ. This opinion, held by Bengel, MacKnight, Bishop Wordsworth, &c., makes Antichrist a collective term, equivalent to the "many Antichrists" of 1 John ii. 18, or the embodiment or representative of a limited or unlimited class of those who set themselves up against Christ, as the false prophets or teachers about the time of the destruction of Jerusalem, or all false teachers in every age, or the particular class who deny that Jesus is the Christ, or all heretics, &c. 5. An evil principle personified. This opinion, held by Koppe, Nitzsch, and others, is naturally connected with the view that Satan is not a person, but only evil personified.—It may be added that Jewish rabbinical books describe Antichrist under the name of Armillus, who, it is said, will defeat and slay the Messiah Ben Joseph, but will himself be defeated and slain by Messiah Ben David; and that Mohammedan traditions represent the Jewish Messiah Ben David as himself Al-Dajjal (Antichrist), who will be slain by Jesus.

ANTICOSTI, an uncultivated island in the gulf of St. Lawrence, 120 m. long and 30 m. wide in the centre, narrowing toward both ends. It divides the gulf into a N. and a S. channel. The E. point is in lat. 49° 5' N., lon. 62° W.; the

W. point in lat. 49° 48', lon. 64° 35'. Along a great part of the coast there is a dangerous belt of reefs uncovered at low tide. There are two harbors comparatively safe at all times: one at Gramache or Ellice bay, near the W. end, and the other at Fox bay on the northwest. The coast line on the S. side rises from 20 to 30 feet above the water; on the N. a succession of ridge-like elevations, separated by depressions, rise from 200 to 500 feet. On the S. side there are excellent peat beds 80 m. in length and 2 in width, with a depth of from 3 to 10 feet, and marl beds of considerable thickness. There are three lighthouses on the island.

ANTICYRA. I. An ancient city of southern Thessaly, on the Spercheus, famous for producing the best hellebore, which was regarded by the ancients as a cure for madness. II. A city of Phocis on the Corinthian gulf, also celebrated for the production of hellebore. The Anticyraeans are said to have been expelled from their city by Philip of Macedon after the close of the sacred war. It was taken in a subsequent age by the Roman general Laevinus, and given up by him to the Ætoliens. It was occupied during the Macedonian war by the consul Flaminius, for the sake of its harbor, which afforded a secure retreat for the Roman fleet. The site of Anticyra is still discernible on the shore of the Corinthian gulf, and known as *Aspra Spitia*, or "the white houses."

ANTIDOTES (Gr. *ἀντί*, against, and *δίδοναι*, to give), a term formerly used to signify remedies or preservatives against sickness, but now applied only to means for counteracting the effect of poisons. To get rid of once of the poisoning substance, to hinder its absorption, or to counteract its effects, are the general results to be sought for. The first of these objects is attained, when the poison is in the stomach, either by the stomach pump or an emetic. If a stomach pump is not at hand, an ordinary elastic syringe with a stomach tube may be made to do duty in washing and pumping out the stomach. The best emetics are those which act rapidly, especially mustard, which is almost always at hand, sulphate of copper (blue vitriol), or sulphate of zinc (white vitriol), the vomiting being encouraged and kept up by tickling the fauces, giving large draughts of warm water, &c. If the poison has been thrown into or under the skin, as by the bites of serpents or mad dogs, or wounds from poisoned weapons, it may be sneked out by the mouth or a cupping glass; the wounded part may be excised, or a ligature placed so as to hinder the entrance of the poison into the system. Dr. Fayrer's elaborate experiments have shown that these procedures, to be of any avail, must be put in force with the utmost promptness, since only a few seconds suffice for the poison of venomous serpents to enter the circulation. The cauterization of such wounds either with the hot iron or powerful chemical agents, such as nitric acid, nitrate of silver, and ammonia, has been practised.—

Many substances may be rendered insoluble or comparatively inert in the stomach by appropriate chemical reagents. Strong acids may be neutralized by magnesia, chalk, or soap; caustic alkalies by vinegar. We may use for arsenic freshly precipitated sesquioxide of iron, which every druggist should have the materials at hand for preparing at short notice. That which has been kept under water, or the so-called subcarbonate, may be used in case the first is not ready. The light magnesia, or freshly precipitated gelatinous magnesia, has also been used. A mixture of chalk and castor oil, of the consistence of cream, is said to envelop the particles of arsenic still adherent to the stomach after it has been washed, and render them harmless. For bichloride of mercury, albumen (eggs), gluten (wheat flour), or caseine (milk) may be used, but should at once be followed by an emetic, as the precipitate formed is not absolutely insoluble. With lead and baryta, sulphates form insoluble precipitates; with sulphate of copper or zinc carbonate of soda, and with oxalic acid carbonate of lime (chalk) may be used. The vegetable astringents (galls, tannic acid, strong tea), and also a solution of iodine in iodide of potassium, form insoluble precipitates with some of the alkaloids.—The antidotes which fulfil the third indication, counteracting the effects of poisons, are not so well determined. Inflammation from irritant poisons is to be treated on general principles. Opium narcotism is to be treated by external irritants, such as cold affusion or forced exercise and strong coffee. The efficacy of belladonna as an antidote to opium, and *vice versa*, is not established. For prussic acid ammonia may be cautiously used. The symptoms of nuxvomica and strychnia may be partially controlled by chloroform, elioral (if there is time for it to act), or bromide of potassium. Aconite has been proposed. Aconite poisoning calls for stimuli, as alcohol and ammonia.

ANTIETAM, Battle of, fought by the national army of the Potomac, under Gen. George B. McClellan, and the confederate army of North Virginia, under Gen. Robert E. Lee, between Sharpsburg and the Antietam creek, an affluent of the Potomac river, Sept. 16 and 17, 1862. After the defeat of the army of the Potomac in the seven days' fighting on the line of the Chickahominy, the confederates prepared for an invasion of Maryland, worsted Pope's army at Cedar Mountain, in the second battle of Bull Run, and at Chantilly, crossed the Potomac near Leesburg, and concentrated their forces at Frederick. Meanwhile the national army had been withdrawn from Harrison's Landing and consolidated at Washington with Pope's command, and the whole, under McClellan, moved out to meet Lee. The right wing, consisting of the 1st and 9th corps, was under Burnside; the centre, composed of the 2d and 12th corps, was under Sumner; and the left wing, composed of the 6th corps, was under Franklin. In this order McClellan marched

by the Rockville turnpike, the right wing of his army extending toward the Baltimore and Ohio railroad, and the left toward the Potomac. His advanced guard entered Frederick as the confederate rear guard was leaving it. At this place, on Sept. 12, he became acquainted with the disposition of Lee's forces, as well as with his immediate plans, through a copy of Lee's marching orders which one of the confederate commanders had inadvertently left behind him. Lee, having captured all the outlying detachments of the national army, including that in the stronghold of Harper's Ferry, and thus secured his communication with Richmond, concentrated all his available forces, choosing his position in front of Sharpsburg, in the angle between the Potomac, which covered his rear, and the Antietam, whose deep bed and precipitous sides covered his front. Lee's line, forming almost a semicircle about the village, covered all the roads concentrating at that place; its right wing rested on the heights dominating the creek, and stretched along it, sweeping all the crossings for more than half a mile; the centre occupied the open fields and patches of wood extending to the Hagerstown road, and the left rested upon the Potomac. McClellan's army approached the battlefield along the turnpike leading from Keedysville to Sharpsburg, his main body going into position on the left bank of the Antietam on the afternoon of Sept. 15. No fighting took place on this day. The greater part of the 16th was passed in harmless cannonading, but late in the afternoon McClellan threw forward Hooker's corps, with orders to force a passage of the Antietam by the upper one of the four stone bridges spanning the creek in that neighborhood. This bridge, being beyond the reach of the confederate line, had been left undefended, and Hooker's crossing was therefore quickly and easily made. Pushing forward at once through a narrow piece of woods, he soon struck the confederate left under Hood, and after a sharp skirmish, terminating with nightfall, in his favor, his corps rested on their arms near the Hagerstown road, almost in contact with the enemy's line. This advance served to place one corps of 18,000 men in a good position to give battle as well as to uncover the other crossings of the Antietam as far down as the Keedysville road, thus rendering it easy for McClellan to secure his initiatory movement, by sending Mansfield's 12th corps, under cover of darkness, to strengthen Hooker. On the morning of the 17th the disposition of the combatants was as follows: Lee's position was substantially unchanged; his entire army, estimated at about 65,000 strong, was formed in a semicircular line covering the roads converging at Sharpsburg. Hooker's and Mansfield's corps of McClellan's army had crossed the Antietam and held advanced positions on the extreme right; Sumner's corps held itself in readiness to cross; Porter's corps was in reserve, cover-

ing the Keedysville bridge, but separated from the enemy by the creek; and Burnside's corps occupied the extreme left, and was also separated from the confederate position by the Antietam. The aggregate strength of these corps was about 85,000 men; but being partly on one side and partly on the other side of a stream which could hardly be crossed anywhere except by a bridge, and which was particularly easy to defend, the superior strength of the Union army counted but for little in the bloody conflict which followed. McClellan's plan was for Hooker and Mansfield, supported by Sumner, to attack the confederate line, and engage it so closely as to permit Burnside, advancing simultaneously, to force a passage at the lower bridge, and thus unite all the corps except the reserve on the further side of the Antietam, with their entire strength available for the final struggle. Hooker's corps held a position close to the enemy's line, and was therefore forced to begin skirmishing almost as soon as it was light. After gaining some slight advantages it attacked with great fury, and succeeded in forcing Lee's left under Jackson backward for nearly half a mile before it received the slightest check. Hooker gave his men a short breathing spell, and dashed forward again; but his divisions were already fatigued as well as greatly shattered by their bloody work. Meeting the reserves of the enemy's left, they were in turn driven back to the position from which they advanced less than an hour before, notwithstanding Mansfield had in the mean time hastened forward to join in the conflict. This gallant veteran lost his life in trying to regain the ground lost by Hooker, and, although aided by a terrible fire from the reserve artillery of the Union army, stationed near the Keedysville bridge, his corps was also forced to retire to the position from which it had advanced. McClellan now ordered Sumner to advance, and this resolute commander accordingly made his appearance on the battlefield about 9 o'clock, and with all the precision of a parade moved his corps of four divisions against the confederate line, over a part of the field somewhat to the left of that covered by Hooker and Mansfield, but directed mainly against the woods to the west of the Dunker church on the Hagerstown road. The confederates, having had time to rectify and strengthen their lines, received this formidable attack with steadiness; but so fierce was the onset of Sumner's right division under Sedgwick, that the confederate division confronting him was driven back into and beyond the woods, when it was strongly reinforced by troops which had arrived upon the field only that morning. The confederates now made a spirited counter attack, directing their movement mainly against Sedgwick, who was in echelon with the other divisions of Sumner's corps, and therefore poorly supported by them. The fighting which ensued was characterized

by the greatest bravery, but when it ceased Sumner's entire corps was also defeated, and the enemy's line completely restored. By 11 o'clock half of the Union army and nearly all of the confederate army had been engaged. The latter, standing in a close and compact line, on its own chosen ground, had been able to act as a unit, while the former at the outstart was divided by the Antietam, and had spent its force in gallant but disconnected attacks, resulting in defeat by detail, accompanied by an immense loss of life. Had Lee known at any time during the afternoon the extent of the injury he had inflicted upon the right wing of the Union army, and assumed the offensive, it is scarcely to be doubted that he would have gained a complete victory notwithstanding the timely arrival of Franklin's corps on that part of the field. Neither Burnside's nor Porter's corps had yet been seriously engaged, although the former had been ordered to attack simultaneously with the other corps. His failure to carry the bridge in his front and to effect a lodgment beyond was due to the fact that it was swept by the sharpshooters of the enemy's right, occupying the commanding hillocks close to the borders of the creek. The confederate position here was very strong, and, being covered by the Antietam, almost entirely impassable in this portion of its course, was practically unassailable. Burnside advanced promptly as ordered, but his foremost troops encountered such a galling fire that they could not even reach the bridge, much less carry it. After several hours' delay Burnside succeeded in throwing one brigade across the creek by a ford which had been discovered some distance below, thus relieving the pressure in his front, and permitting the main body of his corps to cross by the bridge and to secure a good position on the right bank of the creek. After reforming his lines Burnside advanced, carried the heights beyond, and pressed back the enemy's right several hundred yards; but his attack not being supported by detachments from the other parts of the army, as it should have been, he was defeated and driven back almost to the creek, as the other corps had been. Night ended the conflict with both armies concentrated and confronting each other on the W. side of the Antietam. On the 18th McClellan stood on the defensive. During the day he received the reinforcement of two strong divisions under Humphreys and Couch, and then resolved to attack the next day; but meantime Lee had made good his retreat to the south side of the Potomac. McClellan's loss in this action was 2,010 killed, 9,416 wounded, and 1,043 missing; total, 12,469. Lee's army, having fought on the defensive throughout, and frequently under cover, is estimated by confederate writers to have lost only about 9,000. This battle was followed rather by negative than positive military results. The confederate army retired to Virginia and assumed a defensive attitude; the

people of Maryland did not rise in rebellion, and the national capital did not fall into the hands of the invaders. On the other hand, the political measure which followed it was positive and far-reaching in its effects. President Lincoln had made a solemn vow that if Gen. Lee was driven back from Maryland, he would crown the result by issuing a proclamation abolishing slavery, which was done, at least conditionally, on the 22d day of September, 1862.

ANTIGONE, one of the tragic characters in the Greek legends, a daughter of Œdipus by his mother Jocasta. When Œdipus, after discovering that he had killed his father and married his mother, put out his eyes in despair and went to Attica, Antigone guided him on the way and attended on him till his death. She then returned to Thebes, where Hæmon, son of the tyrant Creon, became enamored of her. The brothers of Antigone, Polynices and Eteocles, having fallen in the war for the possession of Thebes, and she having attempted to bury Polynices in defiance of an edict of Creon, the tyrant ordered her to be buried alive or to be shut up in a cave, and Hæmon slew himself by her side. The story of Antigone was a favorite subject with the great tragic poets of Greece, and is told with some variations.

ANTIGONUS. **I**. The Cyclops (so called from having lost an eye in battle), a Macedonian officer of Alexander the Great, and subsequently king of Asia, slain at the battle of Ipsus in Phrygia in 301 B. C. At the distribution of Alexander's empire, Antigonus received as his share the greater Phrygia, Lycia, and Pamphylia. Attacked by Perdiccas, he took refuge at the court of Antipater, regent of Macedonia and Greece. On the death of Perdiccas in Egypt (321), Antipater made a new distribution of the Asiatic provinces. Antigonus had Susiana added to his former dominions, and to him was committed the charge of annihilating Eumenes, the ally of Perdiccas. By bribing one of his officers, Antigonus gained a victory over Eumenes and shut him up in the fortress of Nora in Cappadocia. In the mean time Antipater died (319), and Antigonus in his turn began to aspire to that universal dominion at which Perdiccas had aimed. First destroying Eumenes (316), he occupied Susa, the Persian capital, and wrested Babylonia from Seleucus. A coalition was now formed against him by Seleucus, Ptolemy of Egypt, Lysimachus of Thrace, and Cassander, the son of Antipater; but Antigonus, with the aid of Aristodemus of Miletus, succeeded in combining many of the Hellenic cities in his support, and, though Seleucus recovered Babylonia, the Macedonian garrisons were expelled from the Peloponnese, Eubœa, Thebes, and the greater part of Phocis and Locris. After a truce of one year, during which Cassander murdered Roxana and the young Alexander (311), the war broke out again. The restored Athenian democracy paid

to Antigonos and his son Demetrius Poliorettes extravagant honors. Having defeated Ptolemy in a sea fight off Salamis in Cyprus (306), Antigonos threw off the pretence hitherto kept up by the generals of Alexander that they were holding merely for his heirs, and assumed the title of king. Ptolemy, Lysimachus, and Seleucus immediately called themselves kings also. Cassander, general of Macedonia, held back a little longer, but soon followed. Cassander, driven out of Greece by Demetrius (303), now formed a league against Antigonos with Seleucus and Ptolemy. In August, 301, the armies met at Ipsus. Antigonos and his son had upward of 70,000 foot, 10,000 horse, and 75 elephants; the coalition had 64,000 foot, 10,500 horse, 400 elephants, and 120 armed chariots. Demetrius defeated Antiochus, the son of Seleucus, but pressed him too far in pursuit, so that Seleucus cut him off. The Thracian archers of Lysimachus broke the centre, where Antigonos, now at the age of 81, was commanding. He would not flee, saying Demetrius would come and help him, and died on the field of battle, leaving the victory to those who represented the principle of a balance of power in the world. **II. Antigonos Gonatas**, king of Macedonia, grandson of the preceding, and son of Demetrius Poliorettes, born in 319 B. C., died about 240. He is supposed to have received his surname from his native village of Gona or Gonni in Thessaly. When his father was captive in the hands of Seleucus, king of Babylon, Gonatas offered to take his place. The affairs of Macedonia having fallen into confusion after the invasion of the Gauls, Ptolemy Ceraunus having been slain by them, and Sosthenes having died, Antigonos entered Macedonia with a small force, drove out the Gauls, and was accepted by the Macedonians as their king, 277 B. C. But Pyrrhus, king of Epirus, expelled him in 273, and he fled to the Peloponnesus. On the death of Pyrrhus shortly afterward he recovered Macedonia, was again expelled by Alexander, son of Pyrrhus, and again reinstated by his own son Demetrius. Nearly all that is known of his subsequent reign is his attempt to prevent the formation of the Achæan league. He was succeeded by his son Demetrius II. **III. Antigonos Doson**, king of Macedonia, born in 280 B. C., died in 220. His surname was given him to signify that he was always promising gifts which he never gave. He was an illegitimate grandson of Demetrius Poliorettes, and in 229 was named guardian of Philip, the young son of Demetrius II., whose widow he married. The Macedonian nation preferred his rule on account of his military talents, and chose him to be their king. He was successful in his wars for the suppression of the Dardanian, Thessalian, and Mæonian revolts. In the affairs of the Peloponnesus he took the part of Aratus and the Achæan league against Cleomenes and the Spartans. He defeated Cleomenes decisively at Sellasia in 221,

and took the city of Sparta, but was recalled by a revolt of the Illyrians, whom he defeated. He was succeeded by his ward Philip V. **IV.** King of the Jews, and the last of the Asmoneans, born in 80 B. C., died in 35. He was the son of Aristobulus II., and was made prisoner and sent to Rome by Pompey. He escaped, headed a revolt in Judea, and was taken a second time by Gabinus, who sent him again to Rome. Julius Cæsar permitted him to return. He was placed on the throne of Judea by the Parthians in 40 B. C., and was besieged in Jerusalem by Herod and Sosius, a lieutenant of Mark Antony. He was taken, sent to Antony, scourged, and put to death.

ANTIGUA, one of the British West India islands, in the Leeward group, 40 m. N. of Guadeloupe, about 18 m. in diameter; area, 108 sq. m.; pop. in 1871, with the adjacent island of Barbuda, 35,157, including 2,146 whites. It is the residence of the governor of the Confederation of the Leeward Islands, who is also governor of Antigua. There are no rivers, and the coasts are generally dangerous to shipping; but there are three good harbors: St. John's, the capital, on the W. side; English Harbor, on the S., where there is a large dockyard and a royal mail packet station; and Parham on the N. The revenue in 1869 amounted to £38,586, the expenditure to £39,252, and the public debt to £54,431. The chief products consisted in 1866 of 17,330 hogs-heads of sugar, 7,852 puncheons of molasses, and 696 of rum; and the total tonnage of vessels entered and cleared, exclusive of coasting trade, was 43,906. The total exports in 1869 were £200,973, and the imports £174,357.—Antigua was discovered by Columbus in 1493. A few English settled there in 1632. In 1666 a grant of it was made by Charles II. to Lord Willoughby. After an interval of French occupation, which laid waste the island, it was again settled by Col. Codrington and formally ceded to Great Britain (1667). The legislature liberated the slaves, numbering about 30,000, unconditionally in 1834. The sum awarded for their emancipation was nearly £426,000, including those of Anguilla. The island contains besides the capital five towns, and about 100 villages of emancipated slaves. Antigua is one of the Confederation of the Leeward Islands. This Confederation commenced in May, 1872, Sir Benjamin C. C. Pine being governor.

ANTI-LIBANUS, or *Anti-Lebanon*, a mountain ridge of Palestine, one of the two offsets of the Taurus which are thrown off from that range as it passes the N. E. point of the Mediterranean and take a southern direction parallel to each other, as well as to the coast. The western and highest of these ranges, or in a narrower sense its main portion, is the Libanus or Lebanon; the eastern is the Anti-Libanus, called by the natives *Jebel esh-Shurki*. In the central part of their course they are separated by the valley of Cæle-Syria, 20 m. in breadth. To the south the Anti-Libanus sends off a spur

which unites with the Libanus, and so separates the interlying valley into the northern or Syrian, and the southern or valley of Jordan. Through the northern flows the Orontes or Aasy. In the heights of Hermon, the uniting spur, and the highest land of the Anti-Libanus range (9,000 feet), rises the Jordan, which flows to the south; between it and the Orontes rises the Leontes or Litany, which, coursing to the S. W., enters the Mediterranean. The Anti-Libanus range is lower than the Libanus, and less continuous. Geologically it is less fossiliferous, as its limestones approach a crystalline character, giving more striking evidences of volcanic agency. It lacks also the far-famed cedars of Lebanon, its foliage being mostly of white poplar. It abounds in small lakes enclosed in its small table lands, a characteristic mostly wanting to the Libanus range.

ANTILLES, a name of somewhat loose application, but generally given to two groups of the West India islands. The name of Antilla is sometimes supposed to have been applied by Columbus to his first discoveries in the new world, because a continent of that name had previously been believed to exist W. of the Azores. Others derive the word from *ante islas* (forward islands), and apply it to the Caribbean group. At the present day geographers generally distinguish Cuba, Hayti, Porto Rico, Jamaica, and the small neighboring islands of Caymanbrack, Great and Little Cayman, and Isla de Pinos as the Greater Antilles; and the Windward group or Caribbeans, extending in a semicircular line from Porto Rico to the mouth of the Orinoco, as the Lesser Antilles. (See WEST INDIES.)

ANTI-MASONRY, a political movement which originated in the state of New York in 1827. In the autumn of 1826 William Morgan, a mechanic of Batavia, N. Y., who was reported to be about to publish a volume exposing the secrets of the order of freemasons, of which he had been a member, was kidnapped and carried off. Committees of vigilance and safety were formed, and an investigation initiated, which resulted in tracing the abductors and their victim westward to Fort Niagara, near Lewiston, N. Y., whence it appeared that Morgan had been taken out upon Lake Ontario in a boat and drowned. This was the final conclusion of those who prosecuted the investigation, though reports were repeatedly current that Morgan had been seen alive and at liberty months after his reported abduction. One of these accounts placed him in Smyrna in Asia. The persons by whose aid he was rapidly and quietly conveyed, in a carriage drawn by relays of horses, from Batavia to Fort Niagara, were said to have been freemasons. Prosecutions were in due time instituted against those whom the investigation showed to have been in any way concerned in the abduction, and repeated trials resulted in the conviction of some of them on minor charges, but no murder was ever judicially established. It was supposed to be shown

in the course of these trials that the masonic oath disqualified masons in certain of the higher degrees for serving as jurors in any case where a brother mason of like degree was a party, and his antagonist was not. The anti-masonic party was thereupon formed in western New York, and polled 33,000 votes for its candidate for governor, Solomon Southwick, in 1828. This vote rose to 70,000 in 1829, and to 128,000 for Francis Granger for governor in 1830; in which aggregate, however, were included the suffrages of many who were not anti-masons. The excitement gradually diffused itself into other states, and in 1831 a national anti-masonic convention was held, wherein most of the free states were represented, and William Wirt of Maryland was nominated by it for president of the United States, with Amos Ellmaker of Pennsylvania for vice president. Mr. Granger was again the anti-masonic candidate for governor of New York in 1832, and received the votes of nearly all opposed to the reelection of Gen. Jackson, but was defeated by about 12,000 majority. In Pennsylvania Joseph Ritner was this year brought forward as the anti-masonic candidate for governor, and beaten by barely 3,000 votes by Gov. Wolf, who had many enemies in his own party; but at the presidential election in the same year, Gen. Jackson carried the state over the combined opposition by 25,000 majority. Anti-masonic state and electoral tickets were supported in many if not most of the free states, but were successful only in Vermont, which cast her seven electoral votes for Wirt and Ellmaker. Vermont remained for two or three years under anti-masonic rule, but the party gradually faded out, and was absorbed by others during the political and financial struggle that grew out of Gen. Jackson's veto of the United States bank charter in 1832, and the removal of the deposits in 1833. Until then western New York, the theatre of the Morgan abduction and the cradle of the anti-masonic excitement, gave large anti-masonic majorities; while western Pennsylvania, northern Ohio, and portions of Massachusetts and Rhode Island, evinced a preponderating sympathy therewith. In 1835, during the struggle which followed the removal of the deposits, Joseph Ritner was chosen governor of Pennsylvania as an anti-mason, through a division in the democratic ranks; but the anti-masonic party gradually lost its distinctive character, and soon after ceased to exist.

ANTIMONY, a metal first extracted from the ore in 1490 by Basil Valentine, a monk of Erfurt. It is of a silver-white color, slightly bluish, of strong lustre, and of a peculiar taste and smell. Its texture is radiated and fibrous, and the metal is so brittle that it may be pounded to powder in a mortar. For this reason it cannot be used alone for any practical purpose, but combined with other metals it forms valuable alloys. Its specific gravity is 6.7, its melting point 842° F. At common temperature it does not oxidize, but heated moderately in the

open air, it takes fire and burns with a bright bluish-white flame. The vapor is an oxide, which in condensing often forms beautiful crystals, formerly known as the argentine flowers of antimony. The metal also, after being melted in close crucibles and cooled very slowly, crystallizes in octahedral forms. The name is said to be derived from *anti-monachos*, or antimons, some preparation of the metal having proved fatal to several of the brotherhood, notwithstanding it had been observed that the same mixture had a fattening effect upon hogs, after purging them. A more probable derivation is from *atimad*, its Arabic name. The ancients gave the name *stibium* to some compound of the ore they were acquainted with, which was without doubt the common ore of commerce, the sulphuret. This name is adopted in chemical nomenclature to represent the metal. Its symbol is Sb. Antimony is sometimes found in a metallic state. It so occurs in the Hartz, in France, and in Sweden. The only important natural production of it, however, is the sulphuret, a combination of 71.77 per cent. of the metal and 28.23 of sulphur. This ore is of a lead-gray color, crystallized in laminae and needles, which are very brittle and fusible in the flame of a candle. Its specific gravity is from 4.13 to 4.6; hardness=2. It is easily ground to a black powder, and in this state forms a pigment, which appears to have been used in ancient times by ladies for coloring the eyebrows and edges of the eyelids. The ore is not of rare occurrence in metalliferous districts; but the great supply of it is from the island of Borneo, through Singapore. There are mines of it in lower Hungary, France, and Great Britain. A large vein has been found in Tularé county, California, about 80 miles from Los Angeles, in a high granitic range that borders the Tularé valley on the south. Its separation from the sulphuret is now effected by first melting the ore in crucibles, perforated at the bottom, and placed in other vessels. As the ore melts, it flows through into the lower vessel, unaltered in composition, but freed from its earthy gangues. This is the crude antimony of commerce. On roasting it to expel the sulphur, different combinations of oxide of antimony and sulphur are formed—as the glass of antimony, the liver of antimony, and crocus. The first-named consists of 8 parts of oxide and 1 of sulphuret. It is a transparent salt, of a reddish yellow color. Crocus contains 2 parts of sulphuret to 8 of the oxide; it is opaque and of yellow-red color. Liver of antimony is opaque and deep brown; it consists of about 4 parts of sulphuret and 8 of oxide.—Crude antimony is reduced to a metallic state by first carefully roasting it to obtain the oxide. This is then mixed with crude tartar, or with carbonate of soda, and powdered charcoal, placed in melting pots, and heated in a wind furnace. An impure metal is thus obtained, called the regulus of antimony. This is again melted with a small proportion of oxide of antimony, by

which it is freed from its impurities. Antimony combines with oxygen in three proportions, the first forming the peroxide, Sb_2O_3 ; the third quinquioxide, or antimonic acid; and the second antimoniate of antimony, or quadroxide, a compound of the other two.—The most important alloys of antimony are: type metal, consisting of 4 parts lead and 1 of antimony, which when used for stereotyping has added to it $\frac{1}{8}$ to $\frac{3}{5}$ of tin; Britannia metal, 100 parts tin, 8 antimony, 2 bismuth, 2 copper; and various white alloys used for teapots, spoons, and forks. Pewter may be made of 12 parts tin, 1 part antimony, and a little copper.—Several compounds of antimony are used in medicine. The *pulvis antimonialis*, corresponding to the nostrum James's powder, is composed of 1 part teroxide of antimony and 2 parts precipitated phosphate of lime. Kermes mineral is a compound of teroxide and tersulphide in varying proportion, and the precipitated sulphide contains also a portion of teroxide. The most important preparation is the tartrate of antimony and potassa, or tartar emetic. This drug causes vomiting by a specific effect upon the nervous centres. It has a peculiar depressing effect upon the heart and muscular system, both when it produces vomiting and when tolerance, as it is called, has been established. In poisonous doses it produces burning in the mouth, throat, and stomach, hiccough, copious secretion of mucus and saliva, colic and diarrhoea, muscular weakness, sometimes convulsions and cramp, and a pulse at first weak and slow, then weak and rapid. In chronic poisoning the symptoms are similar, but less marked. Frequently repeated, with intervals of comparative ease, they lead to emaciation, loss of strength, and finally fatal depression. The post-mortem appearances are not very characteristic, and for medico-legal purposes the presence of the drug must be demonstrated.—There are various processes for extracting antimony from suspected matter, which consist essentially in oxidizing and dissolving it in acids. Its presence may be demonstrated by the formation of characteristic precipitates, or by its deposit in a metallic form by Marsh's or Reinsch's test. The metallic spot formed by antimony in Marsh's test is less volatile than that of arsenic, and is insoluble in hot nitric acid or hypochlorite of soda, both of which dissolve arsenic. Tartar emetic is much less used in medicine than formerly, but still finds some favor as a diaphoretic and expectorant, and as a cardiac sedative in inflammatory diseases, especially pneumonia. Statistics, however, do not speak in its favor as compared with less depressing agents. In most cases other substances possess advantages over this drug as an emetic. Externally, in the form of ointment, it produces a pustular eruption. In poisoning by tartar emetic, vomiting should be encouraged by tickling the fauces and drinking warm water, or the stomach pump may be used. Tannin, such as exists in galls or in green tea,

renders less active any of the drug which may remain in the stomach. Subsequent inflammation is to be treated on general principles.

ANTINOMIANS (Gr. *ἀντί*, against, and *νόμος*, law), those who reject the moral law as not binding upon Christians. Some go further and affirm that a child of God cannot sin; that the moral law is abrogated as a rule of life; and that good works hinder salvation. Wesley defines antinomianism to be "the doctrine which makes void the law through faith." Antinomianism in a modified form early showed itself in the Christian church, as appears by the Epistle of James, and later in the writings of Augustine, by whom it was opposed. Its full development is due to John Agricola (1492–1566), one of the early coadjutors of Luther. He maintained that the moral law was superseded by the gospel; that the law is binding only upon unbelievers, but as soon as a man exercises faith in Christ, he comes under a new moral economy with which the law has no possible relations; that the law is not in any way instrumental in bringing men to the benefits of the new dispensation, but that faith and repentance are to be secured only by the preaching of the gospel. He affirmed that these conclusions followed as necessary consequences from the doctrines taught by Luther, and that he and Melancthon were inconsistent in not admitting them. The controversy between Luther and Agricola became violent. It was partially reconciled at a conference at Torgau (1527), when after a sharp debate Agricola retracted his doctrines; but, according to Melancthon, "he was not convinced, but overborne." In 1537 Agricola, being then established at Wittenberg, put forth anonymously a series of theses on the nature of repentance and its relations to faith, in which his former views were more strongly expressed: "Art thou steeped in sin, an adulterer or a thief, if thou believest, thou art in salvation. All who follow Moses must go to the devil; to the gallows with Moses." Luther replied in a series of disputations, in which Agricola, who had in the mean time acknowledged the authorship of the theses, was at first treated tenderly; but afterward Luther used harsh language, classing Agricola with the Anabaptist fanatics. In 1540 Agricola again retracted, and was reconciled with Luther. The controversy was however carried on by others in Germany.—Antinomianism appeared in England during the protectorate of Cromwell, some of the sectaries maintaining that "as the elect cannot fall from grace nor forfeit the divine favor, any wicked actions which they may commit are not really sinful; and that, consequently, they have no need to confess their sins or to break them off by repentance." In the 17th century antinomianism again made its appearance in England, its supporters maintaining that it was a logical consequence from the doctrines taught by Calvin. It reappeared in the 18th century to a considerable extent among the followers of

Wesley. It was earnestly opposed by Wesley and John Fletcher, the latter of whom wrote "Checks to Antinomianism," probably the ablest of his works. In America antinomianism properly so called has never been maintained except by isolated individuals, although it is sometimes used by polemicists as a term of reproach. Among the prominent writers in English who have opposed antinomianism are John Wesley, John Fletcher, Robert Hall, and Andrew Fuller.

ANTINOÛS, a beautiful Bithynian youth, the favorite of the emperor Hadrian, accompanied that prince on his journey through Egypt, and was drowned in the Nile A. D. 132. According to Dion Cassius, he drowned himself under the following circumstances: The oracle at Besa had informed the emperor that a great danger which was threatening him could only be averted by the immolation of the person whom he loved most fondly. The youth, hearing this, threw himself into the Nile as a voluntary sacrifice. To perpetuate his memory, Hadrian built near Besa the magnificent city of Antinopolis or Antinoë in Middle Egypt, and caused a newly observed star to be called by his name. Antinoüs was deified, mysteries in his honor were celebrated at Mantinea, and statues of him erected throughout the Roman world.

ANTIOCH (anc. *Antiochia*; Turk. *Antakia* or *Antakieh*), a city of Syria, was the most magnificent of 16 cities of the same name built by Seleucus Nicator, about 300 B. C., in memory of his father Antiochus. It was distinguished by the appellation Epidaphnes, which it received from the neighboring grove of Daphne, containing a magnificent temple of Apollo. (See *DAPHNE*.) Antioch was advantageously situated, in communication with all the trade of the Mediterranean, and conveniently approached by caravans from the east. It was the flourishing capital of the Seleucid empire, and subsequently the favorite residence of wealthy Romans. In the time of Chrysostom its free population was computed at 200,000, and the Christian church, which had been established here soon after the martyrdom of Stephen, then numbered 100,000. The inhabitants were distinguished both for their intellectual and their luxurious character. A high Greek civilization was mingled with various Asiatic elements; a passionate love of frivolous amusements was closely associated with a strong tendency to metaphysics and a solemn faith in astrology. To their addiction to scurrilous wit and the invention of nicknames may be attributed the appellation "Christians" first given in this city to the followers of Jesus Christ. For 600 years Antioch deserved the title which Pliny gave it of "queen of the East." About 145 B. C. tens of thousands of the inhabitants, who had revolted against Demetrius II. and besieged him in his palace, perished in a bloody struggle with the Jewish force sent for his rescue by Jonathan, one of the Maccabees. In A. D. 115 Antioch was almost utterly ruined by an

earthquake, but was rebuilt in its ancient splendor by the contributions and influence of the emperor Trajan. In 155 it was destroyed by fire, and restored by Antoninus Pius. On the decline of the Roman empire it suffered severely in the wars with Persia, being sacked by Sapor I., Chosroës I., and Chosroës II. In 331 it was visited by a famine so dreadful that a bushel of wheat sold for 400 pieces of silver. The same calamity befell the city in the reign of Julian, and again in that of Theodosius. The inhabitants were severely punished by Theodosius in 387 for resisting the payment of an extraordinary tribute. In the years 458, 526, and 587 Antioch was visited by earthquakes, and on each occasion nearly ruined. That of 526 was the most destructive of life of any on record. Gibbon states that 250,000 persons perished. In 638 it fell into the hands of the Saracens, and about 975 was reannexed to the Byzantine em-

pire, in 1098 was taken by the crusaders, and in 1268 its power was extinguished by Sultan Bibars. (See BOHEMOND.) The bishop of Antioch in the 5th century received the title of patriarch, and ranked next to the bishops of Rome, Constantinople, and Alexandria. In the Greek church he still ranks immediately after the patriarchs of Constantinople and Alexandria. In the Roman Catholic church four bishops bear the title of patriarch of Antioch, those of the Maronite, United Greek, United Syrian, and Latin rites. None of the present patriarchs of Antioch reside in Antakieh.—Antakieh, or modern Antioch, is situated on the S. bank of the Orontes, which at this place is about 120 feet wide, 55 m. W. of Aleppo; pop. about 12,000. S. of the city is a high mountain, the sides of which Ibrahim Pasha fortified to command the town. It has a number of insignificant mosques with low min-

City of Antioch.

rets, and several Christian churches. Most of the Christians in Antioch and the neighboring mountains are Armenians, among whom the American missionaries have made many converts. Silk is much cultivated here, and exported in a raw state to France. Oil, soap, and leather are also manufactured, and grain, honey, and butter are exported in large quantities. The fertile plains of Antioch are quite uncultivated, being subject to raids by the Turcoman robbers, who are more dreaded by the peasantry than the Bedouins; but on the hills around are numerous plantations of figs, olives, and vines. Large herds of horses in a half wild state roam the plains; they are reared by the Turcomans for the Syrian markets. In 1822 the town again suffered severely from an earthquake; and on April 3 and 10, 1872, heavy shocks occurred, overthrowing part of

the walls, rending the ancient Roman bridge in several places, and destroying a great number of the houses in the city and in the surrounding villages and several thousand lives.

ANTIOCH COLLEGE, a seat of learning at Yellow Springs, Green county, Ohio, 75 m. N. E. of Cincinnati. It was incorporated in 1852, and its buildings, erected at an expense of \$150,000, occupy a beautiful and healthful situation. The college is designed to give education as cheaply as possible to the people of the West; to open every opportunity equally to men and women; and to be religious but not sectarian. It requires sound moral character in the students, not less than scholarship. Horace Mann was its president from 1853 till his death in 1859, when he was succeeded by Thomas Hill, D. D., who held the position until elected president of Harvard college in 1862.

In 1866 George W. Hosmer, D. D., of Buffalo, N. Y., was chosen president, but resigned the office in 1872, and was succeeded by Prof. Edward Orton. The education of the two sexes together has proved successful. About one third of the pupils have been women, and the moral tone of the students has been excellent. The average number in attendance in all departments for the last five years has been about 165. The highest cost of tuition in the college course is \$30 a year. There are seven professors and four assistant female teachers. The college has an endowment of \$103,000. By a recent vote of the board of trustees, an offer is made to the high schools of Ohio of free tuition to one young man and one young woman in each school yearly, who shall be well prepared to enter the freshman class. A preparatory school and a musical institute are attached to the college, and under the supervision of the faculty.

ANTIOCHUS, the name of several kings of Syria, of whom the following are the most important in its history: **I. Antiochus I., Soter**, born about 325 B. C., died in 261. He was the son of Seleucus Nicator and Apama, the daughter of the Persian satrap Artabazus. At the battle of Ipsus he commanded the cavalry of his father, and was routed by Demetrius Poliorcetes. He fell ill through love for his stepmother Stratonice, and his father not only abandoned to him the object of his desire, but abdicated a portion of his dominions in his favor. He joined his father in his expeditions into the countries lying between the Indus and the Caspian. On the assassination of Seleucus in Thrace (280) he inherited all his dominions. In his reign a division of the Gauls, who had ravaged Macedonia, Hellas, and Thrace, penetrated into Asia Minor, and settled permanently in northern Phrygia, subsequently known as Galatia. Antiochus gained a brilliant victory over them in 275, from which he took his surname of Soter (Saviour). He disputed the throne of Macedonia with Antigonus Gonatas, the son of Demetrius Poliorcetes; but the matter was arranged by Antiochus retaining the throne and marrying the daughter of Antiochus. After an unsuccessful war with Eumenes, king of Pergamum, he put to death his eldest son, Ptolemy, who had revolted against him. He was killed by a Gaul in a battle near Ephesus. **II. Antiochus III., the Great**, son of Seleucus Callinicus and Laodicea, born about 238 B. C., slain in 187. He succeeded his brother Seleucus Ceraunus at a time when his kingdom was in a disorganized condition. After reducing a revolt of the governors of Media and Persia, and of Artabazanes, governor of Atropatene, he was defeated by Ptolemy Philopator near Gaza (217) in an attempt to secure possession of Coele-Syria and Palestine, but recovered his laurels by suppressing the rebellion of his cousin Achæus, whom he besieged in Sardis, captured by treachery, and put to death, thus reannexing a considerable portion of Asia Minor to the Syrian mon-

archy (214). In pursuance of his scheme of restoring his kingdom to the position it held at the death of its founder, Seleucus Nicator, he turned his arms against Parthia, and reduced Arsaces III. to vassalage. He was unsuccessful against Euthymedus, king of Bactria. Crossing the mountains of Paropamisus (Hindoo Koosh) into India, he made a treaty of alliance with the king of the Punjaub, and directed his march homeward through the provinces of Arachosia, Drangiana, and Carmania, and reestablished the Syrian supremacy in those regions. For this seven years' expedition he received from his subjects the surname of the Great. Soon after his return to Antioch (205), Ptolemy Philopator died, and his son Ptolemy Epiphanes, then five years old, succeeded to the throne of Egypt. Antiochus thereupon entered into an alliance with Philip of Macedonia to overrun and partition Egypt. He quickly gained possession of Palestine and Coele-Syria, and after a great victory near Paneas was received by the Jews in Jerusalem with great enthusiasm. Learning the defeat of his ally Philip by the Romans at Cynosephalæ in 197, he made peace with Ptolemy, proceeded with a fleet along the coast of Asia Minor, reducing many of the Greek cities there, crossed the Hellespont, and took possession of the Thracian Chersonese. The Roman senate sent an ambassador in 196 to demand that he should restore what he had taken from Philip and Ptolemy, whose guardianship the Roman people had just assumed. They also demanded immunity for their ally Attalus, king of Pergamum. Antiochus replied that as he did not seek to interfere with what the Romans did in Italy, they must not trouble him in Asia. In the following year (195) Hannibal, driven from Carthage, took refuge with Antiochus at Ephesus. Hannibal's advice was to carry the war immediately into Italy, but Antiochus did not move till 192. Then he crossed over into Greece at the invitation of the Ætolians, who were in arms against the Romans. He brought only 10,000 men with him, but was chosen commander-in-chief by the Ætolian assembly, and began by making Philip of Macedonia his enemy instead of his friend. After capturing Eubœa, instead of pressing forward, he wasted his time in treating about the surrender of a number of little cities, fell in love with a Eubœan damsel and married her, and spent the winter at Chalcis in a round of dissipation, in which his army shared. The Roman consul Acilius Glabrio, with Cato for his legate, now advanced upon him. He made a stand at Thermopylæ, was entirely routed, and barely escaped with his new wife (191). The next year Lucius Cornelius Scipio took the conduct of the war, with his brother Africanus as his lieutenant. Disheartened and panic-struck by the defeat of his fleet, Antiochus withdrew his troops from Sesstos and Abydos, and the other fortified maritime cities of Asiatic Greece, which might have held the Romans in check. Thus the latter had free passage into Asia. The two ar-

mies met at Magnesia near Mt. Sipylus; that of Antiochus numbered 70,000 men, that of the Romans 30,000. The Syrians were thoroughly defeated and cut to pieces, and Antiochus was compelled to submit to whatever terms the Romans chose to impose. These terms were to resign the provinces west of the Taurus, to pay a large sum for the expenses of the war, to deliver up to the Romans his elephants and ships of war, and to surrender Hannibal and the other anti-Roman refugees. Hannibal and another were allowed to save themselves by flight; the rest were given up together with hostages for the execution of the treaty. One of these hostages was Antiochus Epiphaneus, the king's younger son. In collecting means to pay the indemnity, he plundered a wealthy temple in the province of Elymais, upon which the indignant people rose and massacred him and his attendants. **III. Antiochus IV., Epiphaneus**, or the Illustrious, second son of the preceding, succeeded his elder brother Seleucus Philopator in 175 B. C., died in 164. He was kept as hostage at Rome until his brother sent his own son Demetrius to replace him. He recovered Cœle-Syria and Palestine in a single campaign (171), overran all Egypt except Alexandria, took captive the young king, Ptolemy Philometor, and in 170 sacked Jerusalem and plundered the temple, as related in the book of the Maccabees. He undertook four expeditions into Egypt, and would have annexed that country had not the Roman ambassadors met him on the last occasion (168) and ordered its immediate evacuation. On his return home he commenced that great persecution of the Jews which is related in the 2d book of the Maccabees, during which time the service of the temple was broken off for three years. He set up the statue of Jupiter Olympus there, and desired to introduce the worship of the Greek deities, but was thwarted by the insurrection of Mattathias and his sons the Maccabees. After a frustrated attempt to plunder a temple in Elymais, he became raving mad, in which condition he died. His subjects called him, in parody on his surname, Epimanes, the madman.

ANTIOQUIA, one of the nine states of the United States of Colombia, between lat. 5° 3' and 8° 9' N., and lon. 74° 3' and 76° 13' W., touching the gulf of Darien on the N. W., and bounded by the states of Bolívar, Santander, Cundinamarca, Tolima, and Cauca; area, 24,823 sq. m.; pop. in 1870, 365,974, about 20 per cent. white, the remainder mestizos (mixed white and Indian), mulattoes, and Indians, chiefly civilized. The central range of the Andes spreads out over nearly the whole state, terminating in its E. and N. E. portions. The river Cauca flows through its entire length, and the Magdalena forms the E. boundary, and is navigable for steamers of light draught. Antioquia is rich in gold, and although the mines and washings are but little worked, the annual produce is estimated at \$2,500,000. The soil is ex-

trremely fertile, and the valleys lying between the various mountain ranges abound in cattle. Springs impregnated with iodine abound throughout the state, to which is attributed the exemption of the inhabitants from goitre, which prevails in other parts of the republic. The principal cities are Medellín, the capital, Cáceres, Remedios, and Zaragoza.

ANTIPAROS (anc. *Oliarus* or *Olearus*), an island of the Grecian archipelago, one of the Cyclades, forming part of the eparchy of Naxos, Greece, about 3 by 7 m., separated from Paros by a strait 1½ m. wide; pop. about 1,000. Cotton, barley, and wine are produced in small quantities. The island contains masses of white marble, and is celebrated for a grotto, 120 yards long, 113 wide, and 60 feet high, situated 2 m. from the sea, at an elevation of 500 feet. It consists of an immense marble arch, the roof, sides, and centre of which are covered with stalactites and dazzling crystallizations assuming the shapes of columns, screens, flowers, trees, &c. The stalactites hanging from the roof unite in several places with stalagmites rising from the floor, so that the arch is apparently supported by a continuous series of pillars. The grotto is entered by a natural arch of rugged rock, overhung with trailing plants.

ANTIPAS, Herod. See HEROD.

ANTIPATER, a Macedonian general, one of the successors of Alexander, born about 390 B. C., died in 319. He was educated by Aristotle. Appointed viceroy of Macedonia and Greece when Alexander made his expedition into Asia, he defeated the Spartans and slew their king Agis in 331. Alexander became distrustful of him, and ordered him to be superseded, but died before the change could be made. At the division of the empire, Antipater received Macedonia and Greece, and the guardianship of the future child of Alexander by Roxana. When the death of Alexander became known, the Athenians determined to strike again for liberty, and made an alliance with the Ætoliens, Thessalians, and all the Greeks north of the isthmus except the Bœotians, and with the Peloponnesians who were not of the Lacedæmonian party. The allies, under the Athenian Leosthenes, were at first successful; but Antipater, having been reënfined, gave them battle in 322 at Crannon in Thessaly, and, though the victory was not complete, compelled them to sue separately for peace. The Athenians and Ætoliens, deserted by their allies, were unable to continue the struggle. Antipater demanded the surrender of Demosthenes and Hyperides, the two democratic orators, put a Macedonian garrison in Murechia to act in concert with Phocion and the Athenian conservative party, broke up the democratic constitution of Athens, and left the government in the hands of about 9,000 citizens who were possessed of a property qualification, and were disposed to peace, banishing most of the other citizens to various parts. He drove the Ætoliens into their mountains, and

starved them into submission. After the death of Perdicas (321), Antipater made a new division of the provinces, giving a part of the territory of Perdicas to Antigonous, part to Lysimachus, and part to Seleucus.

ANTIIPHON, an Athenian orator, son of Sophilus the sophist, born at Rhamnus in Attica about 480 B. C., died in 411. He taught rhetoric at Athens, composed orations for others, was the first who received money for such services, and is believed to be the first who subjected the art of oratory to strict theoretical rules. He was the most active leader in the revolution which established the oligarchy of the 400 in 411; and his only public speech was the one he delivered in his own defence on its overthrow in the same year. Thucydides called it the ablest that was ever made in similar circumstances, but it is now lost. Antiphon was condemned to death. There are 15 of his orations extant, the best edition of which is that of Dobson (London, 1828).

ANTIIPHONY (Gr. ἀντιφωνία, response), the response which, in the Roman Catholic service, one side of the choir makes to the other in the chant. Antiphonal or responsive singing is the most ancient form of church music, and is said by the historian Socrates to have been first introduced among the Greeks by Ignatius, and among the Latins by St. Ambrose. The chanting of the psalms alternately is doubtless older than Christianity, and prevailed in the temple service of the Jews, many of the psalms being composed in alternate verses as if with a view to this mode of singing. In the cathedral worship of the Catholic church, two full choirs are stationed one on each side of the sanctuary, one of which, having chanted a verse, remains silent, while the opposite choir replies in the verse succeeding; and at the end of each psalm the *Gloria Patri* is sung by the united choirs in chorus.

ANTI-RENTISM. The Dutch West India company authorized its members in New York to take up land upon the banks of the streams and rivers, on condition of introducing within a limited time 50 settlers for every mile of land. The proprietor was invested with the title and privileges of a lord patroon or protector, and his colony or manor was governed by the same customs and laws as were the feudal manors of the United Provinces. After the revolution a very large proportion of the land in the settled parts of New York was held by the patroons, and the cultivators occupied their farms on leases for one or more lives, or from year to year, stipulating for the payment of rents, dues, and services, copied from the feudal tenures of England and Holland. In 1779 and 1785 laws were enacted by the legislature of the state abolishing feudal tenures, but the proprietors of manor grants, unwilling to give up all their feudal claims, contrived a form of deed by which the grantees covenanted to perform services, and pay rents and dues, precisely similar to the feudal incidents thus abolished.

The counties of Albany, Rensselaer, Columbia, Greene, Ulster, Delaware, Schoharie, Montgomery, Herkimer, Otsego, and Oneida include within their limits most of these manors. In 1839 associations were formed to devise means for getting rid of these burdens, and soon became known as anti-rent associations. The anti-rent feeling manifested itself in open resistance to the service of legal process for the collection of manorial rents. The first conflict which awakened general attention happened in the town of Grafton, Rensselaer county, where a band of anti-renters in disguise killed a man named Smith during an altercation on the highway. A legal investigation, at which more than 200 persons were from time to time examined, failed to disclose the author of the deed. In his messages of 1841 and 1842, Gov. Seward discussed the grievances complained of by the tenants. He recommended a reference of the matters in dispute to arbitrators, and appointed three men to investigate and report to the legislature. This commission failed to accomplish anything. The dissatisfaction and excitement increased, until, after a tragical affair at Andes in Delaware county in 1845, Gov. Wright issued a proclamation, declaring the county in a state of insurrection. The trials and convictions at Delhi in that county, and the convictions of certain anti-renters at Hudson, Columbia county, for conspiracy and resistance to law, put an end to operations by the disguised bands. The anti-rent associations determined to form a political party, whose policy should be to elect all town and county officers from their own ranks, and to vote for no state, civil, judicial, or executive officers unfriendly to them, or pledged to their cause. In the legislatures of 1842-'7 about one eighth of the members were elected in the interest of the anti-renters. In the constitutional convention of 1846 some of the ablest men were avowedly anti-renters, or advocates of their measures and principles. Their influence procured the insertion of a clause in the new constitution abolishing all feudal tenures and incidents, and forbidding the leasing of agricultural land for a term exceeding 12 years. The legislature at successive sessions passed laws which bore heavily upon the landlord interest, and tended gradually to ameliorate the condition of the tenants. In 1846 Gov. Wright, who was a candidate for reelection, was defeated by 10,000 majority for John Young, whom the anti-renters had nominated. Gov. Young pardoned from the state prison all the so-called anti-rent convicts, on the ground that their offences were rather political than criminal, and that it was the wise policy of all good governments to forgive and restore to citizenship political offenders, after the law had been vindicated and order and peace restored. After 1847 the excitement died out, the anti-rent influence ceased to be a disturbing force in politics, and the anti-rent organization contented itself with efforts to contest in the courts the

validity of the titles of the landlords, and the legality of the conditions and covenants contained in the manor grants.

ANTISANA, a volcanic mountain of Ecuador, in the eastern Cordillera, 35 m. S. E. of Quito, according to Humboldt, 19,148 ft. high; according to Wisse, 19,279. An eruption in 1590 is recorded; and Humboldt saw smoke issuing from several openings in 1802. Four immense lava streams descend from the snowy summit, one of which, the Volcan de Ansango, is 10 m. long and 500 ft. deep. The lava is mainly a black, cellular, trachytic porphyry. But the volcano is now dormant, if not extinct. On its side is Lake Mica, near which is the celebrated Hacienda, one of the highest habitations in the world and the centre of an extensive corral. Humboldt made its altitude 13,465 feet; Bous-singault, 13,356; Orton, 13,300.

ANTI-SCORBUTICS. See SCURVY.

ANTISEPTICS (Gr. *ἀντί*, against, and *σηπτός*, putrid), substances or means which prevent or arrest putrefaction. Putrefaction is a process which highly complex organic bodies undergo when subjected to the proper conditions of heat, moisture, and air, and no longer controlled by the laws of vital chemistry. Nitrogenous or albuminoid bodies are essential to this process, in which they play the double part of being themselves decomposed and, by an imperfectly understood action called catalysis, exciting allied changes in other bodies. The growth of living infusorial organisms holding a very low position in the scale of animal or vegetable life, called vibrios and bacteria, is a frequent if not invariable accompaniment of this process; but it is still a question how essential they are in its production. The methods of preventing organic decomposition depend upon the removal of some one or more of the conditions necessary for its accomplishment. The temperature may be above or below the limits at which putrefaction can go on. The preservative effect of cold, and especially of dry cold, is well known, and exemplified in the keeping of meat and fruit on ice or in ice houses. Animals have been found undecomposed in the ice of Siberia, which belong to extinct species and which must have been embalmed in ice for ages. A boiling temperature coagulates albumen, kills infusorial organisms, and temporarily arrests putrefaction, until the material receives a new ferment from without. The exclusion of air, as in the process of canning fruit and meat, renders the result more permanent. Many substances withdraw water from the tissues, and also from the infusorial organisms, thus causing them to shrivel up and lose their activity. Such are sugar, glycerine, alcohol, and many salts, as common salt, saltpetre (nitrate of potassa), and alum. Fruits are largely preserved in sugar; many medicinal fluid extracts may be made with glycerine; and anatomical specimens may be preserved almost indefinitely in glycerine or alcohol. Salt and saltpetre are of the

highest value in the preservation of meat. If the water is simply driven off by the heat of the sun and atmosphere, meat may be kept unchanged for a long time in a dry climate. Several of the agencies first mentioned, such as boiling water, alcohol, and some salts, as well as corrosive sublimate, chloride of zinc (Burrnett's disinfecting fluid), and tannin, act by coagulating and rendering chemically inert albuminous substances. Corrosive sublimate is used but little except for anatomical purposes. Chloride of zinc is an excellent disinfectant for ships, hospitals, dissecting rooms, and water closets, and is also used to preserve bodies for dissection. Tannin forms with the gelatine of the skin, in leather, one of the most enduring of organic compounds. Prof. Brunetti of Padua has used tannic acid very successfully in the preservation, as anatomical specimens, of various internal organs. Bodies have been found perfectly preserved in peat bogs, that must have been undergoing the tanning process for hundreds of years. Many of the most useful antiseptics act not only in one or more of the ways mentioned, but also either as poisons to the infusoria accompanying decomposition, or as opposing the catalytic action of ferments. Quinia, for instance, has been found to have both these properties in a high degree, killing infusoria immediately in the proportion of one part to 800, in some minutes at 1 to 2,000, in some hours at 1 to 20,000, and preventing or retarding the formation of carbonic acid from sugar, the reaction of emulsine upon amygdaline, and of ozone upon guaiacum. As a preservative against actual putrefaction, it was found, weight for weight, less efficient than corrosive sublimate. Carbolic acid, creasote, chloroform, and perhaps the volatile oils, act in this way. Carbolic acid has been largely used of late years as a surgical antiseptic dressing, in watery solution, 1 to 30; diluted with glycerine, with alcohol, with oil, as putty, or as plaster with shellac. The antiseptic treatment demands that all wounds should be carefully protected from the air by some of the forms of carbolic acid dressing just mentioned, even a finger used in examination or an amputating knife being dipped in carbolic acid oil, lest they should carry living germs to the wounded surface. The action of creasote finds useful application in the smoking of meat. Volatile oils and resins were probably the active agents in the ancient process of embalming. Chlorine, and sometimes iodine, act as disinfectants by withdrawing hydrogen from products of putrefaction, allowing the nascent oxygen and other remaining elements to form simpler and more stable combinations, and as antiseptics by poisoning infusoria or destroying the activity of ferments.

ANTISPASMODICS, the means of removing spasm. Spasm or cramp occurs in muscular structures, and is caused by irritation of the nerves. Spasm consists in an irregular and sometimes excessive action of a group of mus-

cles, or a single muscle, or some particular fibres only of a muscle; and various names are applied to spasms of the different muscles or sets of muscles. The conditions giving rise to spasm are various, and affect one or more parts of the nervous circuit, which may be conceived to consist of an afferent or sensitive fibre conveying sensitive impressions to a nervous centre, the latter transforming them into motor impulses, which, passing out by an efferent or motor fibre to a muscle, stimulates it to contraction. When these contractions take place irregularly, or in a degree disproportionate to the stimuli giving rise to them, or when they arise from stimuli which should not normally occasion them, and more especially when they take place unconsciously or involuntarily, they become spasms. They often arise from organic disease of the nervous centres, as in inflammation of the brain or spinal cord, or their membranes, from tumors and hemorrhages, as possibly in chorea or St. Vitus's dance. A poisoning of the centres by abnormal constituents of the blood, as in Bright's disease, also gives rise to them. The nervous centres, especially the spinal cord and medulla oblongata, and the sensitive nerves, may become too sensitive, as in tetanus or lockjaw, poisoning by strychnia, and epilepsy. Other forms of spasm are due to special local irritations, as colic to improper food, uterine colic to the introduction of fluids into the uterus for therapeutic purposes, asthma to certain states of the atmosphere, cramps of the feet and legs to cold or constrained positions. In treating these various affections, various drugs may be used, which so far deserve the name of antispasmodics. Heat often relieves many spasms, as colic, cramps of the legs and feet, and the general convulsions of children from intestinal irritation, and may be applied in the form of hot baths or hot fomentations. Abnormal excitability of the spinal cord and medulla oblongata is diminished by bromide of potassium, which does excellent service in epilepsy, and sometimes by belladonna. The newly discovered hydrate of chloral has also the same property. Opium relieves the intense pains of uterine or other colic, and relaxes spasmodically contracted intestinal or uterine fibres. Ether and chloroform, inhaled, not only diminish but nearly destroy the activity of the nervous centres; they control all the voluntary muscles, and are the most powerful antispasmodics which can be used in any form of spasmodic disease. Unfortunately, their effect is often temporary. It is possible that the *physostigma* (Calabar bean) and woorara (South American arrow poison) may be practically used in some convulsive diseases. In organic diseases of the brain and cord, the disease rather than the symptom deserves attention. The substances to which the name antispasmodics in the narrowest sense is applied are used either in the treatment of colic, of some children's diseases, in many hysterical affections, and some others. They are the "volatile

oils," such as mint, lavender, &c., derived chiefly from the tribe of plants called *labiate*; cajeput oil, from the *myrtaceæ*; dill, anise, fennel, &c., from the *umbellifere*—from which tribe also are derived the fœtid gum resins, such as asafetida, galbanum, ammoniac, &c. These, with valerian, myrrh, and camphor, derived from the vegetable kingdom; musk and castoreum, from the animal kingdom; cyanide of iron and the oxides of bismuth and zinc, from the mineral kingdom, are among the most valuable antispasmodics. In the treatment of hysteria, moral, tonic, hygienic, and sometimes surgical measures are of far greater importance than antispasmodics, which at the most can only temporarily relieve symptoms.—Spasmodic affections may be complicated with inflammation, and in that case they require most careful and somewhat different treatment. They may also occur in debilitated constitutions, or in persons of full habit; and here again the treatment differs. Thus the medicines classed under the head of antispasmodics are of small importance in comparison with a correct diagnosis and an appropriate mode of treatment in each special form of spasmodic affection.

ANTI-SLAVERY. See SLAVERY.

ANTISTHENES, an Athenian philosopher, the founder of the sect of the Cynics, flourished about 380 B. C. He was a pupil of Gorgias, and afterward one of the most faithful disciples of Socrates, remaining with him through all his sufferings, and being present at his death. He began to teach his new doctrines in the Cynosarges, a gymnasium near the temple of Hercules, set apart for the instruction of the sons of Athenians by foreign wives; Antisthenes himself was the son of an Athenian citizen and a Thracian (or according to some authorities a Phrygian) woman. From this gymnasium the followers who soon surrounded him probably took their name of Cynics. He taught that the highest virtue consisted in self-denial, independence of outward forms, social usages, and the comforts and luxuries of civilization, and in despising riches, honors, and human knowledge. His principal disciple was Diogenes. His works, of which only trifling fragments remain, were of a polemic character, bitterly assailing many of his contemporaries.

ANTITAUROS. See TAURUS.

ANTITRINITARIANS. See UNITARIANISM.

ANTIUM, an ancient city of Latium, built on a rocky promontory which projects into the Mediterranean, 32 m. S. of Rome. One legend ascribed its foundation to a son of Ulysses and Circe, another to Ascanius. No authentic record shows even by what people it was founded. In the time of Tarquinius Superbus, who annexed it to the Latin league, it was inhabited by a mixed race who practised piracy and carried on a limited legitimate commerce. They favored the Volscians, and were only kept among the cities subject to Rome by strong garrisons and bodies of Roman colonists,

who were sent to Antium from time to time. Later, though at exactly what period is not known, it fell entirely into the hands of the Volscians, and for some time vigorously aided them, according to Livy, in their wars against the Romans. In 468 B. C. it was retaken by the latter, and held till 459, when it again revolted. For a century it was the chief Volscian city, but in 338 it was a third time overcome and garrisoned by Rome. The city continued prosperous, partly because of its excellent harbor, partly because of its popularity as a summer resort for the citizens of Rome. Cæcilia and Nero were born in Antium, and Cicero had a villa there. A vast circus, and temples of Venus, Æsculapius, Apollo, and Fortuna, as well as one which was the seat of a celebrated oracle, added to the magnificence of the city. Its prosperity declined with the decline of the western empire, and it was laid waste by the Saracens during their incursions, so that by A. D. 950 it had become a petty fishing village. Pope Innocent XII. (1691-1700) made an attempt to restore something of its beauty, but with only temporary success; and the town, known in modern times by the name of Porto d'Anzo, remained almost deserted until the accession of Pius IX. This pope built there a very beautiful church and a villa which was for many years his favorite summer residence. Other beautiful villas have sprung up around it, and Porto d'Anzo is now a town of about 1,000 inhabitants, occupying almost the centre of the site of ancient Antium, the ruins of which are everywhere visible. Among these ruins were found the Apollo Belvedere and the "Fighting Gladiator" of the Borghese collection, with other art treasures.

ANT LION, or **Lion Ant**, a species of neuropterous insect, of the genus *myrmeleon* (Linn.), which has become celebrated for the singular manner in which the larva obtains a living prey. The perfect insect (*M. formicarium*, Linn.) resembles a small dragon fly, has a good power of flight, and is generally found in the warmer parts of Europe. The larva is about

half an inch long, of an oval depressed form, and grayish sandy color; the small head is armed with two strong and long mandibles, serrated and pointed, with which it seizes and

sucks the juices of its prey. The powers of locomotion being small, it has recourse to artifice to entrap insects. It makes a funnel-shaped excavation in sandy soil, with loose and crumbling sides, and buries itself, all but the head, at the bottom, waiting for a victim. If an ant or small insect approaches the edge, the sand gives way and it rolls down within reach of the expectant jaws; after the body has been drained it is cast out by a toss of the head. If the insect be large or likely to escape, the ant lion throws repeated showers of sand upon it by means of the head, until it falls exhausted and defenceless to the bottom of the pitfall. Sometimes a revengeful wasp, well-armed bee, or mail-clad beetle falls into the snare, and the sting of the first two or the powerful jaws of the last often prove fatal to the ant lion. The larva state continues about two years, when a cocoon is spun, in which it is changed into an inactive nymph; the perfect insect comes out in two or three weeks, and lays the eggs for a new brood in dry and sandy places suited for the operations of the larvæ. There are other species both in the old world and the new, all with similar habits.

ANTOINE DE BOURBON, duke of Vendôme, and afterward king of Navarre, the father of Henry IV. of France, born in 1518, died Nov. 17, 1562. He married in 1548 Jeanne d'Albret, only child of Henry II., king of Navarre, and assumed the title of king in her right. Like his brother, the duke of Condé, he embraced Protestantism. After the accession to the throne of France of the young king Francis II. (1559), he endeavored to obtain the control of the affairs of that country, but failed through his want of energy and perseverance. On the death of Francis in 1560, he was made lieutenant general of the kingdom, and adviser to the queen mother (Catharine de' Medici), during the minority of Charles IX. He then abandoned his former associates and religion, and allied himself with the duke of Guise and the constable de Montmorency. Upon the breaking out of the civil war in 1562, he commanded the royal forces, and died of a wound received at the siege of Rouen.

ANTOMMARCHI, Carlo Francesco, physician to Napoleon at St. Helena, born in Corsica, died at San Antonio de Cuba, April 3, 1833. He was professor of anatomy at Florence, where in 1818 Letitia Bonaparte sent Cardinal Fesch to induce him to go to St. Helena. The emperor at first treated him with marked coldness, but afterward honored him with implicit confidence, and in his will left him 100,000 francs. On the emperor's death Antommarchi went to Paris, where he published *Les derniers moments de Napoléon* (2 vols., Svo, 1823). Nearly nine years after Napoleon's death Antommarchi produced a cast of his head, which purported to have been taken after death. The authenticity of this cast was hotly contested, especially by the advocates of phrenology, against whom it was used as an argument.

Antommarelli in consequence of these disputes came to America about 1836, and practised homoeopathy at New Orleans and Havana.

ANTONELLI, Giacomo, an Italian cardinal and statesman, born at Sonnino, near Terracina, April 2, 1806. He was educated at the great seminary of Rome, and having early distinguished himself by his ability, he was raised to the prelaey, after taking orders, and appointed by Gregory XVI. to various civil offices, attaining in 1845 to the post of minister of finance. After the accession of Pius IX. he was made cardinal (June 12, 1847), and in 1848 prime minister, in which position he won at first the favor of the popular party. Though continuing to be the pope's chief political adviser, the opponents of innovations soon compelled him to make place for Mamiani. After the assassination of the latter's successor, Rossi, Antonelli urged Pius IX. to leave Rome, and joined him at Gaeta (November, 1848), where he conducted the negotiations which resulted in the pope's return to his capital (April 12, 1850) under the protection of the French army of occupation. Antonelli was now made secretary of foreign affairs, in which capacity his retrogressive policy exasperated the liberals, and even led to remonstrances on the part of foreign powers, but without shaking his position. He protested in vain against the progress of events in Italy, reorganized the civil administration on the most reactionary basis, and was opposed in his absolute policy even by some of his colleagues in the papal government, the principal of whom, Mgr. de Merode, minister of war, was removed in 1865. In 1867 he was made *curator ad interim* of the university of Rome. In January, 1868, by the death of Cardinal Ugolino, he became dean of the order of cardinal deacons. After the evacuation of Rome by the French in August, 1870, he appealed to various foreign powers for assistance, and remonstrated against the success of Victor Emanuel, who made his formal entry into Rome Nov. 21, 1871. An attempt upon his life was made in 1855.

ANTONELLO DA MESSINA, an Italian painter, born at Messina in 1414, died about 1493. According to Vasari and other authorities, he was the first Italian who painted in oil, learning the art under Van Eyck at Bruges. Before his journey to Bruges, he had already acquired some fame at Messina, Rome, and Palermo, which became more firmly established on his return, when he worked for some time at Milan and at Venice to some extent in portrait painting, but chiefly in religious pictures.

ANTONINUS, Marcus Aurelius, a Roman emperor, son-in-law and successor of Antoninus Pius, born A. D. 121, ascended the throne in 161, died March 17, 180. His original name was Marcus Annius Verus. After the death of Ceionius Commodus, better known as Verus, Hadrian selected Antoninus Pius to succeed him, and caused the latter in his turn to adopt Marcus Annius and Lucius Verus, the son of Commodus, as his ultimate successors. During

the reign of Antoninus Pius, who had given to him his daughter Faustina in marriage, Marcus distinguished himself principally by his studies in philosophy, having assumed the mantle of the Stoics in his 12th year; while Verus so far disgraced himself by his early profligacy, that his adoptive father disinherited him, and, procuring the nomination of Marcus Aurelius as sole successor by the senate, associated him with himself in the empire. On his accession, however, Marcus Aurelius, who now assumed the name of Antoninus, gave Verus an equal share of the government. Shortly after his accession a war broke out with the Parthians in the east, the command of which, nominally given to Verus, was virtually held by his lieutenants, the principal of whom, Avidius Cassius, overran Mesopotamia, destroyed Selencia, and penetrated as far as Babylon, while one of his colleagues made himself master of Armenia, replaced the rightful king of the Parthians, Sozimus, on the throne, and reduced Vologeses, his rival and the instigator of the war, to sue for a dishonorable peace. This outbreak was followed, or rather interrupted, by yet more dangerous hostilities in the north, extending from the sources of the Danube to the Illyrian frontier, where the barbarous tribes of the Marcomanni, Alani, Jazyges, Quadi, Sarmatians, and others, all took arms at once in such force as compelled both the emperors to proceed to the frontiers. Here they were so successful, that in 169 the enemy sued for peace, and the colleagues set out on their return for home; but Verus dying of apoplexy on their journey, and the war being renewed, Marcus Aurelius again turned his face northward, and for the next five years carried on the war in person in Pannonia, without ever returning to Rome; enduring the greatest hardships with the serenity of a philosopher, while he conducted his campaigns with the skill of a soldier. On one occasion a fierce battle was fought on the surface of the frozen Danube; but the most remarkable victory was one gained over the Quadi in consequence of a sudden and terrific thunder storm, by which the Romans were saved from apparently imminent defeat, and the superstitious savages were confounded and put to rout. This victory was generally ascribed to divine interposition, the emperor and his Romans attributing it to Jupiter Tonans, and the Christians, who composed the 12th or Meletine legion, to the influence of their prayers. Eusebius goes so far as to assert that the emperor gave to that body of men the title of the "thundering legion;" but in spite of his virtues, Marcus Aurelius persecuted the Christians. His wife Faustina, learning the danger of her husband's situation, and fearing that in case of his death, and the long minority of her young son Commodus, she should sink into a private station, entered into an intrigue with Avidius Cassius, the emperor's deputy and general in Syria, promising him her hand in case of the death of Aurelius, and encouraging him in that event to seize the

reins of the government. A false report of the defeat and death of Aurelius following, Avidius Cassius assumed the purple. Despairing of pardon when he learned the falsity of the report, he persisted in his rebellion, and rapidly made himself master of several Roman provinces in Asia. While the emperor was making preparations to reduce him, the usurper was assassinated by a centurion of his own army. The conduct of Marcus Aurelius was magnanimous in the extreme. He put no one to death in consequence of the overt treason, punished but few, and burned the letters of Cassius, in order to avoid learning who had seconded or instigated him in his proceedings. Faustina, who had remained in her husband's company during these compromising events, and whose privacy he either did not suspect, or, more probably, did not choose to perceive, died in Cilicia, it was supposed by suicide. In 176 the emperor visited Rome after an absence of eight years, and celebrated his victories by a splendid triumph, and by a largess to every Roman citizen of eight pieces of gold; then having associated with himself in the sovereignty his unworthy son Commodus, and celebrated the young man's nuptials with Crispina, he marched in company with his expectant successor to conclude the war with the northern barbarians, and, in the midst of a career of uninterrupted triumph, died at Vindobona, now Vienna. Commodus was suspected of hastening his end. Marcus Aurelius was an excellent man and an admirable monarch. His whole life was a practical example of his own philosophic doctrines. The only blot on his character was a cruel persecution of the Christians in Gaul; and this is so inconsistent with the spirit of his own character, with his general principles of mildness and toleration, and with the example of his predecessor, by which he was for the most part strongly influenced, that it is difficult to explain. His "Meditations," which are still extant, would be an honor to any writer of any age, and breathe the very spirit of the religion which he persecuted. The best edition is Gataker's (4to, Cambridge, 1652). The best English translation is that of George Long, "Thoughts of the Emperor Marcus Aurelius Antoninus."

ANTONINUS PIUS, Titus Aurelius Fulvius, a Roman emperor, born near Rome, Sept. 19, A. D. 86, began to reign in 138, died in 161. He was descended from a respectable provincial family of Nemausus (Nîmes) in Gaul. He rose during the reign of Hadrian to the administration of Asia, and afterward to the management of one of the four regions of Italy, and was selected by Hadrian as his successor, wholly on account of his fitness for the dangerous eminence. His reign was eminently happy and prosperous, and so peaceful that it passed away leaving no striking mark upon the page of history. He made no effort to advance the limits of the empire, but by his firmness and wisdom deterred the barbarians on his frontiers from

disturbing the peace of the realm. The Germans, the Dacians, the Mauritanians, the Greeks, the Egyptians, all exhibited at times some tendency to give trouble; but their aggressions were easily frustrated by military demonstrations. The only commotion of any real consequence was that of the Brigantes in the northern part of Yorkshire, who repeatedly invaded the central parts of the British province, but were severely defeated by the legate Lollius Urbicus (141), who built a strong rampart of turf and stone, the ruins of which can be still traced, and are to this day known as the wall of Antoninus, from the mouth of the Esk to that of the Tweed, some distance to the north of that of Hadrian, which had been erected to prevent the incursions of the Caledonians, from the mouth of the Tyne to that of the Solway. The Parthians gave up their hostile views against Armenia, owing solely to his remonstrances; the Scythians submitted their disputes to his arbitration; and the barbarians on the upper Danube received a king of his appointment. At home he promoted literature and education, and made up for the losses of citizens through public calamities out of his private purse. He was fond of country life, and passed much of his time at his Campanian villas, never after his accession appearing at the head of his armies, and refusing to travel in his provinces, in order that they might not be subjected to the expenses of a royal progress. He died in the 75th year of his age. His reign of peace and order, and his observance of religious rites, procured for him the title of the second Numa, while he owed his surname Pius to the zeal with which he advocated in the senate the granting of divine honors to his paternal predecessor. He tolerated and protected the Christians, and received with favor the first apology for the Christian religion, addressed to him by Justin Martyr. By his wife Faustina he had two sons, both of whom died before their father, and two daughters. One of the latter, a second Faustina, inherited both the beauty and the profligacy of her mother; she was married to Marcus Aurelius Antoninus.

ANTONIO, Nicolas, a Spanish bibliographer of Flemish origin, born at Seville in 1617, died in Madrid in 1684. He lived in Rome 20 years (1659-79) as agent of Philip IV. and in other official capacities, and collected a library there said to have been only second in importance to that of the Vatican. His fame rests on his *Bibliotheca Hispana Nova* and *Bibliotheca Hispana Vetus*, which comprehend all the literary names of Spain, and in some cases of Portugal, from the 1st century to nearly the end of the 17th. In many instances biographies are given of the various authors.

ANTONIUS, Marcus, a Roman orator, born in 143 B. C., killed in 87. In 104 he was praetor, in 99 consul, and in 97 censor. He was famed for his eloquence in the forum, rendering Italy, according to Cicero, the rival of Greece. As an aristocrat, he adopted the party of Sylla,

and was put to death by Marius and Cinna when they triumphed. He is one of the interlocutors in Cicero's *De Oratore*. He was the grandfather of Mark Antony.

ANTONY, Mark (MARCUS ANTONIUS), the Roman triumvir, born in 83 B. C., died in 30. He was the son of Marcus Antonius Creticus and Julia, daughter of the former consul Lucius Julius Cæsar. During his boyhood, and while he was receiving a good education under his tutor Epidius, his father died, and his mother married Publius Lentulus, afterward strangled for his share in Catiline's conspiracy. In his stepfather's house he met the most profligate young men of Rome, and, sharing their habits of extravagance, he was obliged to take refuge from his creditors in Greece, where he completed his studies. After serving with much distinction under Gabinius in Syria (57), and in Egypt (56-55), and under Cæsar in Gaul, he returned to Rome, and was made a tribune of the people; but having strongly espoused the cause of Cæsar, and vetoed the senate's decree commanding that leader to disband the armies he had with him in Gaul, Antony was obliged to leave Rome in the disguise of a slave and take refuge in Cæsar's camp. He warmly seconded Cæsar in his subsequent subjection of Italy, and when his chief became dictator was appointed by him commander of the cavalry, and governor of Italy during the absence of the victorious leader, who was pursuing Pompey. During his governorship, Antony gave himself up to the most open licentiousness, repudiating his wife, appearing publicly in his chariot with a common courtesan, and surrounding himself with debauchees of every class. He subsequently married Fulvia, widow of Clodius. In 44 B. C. Cæsar appointed him his colleague in the government, and he in return aided his patron in many ways; once testing the popular feeling by publicly offering him an imperial crown on the occasion of the Lupercalia. On Cæsar's death, Antony at first feigned submission to the assassins; but afterward, seizing the opportunity given by their allowing him to deliver the funeral oration, he so eloquently incited the people to avenge the dictator's murder that the conspirators were driven from Rome. He was now the most powerful man in the state; but his plans for the dictatorship were checked by Cicero, who urged the claims of Octavius Cæsar; the surname Cæsar proved an excellent popular catchword, and Antony, opposing this new choice, was declared an enemy of the republic and banished from Rome, while the senate supported Octavius. After raising an army, fighting several battles, and suffering defeat at Mutina—from which place he was obliged to flee to his friend Lepidus, who was preserving an armed neutrality beyond the Alps—Antony finally effected a reconciliation with Octavius, with whom he at once joined in a scheme for the complete subjection of Rome. The triumvirate was formed soon after by Octa-

vius, Antony, and Lepidus (43). In the general slaughter of their enemies which followed, Antony caused Cicero to be murdered among the first victims. Brutus and Cassius were speedily defeated at Philippi (42) by the army of the triumvirs, and the latter now divided the empire, Antony receiving Asia, Macedonia, Syria, and Greece. He next carried on a war against the Parthians, and, when finally obliged to retire from their country, effected one of the most skillful retreats recorded in history. While adjusting the affairs of his department of the empire, he met Cleopatra, queen of Egypt, and from that moment became the complete slave of her caprices, extending her dominions, ruling as she dictated, and deserting his wife (Octavia, the sister of Octavius, whom he had married after the death of Fulvia), to lead a life of unexampled luxury and sensuality with his new mistress at the Egyptian capital. The Romans were enraged. Octavius sent a fleet and army against him, and defeated him in the naval battle of Actium (31), partly through Antony's fatuity in following Cleopatra when she retired from the engagement, in which she at first acted as his ally. For a time he abandoned himself again to his old excesses. In a few months Octavius again completely defeated him in Egypt. His resources were now at an end, and, rendered desperate by his failure and by a false report that Cleopatra had committed suicide, he stabbed himself, and died in her presence, having been carried to her wounded as soon as he discovered that the report of her death was untrue.

ANTRAIGUES, Emmanuel Louis Henri de Lannay, count d', a French adventurer and secret agent, born at Villeneuve-de-Berg about 1755, assassinated near London, July 22, 1812. He was a patron of science, letters, and art, figured conspicuously in aristocratic circles, where in 1788 he was called the handsome conspirator, and wrote against the nobility. After his election in 1789 as deputy to the states general he soon returned to royalist doctrines, and leaving France in 1790, was subsidized by foreign governments to intrigue against the revolution. His name became notorious in the conspiracies against Napoleon, who had him arrested in Italy in 1797, with documents incriminating Pichegru. He escaped, went to St. Petersburg, joined the orthodox Greek church, and received a pension and the office of chancellor of the Russian legation at Dresden (1803), whence he was expelled by order of Napoleon, against whom he had published a famous diatribe (*Fragment du 18^{me} livre de Polybe, trouvé sur le Mont Athos*). He next betrayed Russia by revealing to Canning the secret articles of the treaty of Tilsit, and received a large pension from the English government; but Napoleon's detectives having, as was supposed, received copies of these documents through his valet Lorenzo, the latter, fearing the consequences of his treachery, assassinated his master and his wife, and then shot himself.

ANTRIM. I. A county forming the N. E. extremity of Ireland, in the province of Ulster, bounded N. by the Atlantic ocean, E. by the North channel, S. by Belfast Lough and county Down, and W. by Lough Neagh and county Londonderry; area, 1,191 sq. m.; pop. in 1871, 419,782. The surface is hilly, and near the E. and N. E. coasts there are several considerable elevations, from which the country slopes gradually inland to the level of Lough Neagh. There are no considerable rivers except the Bann, which flows between this county and Londonderry. The seacoast is bold and rugged, formed of lofty basaltic cliffs, and presenting, between Bengore Head and the mouth of the Bann, the singular formation known as the Giant's Causeway. (See **GIANT'S CAUSEWAY**.) In the N. E. part of the county, called "the Glens," are picturesque and fertile valleys, and the scenery is varied and pleasing. Besides agriculture, the linen manufacture is the chief employment of the people; and along the coasts an extensive fishery is carried on. The principal towns are Belfast, the county town (a part of which, however, belongs to county Down), Antrim, Ballymena, Carrickfergus, Larne, and Lisburn. **II.** A market town of the preceding county, situated on the right bank of the Six-Mile Water, less than a mile from its embouchure into Lough Neagh, and 13 m. N. W. of Belfast; pop. in 1871, 2,131. It is a principal seat of the linen manufacture. The town is well built, and consists of little more than one long street, with its short cross streets. Near it are Antrim castle and Shane's castle, one of the celebrated round towers of Ireland. On June 7, 1798, a battle was fought here between the English troops and the United Irishmen, resulting in a victory for the former.

ANTRIM, a county of Michigan, in the N. W. of the main peninsula, bordering on Grand Traverse bay, Lake Michigan; area, 700 sq. m.; pop. in 1870, 1,985. There are several small lakes in the county. The productions in 1870 were 8,596 bushels of wheat, 10,605 of Indian corn, 4,270 of oats, 45,098 of potatoes, 22,920 lbs. of butter, and 16,268 of maple sugar. There were 12 school houses and 399 children attending school.

ANTWERP (Fr. *Anvers*; Span. *Ambéres*; Ger. and Flem. *Antwerpen*). **I.** A province of Belgium, bounded N. by Holland, and E., S., and W. by the Belgian provinces of Limburg, Brabant, and East Flanders; area, 1,094 sq. m.; pop. in 1869, 485,833, nearly all Roman Catholics. The province is almost an uninterrupted flat, but chiefly composed of fertile soil, excepting some barren districts in the N. and N. W. The district called the "polders," extending along the Scheldt from Antwerp to Zandvliet, originally a swamp, has been drained and converted into rich pasture and arable land. The principal rivers are the Scheldt, which borders it on the west, and its navigable tributaries, the Rupel, the Dyle, and the Great and

Little Nèthe. The province is rich in wheat, rye, barley, flax, hemp, fruit, cattle, horses, fish, honey, and tobacco, and in manufactures of cotton, lace, woollens, linens, silks, soap, spirits, refined sugar, salt, leather, and oil. The principal towns are Antwerp, Mechlin, Lierre, Turnhout, Boom, Gheel, and Zandvliet.

II. A city, capital of the preceding province, and the principal seaport of Belgium, situated on the right bank of the Scheldt, 45 m. from its mouth, and 29 m. by railway N. of Brussels, in lat. 51° 13' N., lon. 4° 24' E.; pop. in 1869, 126,668. The recent removal of the old fortifications has vastly extended the area of the city. The old citadel, long regarded as a model fortress, has been razed, and the greater part of its site was sold in 1870 to the Prussian railway contractor Strousberg for 14,000,000 francs, under the condition that about half of the space should be reserved for the construction of basins, docks, and wharfs. The rest of the ground is to serve as a site for a new railway station. A new city, with fine boulevards, squares, and promenades, has sprung up on the site of the old ramparts and bastions. The new fortifications, constructed in 1862-'5, extend over an area of nearly 20 m. The new citadel (*citadelle du nord*) commands the river and is connected with the principal old fort by a new curved line of walls. The outer circle of detached forts, each provided with about 135 guns, are linked together by a military road beyond the reach of shells from an enemy outside. About one half of the enceinte is defensible by inundations produced by cutting the dikes. The whole enceinte is expected to afford room for about 30,000 men in bomb-proof barracks. The cost of the new work is estimated at about 12,000,000 francs. Gun carriages and artillery appendages are made in the arsenal, and ammunition for ordnance and small arms in the pyrotechnic school. The magnificent dockyards constructed under the direction of Napoleon I. were demolished in 1814 in accordance with the treaty of Paris, but the two great basins were preserved and have been converted into docks, which are lined with warehouses. New dock basins (*Kattendyk*) were opened in 1860. An extensive system of canals affords facilities for inland traffic. The old part of the city retains its quaint Flemish characteristics. The Flemish language is spoken by the mass of the people and French by the cultivated classes. On the Place Verte is a conspicuous statue of Rubens, who lived and died here. Vandyke's is near the museum, and one of Teniers was erected in 1867. The cathedral of Antwerp, one of the most celebrated Gothic edifices of Europe, contains master works of Rubens and other celebrities. The churches of the Augustines, St. James, St. Anthony of Padua, and others, contain also remarkable paintings of the great masters. In the church of St. George, opened in 1853, are frescoes by Guffens and Sweerts. The works of Rubens

and Vandyke give the highest celebrity to the academy or museum of painting. The old bourse, which served as a model for the

The Cathedral of Antwerp.

London exchange, was destroyed by fire in 1858. The new bourse is near the hôtel St. Antoine. The hôtel de ville contains fine paintings. Among the other public buildings are the library and the botanical and zoölogical gardens. The city is connected by railways with all parts of the continent, has regular steam communication with English, Dutch, and German ports, and is a point of departure for emigrants to the United States. In 1840 the tonnage was about 350,000; in 1856, 900,000; and in 1871, over 2,000,000. About 7,000 vessels annually enter and leave the port. The navigation and commerce of the United States with Antwerp for 1870 comprised 50 vessels entered and 48 cleared; the inward cargoes, chiefly guano and petroleum, were estimated at \$4,528,693, and the outward at \$2,046,147. The larger portion of the Belgian import and export trade, valued in the aggregate at 5,000,000,000 francs, passes through this port.—Antwerp was a place of importance as early as the 11th century, and was at the zenith of its prosperity in the 15th and 16th, with a population estimated as high as 200,000, and a commerce extending all over the world; and the Scheldt was filled with shipping of all nations, 2,500 vessels being there at one time. Charles V., to protect himself against the citizens, added in 1567 a citadel to the original fortifications of 1540. A conflict in 1576–7 between the

local, German, and Spanish troops, resulted in the death of 10,000 persons and in the surrender of the citadel by the citizens. In 1583 the latter defeated the attempted seizure of the city by the duke of Anjou. On Aug. 17, 1585, the citadel capitulated after 13 months' siege, one of the most eventful in history, to the duke of Parma, Spanish viceroy of the Netherlands. The prosperity of the place, shaken by these vicissitudes, was almost annihilated by the closing of the navigation of the Scheldt in the middle of the 17th century. Rotterdam and Amsterdam during this period superseded Antwerp in importance, and its commerce did not begin to revive till after the acknowledgment of the freedom of the Scheldt navigation by Holland in 1795. The citadel was captured in 1746 and 1792 by the French, in 1793 by the Austrians, and in 1794 once more by the French. In 1809 Bernadotte protected the city against Lord Clatham's attempt to destroy the port and the forts. In 1814 it was defended against the English by Carnot, the French governor, and surrendered only after the conclusion of peace, May 5. After the union of Belgium with Holland (1815) Antwerp carried on an extensive trade with Java, which has since been diverted to Dutch ports. In 1830, during the Belgian revolution, the city was bombarded from the citadel by the Dutch general Classé, who was finally forced to surrender his stronghold Dec. 23, 1832, after a siege by a French army of 50,000 men under Marshal Gérard. This ended the contest with Holland, and on Dec. 30, 1832, the citadel, almost wholly destroyed by the bombardment, was occupied by the Belgian troops, since which period the city has become the great commercial emporium and military stronghold of Belgium. The abolition by settlement in 1863 of the Belgian Scheldt dues had a happy effect upon the prosperity of Antwerp. In September, 1871, a great part of the city was destroyed by fire, but rapidly rebuilt.—The remarkable former artistic achievements of Antwerp are described in Schnaase's *Niederländische Briefe* (Stuttgart, 1834); and among the more recent historical works relating to the city is *L'Histoire de la ville d'Anvers*, by Gens (Antwerp, 1861).

ANUBIS (Eg. *Anepu*), one of the principal Egyptian deities of the second cycle. He was represented either as a dog or a man with a dog's or a jackal's head. Sometimes he wore a double crown. A white and yellow cock was sacrificed to him. The town of Cynopolis, in

Anubis.

the lower Thebais, built in his honor, was the special seat of his worship. He is said to have represented the horizon. The name signifies gilded, and his images were either of solid gold or gilt. He was supposed to be the illegitimate son of Osiris by Nephthys, and was the attendant and guardian of Osiris and Isis. When Osiris was murdered by Typhon, Anubis helped Isis to find his body. He accompanied the souls of the deceased to their place of judgment, and weighed their actions before the tribunal of Osiris. In the Greek mythology he was identified with Hermes.

ANVIL, an iron block with a smooth face on which smiths hammer and shape their work. The smallest anvils, called bickerns, are mostly made of steel. The largest, used with tilt, trip, or steam hammers, are of cast iron, and of a very uniform and simple shape. They are truncated quadrangular pyramids, placed with the small end up, the large resting upon a block of wood fixed in the ground. The middle-sized anvils, on which the forging is performed with sledge hammers, are made of cast or wrought iron. Formerly extra good anvils were made of wrought iron covered with steel, the fibres of which were placed vertically. To do this the bars of steel were cut in pieces about an inch long, which were placed standing side by side, bound by a wire, and welded into a steel plate, which was itself welded to the anvil. The heat necessary for welding very often altered the steel, which was brought back to its original state by the anvil being warmed for a few hours in a box full of cement. It was afterward hardened by pouring a stream of water upon the steel face till the whole block was cooled. The best anvils made in the United States are of cast iron covered with steel; they possess most of the advantages above described, and are comparatively cheap. The covering of steel is placed at the bottom of a mould, and cast iron is poured upon it. Some makers place a core in the mould so as to leave a deep recess nearly reaching the steel covering in the centre of the anvil. The air penetrates into this recess, and the metal is cooled more uniformly.

ANVILLE, Jean Baptiste Bourguignon d', a French geographer, born at Paris in 1697, died there in 1782. At the age of 15 he published a map of ancient Greece. In his 22d year he was appointed royal geographer. He published 211 maps and plans, and 78 *mémoires*. One of his best maps is that of ancient Egypt. His *Orbis Veteribus Notus* and his *Orbis Romanus* have become standard guides for students of ancient history. His "General Atlas," his *Atlas Antiquus Major*, and his maps of Gaul, Italy, and Greece during the middle ages, are celebrated. In 1779 the French government purchased for the royal library his large collection, which consisted of 10,500 maps.

AORTA (Gr. ἀορτή, air vessel), the largest artery in the body. The aorta and arteries were first named air vessels by Greek anatomists,

because until the time of Galen they were supposed to contain air instead of blood. The aorta arises from the left ventricle of the heart, ascends a short distance toward the neck, and then curves obliquely backward and toward the left in a semicircular bend, at the level of the second dorsal vertebra, forming the "arch of the aorta." It then passes downward through the posterior part of the chest and abdomen, to the point where it divides into the two common iliac arteries, which are each in turn divided on either side into an internal branch, ramifying into the lower regions of the trunk, and an external branch, descending to the lower limbs. The carotids arise from the arch of the aorta to supply the head and face, and the subclavian arteries derive from the same arch, to supply the different regions of the neck and the upper limbs. Numerous large arteries arise from the aorta or main trunk as it descends from the upper to the lower portions of the trunk; and these divide again into innumerable branches as they ramify minutely and extensively within the body.

AOSTA (anc. *Augusta Prætoria*), a town of Piedmont, in the province and 49 m. N. N. W. of Turin, on the Dora-Baltea, at the foot of the Great St. Bernard, and the southern termination of the Alpine pass of that name; pop. 6,000. It contains many Roman remains, and was the birthplace of Anselm, archbishop of Canterbury, and the scene of the labors of St. Bernard, founder of the hospice bearing his name, who held the archiepiscopacy of Aosta. The valley in which it stands is famous for its immense pine forests, mines of copper, lead, and iron, and marble quarries. Cretinism and goitre prevail among its inhabitants. The third son of the king of Italy (Amadeus, late king of Spain) derives his title of duke of Aosta from this town, which has been greatly improved during the last 15 years.

APACHES, a fierce nomadic nation of the great Athabasean family, roaming over portions of Texas, New Mexico, and Arizona in the United States, and Sonora, Chihuahua, and Durango in Mexico. The Apaches proper have only temporary war chiefs, and do not cultivate the soil, while the Lipans, a tribe of the same race and language, have their regular chiefs whom they obey; and the Navajos, another tribe of the same language, cultivate the ground and manufacture excellent blankets. The Apaches comprise the Jicarillas, in the Sacramento mountains; the Gila Apaches, on the San Francisco; the Tonto Apaches, on the Sierra del Mogoyen, their impregnable position; the Mimbrenos, in the Sierra de los Mimbres; the Copper Mine Apaches, on the Rio Grande, and for part of each year in Chihuahua and Sonora; the Mescalero Apaches, ranging from the Sierra de Guadalupe to that of San Andrés and west to the Rio Grande; with some smaller bands. As the Spanish settlements advanced the Apaches became the scourge of the frontier, repelling all attempts to civilize and convert them.

No mission was ever established among them, and they drew to them tribes who shook off the Spanish yoke. A document on Sonora in 1762 estimates the mining towns, stations, and missions depopulated by the Apache inroads into that province at 174. Since the annexation of the Apache territory to the United States the tribe have given great trouble, especially those under Mangas Colorado, who for 50 years led very large bands to war, till he was finally captured and killed while attempting to escape, in 1863. Within a few years an effort has been made by the government to gather the Apaches upon reservations under the superintendency of New Mexico, and there feed them. The sum of \$125,000 was appropriated for the support of these Indians in 1871, and the experiment of confining them to particular localities is believed to have been attended with some success. The commissioner estimates that in the event of a complete adoption of the plan, it will require an expenditure of \$25,000 a month, or \$300,000 a year. The plan of establishing the Apaches on reservations and feeding them for a time was much opposed by the people on the frontiers, Mexican and American, who had long been victims of their ravages. This led to a massacre at Camp Grant, Arizona, April 30, 1871, of more than 100 Apaches who were actually prisoners in the hands of the United States troops. Cochise, the great Apache chief, however, submitted, visited Washington, and seemed well disposed. The numbers of the Apaches proper in the United States are variously estimated. Mr. Bartlett thought Schoolcraft's statistics too high. By the Indian commissioner in 1871 they were estimated at 7,500, though Cremony in 1868, from eight years' stay in their country, thinks their number at least 25,000.—The language of the Apaches abounds in guttural, hissing, and indistinct intonations. Mr. Bartlett in his "Report on the Boundary Commission," and others, give vocabularies that establish its connection with the Athabaskan family. Their lodges are built of light boughs and twigs. The captain of the band wears a kind of helmet made of buckskin, ornamented with a feather. Their arrows are very long, usually pointed with iron. All are mounted on small ponies, capable of great endurance. The Spanish bit, or simply a cord of hair passed between the jaws, forms their bridle. Panniers for holding provisions are generally carried on the horses of the women. The shells of the pearl oyster, and a rough wooden image, are the favorite ornaments of both sexes. Their feet are protected by high moccasins of buckskin, and the smallness of the foot resulting from this has always distinguished their trail from that of other Indians. Their principal articles of clothing, formerly of deerskin, are now made of coarse cotton cloth. Many of them dress in the breech-cloth only, but they are beginning to wear the blanket

and straw hat. The women wear a short petticoat, with their hair loose. Those in mourning for husbands killed in battle cut their hair short. The younger children go almost entirely naked. Those under the age of two years are carried in a kind of osier basket by the mother, in which the child is fastened in a standing posture. When on horseback, the basket is fastened to the saddle. They do not scalp their enemies. They are fond of card-playing and of smoking, and when idle are given to a monotonous kind of singing. When fighting they keep their horses in rapid motion, and are never at rest in the saddle. In their religious ideas they seem to favor the belief in one God; and Montezuma, or his spirit, is blended in their minds with a certain crude religious aspiration. They have a superstitious reverence for the eagle and owl, and for all perfectly white birds. They equally respect the bear, and refuse to kill it or to partake of the flesh. To the hog they have the same repugnance as the Jews and other Asiatic tribes.

APE. a quadrumanous animal of the class mammalia, nearly approaching the human race in anatomical structure. A common distinction between the monkey, baboon, and ape is, that the first has a long and prehensile tail, the second a short one, and the third none at all. According to the modern zoological definition, however, the genus ape, or *pithecus*, comprises those quadrumanous mammals which have the teeth of the same number and form as in man, and which possess neither tails nor cheek pouches. This definition, while it excludes certain tailless baboons and monkeys, comprehends the three sub-genera of oranges, chimpanzees, and gibbons. Their arms almost touch the ground when they stand erect on their hind legs; but the legs are scarcely a third part of the entire height. The legs are not on the same line with the thighs; the knees are turned outward, and the soles of the feet turn inward, so as to be opposed to one another. The apes are thus enabled to grasp the trunks of trees with much greater force than if their members were constructed like man's. The fingers and toes are long, flexible, and deeply separated from one another; and the thumb, or anterior finger, is completely opposite to the other four, as well on the hind as on the fore limb. Thus their hands and feet are equally well formed for grasping, and can be used indiscriminately. Hence, apes are neither two-legged and two-handed, like the human race, nor four-footed, like quadrupeds, but four-handed (quadrumanous). When they walk erect, which they rarely do without the aid of a staff or of their forearms, owing to the oblique articulation of the lower extremities, they rest only on the outer edge of the feet. This gives them a tottering and uncertain motion, to remedy which they place the fists of their long arms on the ground, and move in the attitude and at the pace of a lame man going on crutches. Consequently, while

on the ground, they are slow, inert, and helpless animals, although in their native forests, passing from bough to bough and from tree to tree, they are the most agile of all creatures.—The character and habits of the great apes in a state of nature are little understood. Notwithstanding the gentleness and docility of those brought young from their native climates, there is reason to believe that in their native wilds they become as they grow old fierce, dangerous, and perhaps even carnivorous; for, although the number of their teeth and the formation of the molars and incisors precisely resemble those of the human being, the canines are developed in the same relative proportion as in the carnivora, so much so that the tusks of a full-grown orang-outang are fully equal to those of a lion. In confinement, however, they are almost wholly free from the mischievous and petulant curiosity and violent fits of passion which characterize the smaller monkeys; are deliberate in their actions, circumspect, intelligent, and susceptible of a high degree of attachment to those who take care of them, or with whom they consort. They have two singular points of resemblance to man in their habits, which are worthy to be contrasted with the structural dissimilarities which have been insisted on above: 1. They do not repose, like the other monkeys, squatting on their hams, but stretch themselves on their sides, like human beings, and support their heads on their hands, or find some natural substitute for a pillow. 2. Alone of animals, they use other means of defence or attack than their own natural means, strength, and weapons, readily betaking themselves to the use of stones and clubs, which they wield with considerable dexterity, either hurling them as missiles, or using them hand to hand. In their mental powers, or intelligence, the apes in nowise approach the dog, the elephant, or the horse, although their natural facility of imitating human action has obtained for them the credit of approaching nearly to human comprehension.—See CHIMPANZEE, GIBBON, GORILLA, and ORANG-OUTANG.

APELDOORN, a town of Holland, province of Gelderland, 15 m. N. of Arnhem; pop. in 1868, 12,087. In 1871 it had 42 manufactories of papier maché. Near it is the royal castle of Loo.

APELLES, the most celebrated of Greek painters, born, according to Pliny and Ovid, in the island of Cos; according to Suidas, at Colophon. Strabo and Lucian call him an Ephesian, but he appears to have been such only by adoption, and to have studied at Ephesus. His instructors were Ephorus the Ephesian, Pamphilus of Amphipolis, Melanthus, and, according to Athenæus, Arceilaus. The masterpiece of Apelles was his Venus Anadyomene, or "Venus Rising from the Sea," the model for which is believed to have been either Phryne or Campaspe, one of the royal mistresses whom Alexander the Great resigned to the painter.

This painting was ultimately placed by Augustus in the temple of Julius Cæsar, where it was gradually destroyed by age. It is said that Alexander, whom, according to some, Apelles accompanied in his expedition to Asia, would allow no one but Apelles to paint his portrait; and one of his paintings representing Alexander holding a thunderbolt was sold for a sum equal to about \$200,000. He was accustomed, when he had completed a piece, to expose it to the view of passers-by, and to hide himself behind it in order to hear the remarks of the spectators. On one of these occasions a shoemaker censured the painter for having given one of the slippers of a figure a less number of ties than it ought to have had. The next day the shoemaker, emboldened by the success of his previous criticism, began to find fault with a leg, when Apelles indignantly put forth his head and desired him to confine his criticism to the slipper. Hence arose the expression *Ne sutor ultra crepidam*, "Let not the cobbler go beyond his last."

APELT, Ernst Friedrich, a German metaphysician, born at Reichenau, March 3, 1812, died in Jena, Oct. 27, 1859. He was a professor at Jena, and a disciple of Jacob Friedrich Fries, whose theories he supported in various works, especially in the 2d volume of his *Epochen der Geschichte der Menschheit* (Jena, 1845). He edited Fries's posthumous *Politik, oder philosophische Staatslehre* (1848), and wrote *Theorie der Induction* (Leipsic, 1854), *Metaphysik* (1857), and *Die Reformation der Sternkunde und Religionsphilosophie* (1860). His philosophical method has been described as combining the theories of Kant with the ideas of Jacobi, and is fully explained in Kuno Fischer's *Die beiden Kant'schen Schulen in Jena* (Stuttgart, 1862).

APENNINES, a chain of mountains in Italy, extending, with but trifling intervals between its principal groups, through the entire length of the Italian peninsula, from the Maritime Alps to the straits of Messina, a distance of 800 m. Through the greater part of its extent the chain is about equally distant from the Adriatic and the Mediterranean. No part of it is above the limit of perpetual snow; its highest peak, Monte Corno, near Aquila, rises only 9,542 ft. above the sea; while the average height of the range does not exceed 4,200 ft. To the height of 3,000 ft. the Apennines are generally covered with forests; above this their sides are bare and rugged, and their summits rough and broken, not rising into symmetrical peaks or needles, like those of the Alps.—The range is divided by the best geographers into five portions, the Ligurian, Tuscan, Roman, Neapolitan, and Calabrian Apennines. These are in turn divided into smaller groups. 1. The Ligurian Apennines, which are not in reality separated at their western extremity from the Maritime Alps, are generally considered as beginning near the source of the Bormida, a short distance W. of Savona, though

the point of division between them and the Alps is differently assumed by different geographers. They run N. E. as far as the pass of the Bocchetta, N. of Genoa, and then S. E., following the trend of the coast, and joining the Tuscan Apennines a short distance S. of Monte Pellegriano. Their entire length is about 130 m. The breadth of the chain varies greatly; in the north its spurs extend nearly to the Po. West of the Bocchetta pass the summits are low, seldom rising more than 2,000 ft.; but beyond this to the eastward the height of the range increases. Its principal peaks, all between 5,000 and 6,000 ft. high, are Monte Antola, N. E. of Genoa; Monte Penna, near Chiavari; Monte Gottaro, W. of Pontremoli; and Monte Pellegrino, N. of Castelnuovo. Several important roads cross the chain; one (with a railway), at the pass of the Bocchetta, is the means of communication between Genoa and the towns N. of the mountains; a second, from Parma to Pontremoli, crosses by the pass of La Cisa; another, at the western extremity of the range, leads from Millesimo to Savona; while smaller passes are found at different points. The pass of the Bocchetta is famed for the grandeur of its scenery; and the whole aspect of the Ligurian Apennines is more picturesque than that of any other portion of the great chain. 2. The Tuscan Apennines begin with Monte Cimone, and, extending S. E. for about 80 m., end with the Alpe della Luna, near the pass through which runs the road from the valley of the Tiber to Urbino. Monte Cimone (6,973 feet) is the highest peak. To this portion of the chain belong, besides some less important detached groups, the Alpi Appuane, which rise to a height of 5,800 ft. (the Pizzo d'Uccello being their highest summit), run nearly parallel with the main range, and extend to the valley of the Arno. In these mountains is found the celebrated marble of Carrara; the principal quarries are in the sides of Monte Sauro, near the town of Carrara. 3. The Roman or Central Apennines extend S. E. a distance of about 150 m., and include, especially in that portion best known as the mountains of the Abruzzi, all the highest peaks of the whole range. Here lies the great group of the Gran Sasso d'Italia, whose summit, Monte Corno, or Monte Cavallo, is the highest point of the Apennines, 9,542 ft. above the sea. The range is broader here than at any other point; the mountain groups of the Abruzzi form a large square, and throw out spurs in all directions. The lake of Celano lies among the southern mountains of this chain, at an elevation of nearly 2,200 ft. The Roman Apennines are traversed by many passes, and surround fertile upland valleys and elevated plains. Besides Monte Corno, the principal peaks are Monte Amaro, in the detached group of the Majella, which rises to the height of nearly 9,000 ft.; Monte Vellino, 8,183 ft.; Monte Vittore, 7,398 ft.; Monte Sibilla, 7,212 ft.; and Il Terminillo Grande, 7,034 ft.

4. The Neapolitan Apennines begin near the southern limits of the Abruzzi, and extend in a broad chain, with many considerable offshoots, to Monte Vulture, near which they begin to divide into two branches. One of these runs S. E. as far as the gulf of Taranto. Beyond the river Ofanto it dwindles to a range of low hills, and finally almost disappears in the district of Otranto. The other branch takes a southerly direction, to the pass of Lagonegro. To the eastward of the Neapolitan range, but so widely separated from it as to properly form a distinct ridge, lies Monte Gargano (5,450 ft.), extending into the Adriatic, and forming the rugged promontory N. of the gulf of Manfredonia. The highest peak of the chain is Monte Miletto, 6,744 ft.; but the average height of this division is less than that of the others. 5. The Calabrian Apennines, beginning at the pass of Lagonegro, fill the peninsula of Calabria, and terminate in the mountain promontory of Aspromonte, the highest summit of which rises 4,500 ft. above the sea. A singular and almost complete break is made in them by a deep valley, which runs from the gulf of Santa Eufemia to the gulf of Squillace, and divides the chain into two distinct groups. The Calabrian Apennines have no very lofty or noteworthy peaks, but their scenery is rugged and picturesque. They are granitic, and differ in their geological features so entirely from the rest of the Italian chain that most geographers, while applying the name Apennines to them in compliance with general usage, really class them as a separate system.—West of the Apennines, and filling much of the country between them and the Mediterranean, lies a separate system of lower mountains, different from them both in appearance and geological formation. These are called the Sub-Apennines. They include many mountains of volcanic origin, and are the result, according to the best authorities, of a much later convulsion than that which undoubtedly threw up the more massive pile of the main range. 1. The Tuscan Sub-Apennines occupy the space between the Arno and the Tiber, reaching their greatest height in the S. E. part of this tract. They surround a great part of the plain of the Arno. Among their best known groups are the Cimian hills. 2. The Roman Sub-Apennines are almost all of volcanic origin; they extend from the Tiber, and surround the principal part of the Campagna di Roma. The Alban hills are a part of this division, which, running southward along the coast, ends at the promontory of Gaeta. 3. The Neapolitan Sub-Apennines include in their southern portion the volcanic group of which Mt. Vesuvius is the great centre, and extend to the Punta della Campanella.—The mountains of Sicily undoubtedly form, with few exceptions, a part of the system of the Apennines. (See SICILY.)—Limestone, chalk, and sandstone are the basis of the northern portion of the Apennines, and of most parts of the main chain through the entire peninsula;

tertiary formations containing abundant fossils distinguish many of the offshoots, and, as has been already noticed, groups of purely volcanic mountains appear in many places among the Sub-Apenines, and even approach the main range, to the system of which they in no way belong. This volcanic formation is found only on the western side of the chain.—For the vegetation of the Apenines, the rivers flowing from their sides, the methods of cultivation employed on their fertile lower slopes, and the people inhabiting the mountain country, see ABRUZZO, CALABRIA, and ITALY.

APENRADE, a seaport town in the Prussian province of Schleswig, situated on the Baltic, 20 m. N. of Flensburg; pop. in 1871, 5,932. On March 30, 1848, there was here an encounter between the Prussians under Wrangel and the Danes. Near the town is the castle of Brundlund.

APHIS, the plant louse, or puceron, a genus of insects included in the order *homoptera*. The number of species is very large; 326 are described in Francis Walker's list of specimens of homopterous insects in the collection of the British museum. Almost every sort of plant furnishes a living to a different kind of aphid. The attacks of these insects are often ruinous to certain crops. The *A. roseæ* is most destructive to the rose tree, on which it is constantly found. Apple trees and pear trees are attacked by a species of aphid which injures their fruit. Cabbage and turnip crops are sometimes destroyed by swarms of the *A. brassicæ*. Their attacks on all plants seem to be regulated by the health of the plant and the peculiarities of the season. If atmospheric conditions render the plant unhealthy, then the aphid appears; if these cease, the aphid disappears; and one crop of plants may be attacked several times in the same year. Most species of this insect are green; but a dark species, the bean dolphin, or *A. fabæ*, attacks the bean, whole acres of the plant being suddenly covered by these black insects. They have, however, many destructive foes. The larvæ of the lady-bird (*coccinellidæ*), the *syrphus* or bee-like fly, the *chrysopa* or lacewing, and several species of *ichneumonidæ*, pursue and eat them very greedily. Tobacco is the principal remedy against destructive swarms of the aphid. In conservatories, or where plants can be placed under cover of any kind, they may be easily exposed to clouds of tobacco smoke, and that is the simplest way of destroying the aphid; but in the open air, where the fumes of tobacco easily disperse, the best way is to apply the tobacco in water. The affected parts may be syringed with the infusion of tobacco, and after the effect is produced, the plant may be washed by the rain or with pure water.—These insects have a soft, roundish body, a small head, complete and half-globular eyes, antennæ of from 6 to 11 joints, longer than the head and often hairy. The beak has its origin from the lower part of the head, between the fore legs, and in the act of sucking

is held nearly perpendicular. The wings, when developed, are 4 in number. The legs are very long and slight. Near the extremity of the abdomen above, most kinds of aphids are provided with a pair of tubular horn-like processes, through which they eject a sweet, thick fluid, commonly called honey-dew, of which ants and many other insects are very fond.—At the end of autumn many of the species, such as the *A. quercus* and the *A. rosæ*, of both sexes, are numerous, some winged, and some without wings. While some can fly to a distance, others, without wings, are restricted to the neighborhood of their native plant. As soon as she has paired, the mother aphid deposits her eggs or larvæ in a place fit for passing the winter, different places being selected by different species. Some prefer the oak, and leave their eggs on some waving bough high in the air; others in the crevices of the bark, or in a subterraneous receptacle. Bonnet supposes that the aphides are always viviparous, and never lay eggs; what are commonly called eggs, produced in the autumn, being a sort of cocoon, containing the young aphid enclosed in an envelope. This, however, is not universally admitted. The parents die after disposing of their eggs or cocoons, and these remain torpid during the winter. All the aphides which appear in spring are females, which are endowed with a most wonderful spontaneous fecundity, no pairing being possible, as no males appear till autumn. Latreille states that one female during the summer months will produce 25 daily, each of which will in turn do the same, and so on for several generations in a single season. Réaumur calculated that one aphid may be the progenitor of about 6,000,000,000 descendants in its own lifetime. The *A. lanigera* produces each year, says Prof. Owen in his "Lectures on Comparative Anatomy," 10 viviparous broods, and one which is oviparous; and each generation averages 100 individuals. The progression is 1, 100, 10,000, 1,000,000, 100,000,000, 10,000,000,000, 1,000,000,000,000, 100,000,000,000,000, 10,000,000,000,000,000, 1,000,000,000,000,000,000, for the 10 viviparous broods; and by adding the oviparous generation, the result is 30 times greater. The female aphides thus produced are considered as larvæ, presenting a more developed condition than the larvæ of coleoptera and lepidoptera. The compound eyes are completely developed; the antennæ have attained their perfect shape and proportions, the 6 thoracic legs their full size and power. The only subsequent change of these fertile larvæ is an additional size and the manifestation of the organs of reproduction. In the last generation, which is the 7th, the 9th, or the 11th, according to the species of aphid, the spontaneous power of reproducing their species is totally lost; wings are developed, and winged male insects now make their appearance. The females of the present generation are the winged insects which produce eggs and deposit them where they may be hatched by the sun in times

of blight. The number of aphides which appear in spring must, of course, depend on the number of eggs laid in the preceding autumn; but countless swarms of them being ushered into life at the same time has led to the notion that they are generated by the atmosphere.

APHRODITE. See VENUS.

APICIUS, the name of three noted Roman epicures. **I.** Lived in the earlier part of the 1st century B. C. He spent much of his time at intervals in Latium, on account of its excellent lobsters, but having heard that the African lobsters were larger, set sail for that continent. Several fishermen came off to his vessel with the finest; but seeing that they were inferior to those of Minturnæ, he ordered the pilot to steer for Italy. He is said to have procured the banishment of Rutilius Rufus in 92. **II.** Marcus Gabius, who lived in the time of Augustus and Tiberius, established a school where the art of good cooking was taught. In the cultivation of his own appetite and that of his scholars, he had expended more than \$3,000,000, when he settled up his accounts, and perceiving that but about \$300,000 remained, concluded that he could not live as he wished upon that sum, and poisoned himself. He invented several sauces and cakes which long bore his name. Apion, the grammarian, made his life and labors the basis of a volume; and all cooks for centuries belonged to the Apician or anti-Apician faction. **III.** A contemporary of Trajan, who taught the world how to pickle oysters.—A treatise, *De Re Culinaria*, or *De Obsoniis et Condimentis*, &c., bearing the name of Cælius Apicius, by an unknown writer (probably a Cælius who added to his own the famous name of Apicius), is the most ancient cookery book in the world.

APIS (Egyp. *Ἰαπί*, a name closely resembling that of the Nile), a bull worshipped by the Egyptians. In their mythology the soul of Osiris, murdered by the evil spirit Typhon, migrated into this bull. It was therefore the symbol of creative productivity and fertility. The calf was born from a cow made pregnant by a ray of the sun and one of the moon. It must be black, with a white triangular or square spot on the forehead, a vulture or an eagle on the back, various other mystical signs on various parts of the body, and a scarabæus under the tongue. Its principal worship was in Memphis, in the temple of Phthah (Hephæstus, Vulcan, or fire). When such a calf was found, the priest transported him in a chariot with great pomp to Heliopolis, where he was kept in a temple accessible to the worship of the people for 40 days. After that lapse of time no one could approach him, and he was transported to Memphis, where he had his own temple, with chapels and courts for exercise, and his own priests. The lifetime of Apis was 25 years, in harmony with one of the theologico-astronomical cycles of the Egyptians. After the death of one and before the finding of another Apis, the whole land was in mourn-

ing. Apis in heaven was placed in the constellation of Taurus.

APLANATIC LENS (Gr. *ἀ* privative and *πλανητικός*, wandering), a lens made in such a way as to correct the spherical aberration. When rays come from a great distance, this may be done by making the curve of a lens parabolic in place of spherical, and in telescopes it is accomplished by careful repolishing by hand and testing. For microscopic and photographic lenses, however, a system of two or even more double achromatic lenses is employed, of which the curves are such that all the rays emitted from one point come to a single focus in a corresponding point. Such a microscopic lens is said to consist of an aplanatic system of lenses, and perfection in this respect is the great problem, now being solved by manufacturers of microscopes and photographic cameras.

APOCALYPSE (Gr. *ἀποκάλυψις*, unveiling), or **Revelation of St. John**, the name of the last book of the New Testament. The church at an early period appears to have ascribed the authorship of the book to John the evangelist. Papias and Melito of Sardis, according to the testimony of Eusebius, regarded the Apocalypse as inspired. Justin Martyr and Irenæus expressly quote the Apocalypse as the work of the apostle John; and the third council at Carthage, in 397, admitted it into its list of canonical books. On the other hand, Dionysius, bishop of Alexandria, testifies that some church writers before him repudiated the Apocalypse as a forgery of Cerinthus; and he himself undertakes to prove that it was not the work of the apostle John, but of some other John who lived in Asia. That this opinion was shared by other prominent men of the church may be inferred from the fact that the Apocalypse is absent from the ancient Peshito version. Jerome moreover states that the Greek church felt with regard to the Apocalypse a doubt similar to that entertained by the Latins with regard to the Epistle to the Hebrews. The rejection of the canonical and apostolical character of the book was chiefly prompted by opposition to chiliasm; and when the interest in the chiliastic controversies declined, the church generally recognized the Apocalypse as a work of the apostle John. In modern times the question of the apostolic origin of the book was revived by Semler, and many of the prominent exegetical writers of the Protestant churches (in particular De Wette, Ewald, Lücke, and Baur) undertook to prove that the Apocalypse and the Gospel of John could not possibly have been written by the same author. While, however, most of these writers deny that it was written by the apostle John, Baur, Hilgenfeld, and other critics of the Tübingen school, ascribe the Apocalypse to him, but not the fourth Gospel. Among those who have recently undertaken to prove that neither the fourth Gospel nor the Apocalypse was written by St. John, Th. Keim (*Geschichte Jesu von Nazara*, vol. i., 1867) and

Scholten (*De Apostel Johannes in Klein-Azië*, Leyden, 1871) are the most prominent. The Johannan origin of both the Apocalypse and the fourth Gospel was, on the other hand, vindicated against the critical schools by Hengstenberg, Hase, Godet, and in particular by Niermeyer (*Verhandeling over de Eehtheid der Johannische Schriften*, the Hague, 1852).—No book of the New Testament has received so many different interpretations. Two principal classes of expositors may be distinguished, the historical or continuous and the preterist. According to the opinion of the former, which is shared by nearly the entire ancient church, the Apocalypse is a progressive representation of the entire history of the church and the world. Sir Isaac Newton, Bengel, E. B. Elliott, Wordsworth, Hengstenberg, Ebrard, and Alford are prominent representatives of this class. Writers of this school have found in the Apocalyptic visions prophetic references to nearly every great event of the Christian era, such as the migration of nations, the reformation, the pope, the French revolution, and Napoleon; and the calculations of the millennium have led to varying results, and in some instances even to the establishment of particular sects. The date of the Apocalypse is given by these writers as A. D. 95–97. The preterist mode of interpretation, according to which the Apocalypse has been almost or quite fulfilled in the time which has passed since it was written, and refers principally to the triumph of Christianity over Judaism and paganism, found able advocates in Grotius, Bossuet, and Calmet, and since Herder and Eichhorn has become the exclusive interpretation of all the liberal Protestant schools of theologians. Among the recent champions of this school, Ewald, Lücke, Bleek, Stuart, Lee, and Maurice are best known. According to their view, the seven heads are seven emperors. As Galba was accounted as the sixth of the emperors, the book is supposed to have been written during his reign (in 68). The fifth, who will return as the eighth, is Nero, who at that time was believed not to be dead, but to have retired to Parthia, whence he would return. In the symbolical number 666 these writers commonly find the words "Neron Kaiser," written in Hebrew letters. Some writers, chiefly English, believe that, with the exception of the first three chapters, the book refers wholly or principally to events which are yet to come. Swedenborg regards the Apocalypse as a peculiar revelation of divine truth, the book of all books which is least encumbered by literal references to mundane things, and most remarkable for the completeness with which it contains the heavenly word.

APOCRYPHA (Gr. ἀπόκρυφος, concealed), hidden or unpublished books. This term is variously applied in the Roman Catholic and Protestant churches. The Roman Catholic church gives the name Apocrypha to those books to which a reception into the canon of the books of the Old Testament was refused.

Protestant theology generally designates these books by the name *pseudepigrapha*, and calls Apocrypha those books the inspired character of which was long a subject of dispute in the church, and which were finally declared by the council of Trent to be a part of the canon. They are not contained in the Hebrew canon of the Old Testament; but as the Septuagint embraced them, they are frequently quoted by early church writers as sacred books, were expressly received into the Christian canon by a synod of African bishops held at Hippo in 393, and were thereafter generally accepted as canonical books by the Latin church. By the Catholics these books are called deutero-canonical or antilegomena. The following books are included in this class: 1 Esdras, 2 Esdras, Tobit, Judith, Esther x. 4–xvi., Wisdom, Ecclesiasticus, Baruch, Song of the Three Holy Children, History of Susanna, Bel and the Dragon, Prayer of Manasses, 1 and 2 Maccabees. The Protestant churches continued to print the apocryphal or deuteronomic books of the Old Testament in their various editions of the Bible until about 1821, when discussions arose in the British and foreign Bible society which resulted in 1826 in a resolution that that society should no longer circulate the apocryphal books. German Protestants are divided on the subject; some theologians, as Ebrard and Keerl, declaring against the reception of the Apocrypha into the Protestant Bibles, but others, including Hengstenberg and Stier, in favor of it. The Greek church, at the synod held in Jerusalem in 1672, recognized the Apocrypha as inspired books.—That class of books to which the Roman Catholic church exclusively applies the name of apocryphal is very numerous. The most important among those relating to the Old Testament are the third and fourth books of Esdras, and in particular the book of Enoch, which has only been preserved in an Ethiopic translation (published for the first time in 1838 by Laurence). The apocryphal books of the New Testament comprise a number of spurious gospels, acts, epistles, and apocalypses, many of which were written by heretics in the interest of their sects. A complete collection of the apocryphal literature of the New Testament was begun by Thilo (*Codex Apocryphus Novi Testamenti*, vcl. i., Leipsic, 1832, containing nine apocryphal gospels). After the death of Thilo the work was continued by Tischendorf, who published in succession the Apocryphal Acts (*Acta Apocrypha*, Leipsic, 1852), a new collection of Apocryphal Gospels (*Evangelia Apocrypha*, 1853), and the Apocryphal Apocalypses (*Apocalypses Apocryphæ*, 1866). An English translation of part of them by William Hone was published in London in 1820.—See "Contributions to the Apocryphal Literature of the New Testament," by W. Wright, and "Apocryphal Acts of the Apostles," edited from Syriac MSS., with an English translation, by the same author (2 vols., London, 1871).

APOLDA, a town in the grand duchy of Saxe-Weimar, on the Thuringia railway, about 12 m. E. N. E. of Weimar: pop. in 1867, 8,882. It is remarkable for its manufacture of hosiery, which has been developed chiefly within the last ten years. Upward of 1,200 looms are in operation (1872), employing 11,000 persons. Steam power is used in the two principal establishments. There are also iron and bell founderies. There is a mineral spring, discovered in the 18th century. The castle near the town and the adjoining domain belong to the university of Jena.

APOLLINARIANS, an heretical sect, founded about 362 by Apollinaris, bishop of Laodicea, who, in his zeal against the Arians, sought to impress the following modifications on the Nicene creed: 1. That since two perfect beings cannot coalesce in one person without the production of a monster, therefore in the nature of Christ is not found the union of perfect God with perfect man. 2. That there is no human *voûs* or rational soul in Christ, the divine, or perfect God, standing in place of it. 3. That there is but one nature in Christ, and that has both a divine and human side, and the connection between them is so organic that they may each be regarded as vested with the attributes of the other. Apollinaris was censured by the councils of Alexandria and Constantinople, and Athanasius appeared as his antagonist. He died about 390. His doctrine is one of the steps in that great movement which springs out of the discussion of the dual nature of Christ, and which next reappeared in Monophysitism, into which many of the followers of Apollinaris naturally fell, while others returned to the communion of the church.

APOLLO, one of the principal gods of Grecian mythology, called also Phœbus, and in Homer and Hesiod generally designated as Phœbus Apollo. He was the son of Jupiter and Latona, and twin brother of Diana. Homer and Hesiod give no details about his birth; but later writers relate that Juno had put under ban all lands which should harbor Latona, who was then pregnant. Delos was an uninhabited rock in the Ægean, just risen above the surface of the sea. There Latona, after nine days' labor, brought forth Apollo and his sister. The earlier mythology of the Greeks, as reflected chiefly in Homer, represents Apollo as an archer who inflicts vengeance with his arrows; as a god of song and stringed instruments, in which character he is said to have invented the phorminx; as a revealer of the future, a function which he exercised especially at the temple of Delphi; and as a god of flocks, in which capacity he kept the herds of King Admetus. In the later poets he is the same as the god Helios, or the sun, but in the earlier Phœbus Apollo and Helios are quite distinct. With the advent of the lyrical poets Apollo becomes a patron of the healing art. In this aspect he is the father of Æsculapius. He was the president and protector of the muses. He is usually

represented in the prime of youth and manly beauty, with long hair, his brows bound with the sacred bay tree, and bearing the lyre or the bow. The most celebrated places where Apollo was worshipped were Delphi and Abœ in Phœcis, Ismenium near Thebes, Delos, Tenedos, Didyma near Miletus, Patara in Cilicia, and Clarus near Colophon. The hawk, the raven, the swan, and the grasshopper were his favorite animals. Apollo was the peculiar god of the Dorians. He had musical contests with Marsyas and Pan. According to Herodotus, the Egyptian synonyme of Phœbus Apollo is Horus. The Romans received him from the Greeks. We first hear of his worship at Rome in 430 B. C., when a temple was raised to him for the purpose of averting a plague. During the second Punic war, in 212, the *ludi Apollinares* were established at Rome. Every centenary anniversary of the *ludi*, they celebrated in his honor the *ludi sæculares*. Horace wrote the *Carmen Sæculare* on such an occasion.

APOLLO BELVEDERE, a statue, perhaps the greatest existing work of ancient art, representing the god Apollo at the moment of his victory over the Python. It was found in 1503 among the ruins of ancient Antium (now Porto d'Anzo), and derives its name from its position in the Belvedere of the Vatican, where it was placed by Pope Julius II., who had purchased it before his accession to the papal throne. It was removed by the French in 1797, but replaced after 1815. The statue is of heroic size, and shows the very perfection of manly beauty. The god stands with the left arm extended, still holding the bow, while his right hand, which has just left the string, is near his hip. This right hand and part of the right arm, as well as the left hand, were wanting in the statue when found, and were restored by Angelo da Montorsoli, a pupil of Michel Angelo. The figure is nude; only a short cloak hangs over the left shoulder. The breast is full and dilated; the muscles are conspicuous, though not exaggerated; the body seems a little thin about the hips, but is poised with such singular grace as to impart to the whole a beauty hardly possessed by any other statue. The sculptor is unknown; many attribute the statue to Agasias the Ephesian, others to Praxiteles or Calamis; but its origin and date must remain a matter of conjecture.

APOLLODORUS OF CHARYSTES, a comic poet of the new Attic comedy, flourished about the middle of the 3d century B. C. Terence took from him the plots of several of his plays.

APOLLONIA, a city of ancient Illyria or New Epirus, near the mouth of the river Aous (now the Voytza in Albania). It was founded by colonists from Corinth and Coreyra. The place, having suffered much from the attacks of the Illyrians, sought the protection of the Romans, and remained faithful to them during the Macedonian war. A few huts, a monastery, and a church, together with the remains of two temples, are the vestiges of the city.

APOLLONIUS PERGÆUS, an ancient geometer of Alexandria, born at Perga in Pamphylia, flourished about 230 B. C. His work upon the conic sections gained for him from his contemporaries the title of the Geometer. Only four books of this work have come down to us in the original language. Three more are preserved in Arabic, and the 8th is lost.

APOLLONIUS RHODIUS, the author of the *Argonautics*, an epic poem on the voyage of the *Argo*, flourished at the close of the 3d century B. C. He spent much of his youth in Alexandria, of which he is supposed to have been a native, and there composed his poem, which is still extant. He read it publicly, but the Alexandrians treated it with contempt; and this so angered him that he left the city and went to Rhodes, where he long resided, taking his surname from the town. The Rhodians received his work with the greatest favor. Later in life he returned to Alexandria, and, by reading the revised poem in full, so changed the opinion of it held by the Alexandrians that they covered him with honors. He was made librarian of the museum, an office which he is supposed to have held till his death. He was buried in the same tomb with Callimachus, with whom in his youth he had had a violent quarrel regarding the merits of his poem. His epic, in four books (*Argonautica*), gives a simple, beautiful, and vigorous sketch of the *Argo's* expedition. Apollonius also wrote epigrams (of which one on Callimachus is still extant), and several works which are lost.

APOLLONIUS TYANEUS, a Pythagorean philosopher, born at Tyana, Cappadocia, about 4 B. C. He travelled for many years through Asia Minor and the East, disputing everywhere concerning the mysteries of nature and religion. From Babylon he journeyed to India, where he disputed with the Brahmans on the comparative merits of the Alexandrine and oriental philosophers. He laid claim to supernatural power, and is said to have received from priests and people divine honors. At Athens he was denied admission to the Eleusinian mysteries, because he was regarded as a magician. It was only by force that he obtained an entrance into the cave of Trophonius, where he is said to have found the theological books of Pythagoras. At Rome he was arrested and brought to trial as a practiser of the black art, but acquitted. After visiting Spain, Africa, and Greece a second time, he bent his course to Alexandria. Vespasian was then in Egypt preparing to strike a blow for the imperial purple, and hearing of Apollonius's arrival, he determined to turn to account the influence which the philosopher possessed with the people as a prophet and thaumaturgist. Accordingly, when Vespasian, on his entrance into the city, was met by the magistrates and philosophers, he inquired with affected anxiety whether the Tyanean was present. Being answered in the negative, he at once proceeded to the place where he was, and

entreated Apollonius to make him emperor. The Pythagorean rejoined that he had already done it in praying to the gods for a just and venerable sovereign. At a council of philosophers presently held in Alexandria to consider the claims of Vespasian, Apollonius warmly advocated the cause of his new patron. Having, after the death of Titus (81), been accused of attempting to excite the Greek cities of Asia against the tyrant Domitian, he voluntarily surrendered himself, and was cast into prison at Rome loaded with chains. His biographer, Philostratus, says that he freed himself from captivity by the exercise of his supernatural powers. Apollonius himself, at a subsequent period, publicly stated in Greece that he owed his liberty to the clemency of the emperor. Several cities contended for the honor of having been the last residence of Apollonius, but it seems most probable that his old age was spent at Ephesus. Tyana, the place of his birth, was raised to the rank of a sacred city, and invested with peculiar privileges, and here during the supremacy of paganism a temple existed in which the Pythagorean was worshipped. He used no animal food, wore no woollen garment, suffered his hair to grow, and abjured the society of women. As a philosopher he labored to reconcile the oriental and Greek systems with the symbolism of his master. As a religious reformer he sought to restore the rites of paganism to their pristine purity. He held that all sensible objects were material and corruptible; that all sacrifice was impure in the sight of the gods; and that even prayer itself became polluted when it passed the lips of the supplicant. Except some letters and a reply against a complaint of the philosopher Euphrates, all his works have perished.

APOLLOS, an Alexandrian Jew, converted to Christianity about A. D. 54. He began (Acts xviii. 24) to preach at Ephesus, "knowing only the baptism of John," and was afterward instructed by Aquila and Priscilla, and sent into Achaia. At Corinth he was very popular, dividing fame with Paul and Peter, as it appears from that apostle's reference in 1 Cor. i. 12: "Every one of you saith, I am of Paul, and I of Apollos, and I of Cephas."

APOLLYON (Gr. Ἀπολλύων, the destroyer), used in Rev. ix. 11 as a translation of the Hebrew *abaddon*. In the Old Testament *abaddon* signifies the subterranean region, or place of the dead, equivalent to the Greek *Hades*. The rabbins, however, divide this region into two portions, the upper being the grave, the lower *abaddon*, founding this distinction especially upon Ps. lxxxviii. 11, "Shall thy loving kindness be declared in the grave, or thy faithfulness in destruction [*abaddon*]?" In Revelation Apollyon is personified as the angel who has dominion over the bottomless pit, the chief of the destroying agents, represented under the figure of locusts, who emerge from the abyss at the sounding of the fifth trumpet. Some apocalyptic expositors have held that

the locusts represent the Saracens, and that Apollyon means especially Mohammed; but it is more likely that the figure is a general representation of the convulsions attending the breaking down of paganism and the establishment of Christianity. In the "Pilgrim's Progress" Apollyon is the name of the evil spirit encountered by Christian in the valley of the shadow of death; hence the word has come to be almost a synonyme for the chief of the fallen angels.

APOPLEXY. See BRAIN, DISEASES OF THE.

APOSTLES (Gr. ἀπόστολοι, the sent, messengers), a title bestowed in the New Testament upon all who were commissioned to preach the gospel of Christ, but especially upon the twelve whom Jesus chose from the whole number of his disciples to be his heralds among Jews and Gentiles. Their names were—Simon Peter, Andrew, James (son of Zebedee), John, Philip, Bartholomew, Thomas, Matthew (Levi), James (son of Alphaeus), Lebbeus (Thaddeus), Simon, and Judas Iscariot. They were mostly Galileans and laboring people, all being fishermen but Matthew, who was a tax-gatherer. Some of them were connections of the family of Jesus or companions of his youth, and they had been disciples of John the Baptist before Christ's appearance. They accompanied Christ on his journeys, witnessed his works, heard his public teaching and discussions, and the more intimate of them (Peter, James, and John) were often admitted to the privacy of his meditations. During his lifetime the apostles undertook one missionary expedition at their Master's bidding; but after the resurrection the eleven remained in Jerusalem, not openly distinguished from other Jews. The place of Judas was filled by Matthias. It was not until the day of Pentecost that their work commenced in earnest with the public announcement of Christ as the Messiah. The persecution to which Stephen fell a victim scattered the believers (some think only those of Greek extraction); but the apostles still continued in the city or in Judea, Peter alone venturing reluctantly to make a short journey as far as Casarea, where he baptized some un-circumcised people.—The work assigned by Christ of preaching the gospel to "all the world," left unattempted by the original apostles, who wished to confine its blessings to the circumcised Jews, was first fully undertaken by Paul, a man who had never seen Jesus on earth, had received no commission from him like the rest, had sought from Peter and his companions no authoritative exposition of the Master's truth, and was at first an object of suspicion. All that we know from historical records respecting the apostles is gathered from the letters of Paul and the book of Acts, though legends about all of them were early current, recounting their voyages, sufferings, and martyrdoms. An interesting account of the apostles' labors is found in Neander's "Planting and Training of the Christian Church."

Schwegler's *Nachapostolisches Zeitalter* should also be consulted.

APOSTLES' CREED, the oldest, most comprehensive, and most universally accepted creed of Christendom, interesting from its antiquity, and still more from its general adoption by the Greek, Roman, and Protestant churches. It reads as follows: "I believe in God the Father Almighty (Maker of heaven and earth); and in Jesus Christ his only Son our Lord; who was conceived by the Holy Ghost, born of the Virgin Mary; suffered under Pontius Pilate, was crucified, (dead,) and buried; (he descended into hell.) the third day he rose from the dead; he ascended into heaven, and sitteth on the right hand of (God) the Father (Almighty); from thence he shall come to judge the quick and the dead. I believe in the Holy Ghost; the holy (catholic) church, (the communion of saints;) the forgiveness of sins; the resurrection of the body; (and the life everlasting.) Amen." The passages enclosed in parentheses are additions to the original form, which was complete by the middle of the 2d century. The nucleus of the creed is supposed to have been the formula of baptism, "in the name of the Father, and of the Son, and of the Holy Ghost," to which the other articles were appended, the whole forming a brief summary of historical statements from the New Testament in regard to the Father, Son, and Spirit. The creed is rather an epitome of recorded facts than a system of speculative opinions, and was never designed nor used to express the philosophical thoughts of the church. The impression that this venerable symbol was regarded as a secret formula, part of the *disciplina arcani*, is erroneous. The tradition that it was made by the apostles themselves, who at a meeting in Jerusalem contributed each an article toward an authentic, compendious, and unchangeable rule of faith, rests upon no historical evidence.

APOSTOLICI. I. A sect of the 2d century, mentioned by St. Augustine, concerning which very little is known. They considered marriage and individual possession of property mortal sins. II. A sect of the 12th century, mostly from the lower classes of society, who would not take an oath, nor shave, nor cut their hair, nor marry. Although their lives were blameless, many of them were executed at Cologne. III. A sect founded about 1260 by Gerard de Segarelli of Parma, a young man who had been rejected from the Franciscan order. They believed that the kingdom of heaven was soon to come, and went barefoot through Italy, Switzerland, and France, preaching, begging, and singing. They rejected marriage, but lived in intimacy with females whom they called spiritual sisters, and who accompanied them on their journeys. Segarelli was burned as a heretic in 1300. The sect continued to live a while longer under Doleino, a Milanese, but soon became reduced to banditti, and in 1307 the movement ceased.

APOTHECARY (Lat. *apothecarius*, from Gr. *ἀποθήκη*, a shop or store), one who prepares and dispenses medicines. Apothecaries formerly sold herbs and drugs and spices, and by long practice in the art of preparing tinctures, sirups, powders, extracts, pills, and medicated waters, they became a special corporation, distinct from grocers and in some places from druggists, and were organized into a privileged body in the civilized parts of Europe, during the middle ages. In England the corporation still exists, in virtue of a royal charter, and with power to confer licenses on its members, who are invested with the right to administer medicine, as well as to prepare it and sell it in shops. A large proportion of the medical practitioners in England are only apothecaries; but the corporation enlarges its curriculum of studies and examinations as occasion may require. The royal college of surgeons in London also has a charter, and a right to give diplomas, which are honorary, and confer no legal right to practise medicine and to sue for payment. Most young apothecaries, however, now obtain them before they venture to practise as surgeons. In France the old corporation of apothecary druggists has been dissolved, and a new chartered corporation of *pharmaciens* has been substituted in its place. These keep shops, prepare medicines, and make up prescriptions, but have no legal right to practise as physicians. In the United States there is neither law nor custom to prevent an apothecary from practising as a physician. It is only lately that any legal restrictions have been placed upon the dispensing of the most powerful drugs by any boy whom the proprietor of an apothecary's shop might choose to employ.—In apothecaries' weight, used in dispensing medicines, the pound (lb) is divided into 12 ounces ($\frac{1}{2}$), the ounce into 8 drams ($\frac{1}{3}$), the dram into 3 scruples ($\frac{1}{4}$), and the scruple into 20 grains (grs.). In the wholesale drug trade avoirdupois weight is used.

APPALACHEE BAY, a large open bay on the S. W. coast of Florida in the gulf of Mexico, having a breadth of about 45 m., and an extent inland of 18 m. There is a wide passage from the bay, 10 feet deep, leading to the town of St. Mark's, which furnishes excellent anchorage ground.

APPALACHEES, an Indian tribe of Florida, living on a bay which still bears their name. They were of the same family as the Choctaws, and were very numerous. They were at first not friendly to the Spaniards, and made war on them at intervals down to 1638. A Spanish post was established there, and missionaries soon won them over, care being taken to instruct the chiefs, many of whom learned to read and write. The oppression of the Spanish commanders led to a revolt about 1687; and the Spaniards after reducing them compelled many to work on the fortifications. Their appeal to the king in 1688, signed by the chiefs, is still extant. While this discontent prevailed, the English and their Indian allies

invaded the country of the Appalachees, destroying many towns and killing or carrying off great numbers of the people. In 1704 St. Mark's was taken and the missionaries were put to death. The tribe was now reduced from 7,000 to about 400. On the settlement of Louisiana a portion removed to St. Louis in the vicinity of Mobile, while the Spaniards gathered the remainder at Soledad. After 1722 they disappear as a tribe, being probably absorbed in the Choctaw nation.

APPALACHIAN MOUNTAINS, the great range of mountains, called also the Alleghanies, which extends from that part of Canada lying between the New England states and the St. Lawrence river, through the whole length of Vermont, across the western part of Massachusetts and the middle Atlantic states, to the northern part of Alabama. The name Appalachian was given to the mountains by the Spaniards under De Soto, who derived it from the neighboring Indians. The name Alleghany, given by the English settlers of the north, was received from the Indians, and supposed to mean endless. The White mountains of New Hampshire and the Adirondack mountains of New York are really outliers of this range, though separated from it by wide tracts of low elevation. In their Alpine forms and more metamorphic structure, they present also features somewhat different from those which are especially peculiar to the Appalachian range. The Catskills form a link of the main range. These groups will all be found described under their own names. Not including the lateral ranges, the greatest width of the Appalachian chain is about 100 m. This is in Pennsylvania and Maryland, about midway of its course. Its extreme length is about 1,300 m. At either end its termination is not well defined, the mountains sinking away and being lost in the hilly country that succeeds to them, and at the south its gneissoid and other ancient rocks gradually disappearing beneath the cretaceous formations of this region. In all their extent the Appalachian mountains are remarkable, not for their great elevation, nor for their striking peaks, nor for any feature that distinguishes one portion of them from the rest, but for a singular uniformity of outline, particularly of that which defines the summit of the ridges, as well as that which marks their direction. While varying little in height, the ridges pursue a remarkably straight course, sometimes hardly diverging from a straight line for a distance of 50 or 60 m., and one ridge succeeding beyond another, all continuing the same general course in parallel lines, like successive waves of the sea. As one curves round into a new direction, all curve with it. Thus the valleys between the ridges preserve a uniform width, and are as remarkable for their parallelism as are the hills which bound them. An able paper upon "The Physical Structure of the Appalachian Chain" was read before the American association of geologists

and naturalists in 1842, by the Profs. Rogers, who were at the head of the geological surveys of Pennsylvania and Virginia, and who had extended their observations into the continuations of the chain N. and S. from these states. This paper is still the most complete treatise upon this subject. Prof. Guyot has also given much attention to the physical structure of these mountains, and made careful barometrical measurements of several of their highest summits, both near their northern and southern extremities.—The general course of the Alleghanies is that of the coast line opposite to them. The sea makes its nearest approach to them at the mouth of the Hudson river, which is only 50 m. from the passage of this river through the Highlands. Thence as far S. as Cape Hatteras, the width of the Atlantic slope gradually increases, till the space between the coast and the Blue Ridge is about 200 m.; and so it continues to the southern extremity of the mountains. This space is a hilly district, gradually becoming of higher elevation as it extends back from the coast. In New England its average height at the base of the mountains is about 500 ft. above the sea; in Pennsylvania, 300; in Virginia, 500; and further S. 1,200. From the mountains to the lowest falls of the streams over the edge of the granitic platform, this is for the most part a region of the lowest stratified, metamorphic, and granitic rocks. These lowest falls mark the head of navigation of the streams, and the descent to the lower and more level platform of the upper secondary and tertiary formations, which in the southern states stretch along the coast in a belt sometimes reaching 100 m. in width. The eastern ridges of the chain, rising from their elevated base, do not present the appearance of the height above the sea which they actually reach; and on their western slope, which stretches far away toward the Mississippi, their height is still more completely lost in the elevated and wide-spread plateau. Between Lake Champlain and Lake Ontario, this western table land is 1,500 ft. above the sea, and from it as a base rise the high summits of the Adirondaek mountains. In Virginia and Tennessee, as observed by Prof. Guyot, the bottom of the valley W. of the Alleghanies is from 1,000 to 2,000 ft. above the sea, and beyond it for 100 m. W. extends a plateau of 1,500 to 2,000 ft. elevation, traversed by longitudinal ridges. All the cross sections from the eastern edge of the granite present first the slightly undulating profile of the Atlantic slope, which is succeeded by the sudden rise to the highest elevation, and this by the wave-like descent and ascent across the valleys and the ridges, and finally terminate in the gradual descent on the western table land. As first pointed out by Prof. Rogers, the same law is found to obtain in this chain and in the Jura mountains, of steepest general slopes toward the east; but of individual ridges the gentler slopes are toward the east, and the steepest inclina-

tions toward the west. In the mid-region of the chain—in New Jersey, Pennsylvania, and Maryland—where the breadth is greatest, the height appears to be correspondingly diminished. The summits, valleys, and table land all reach here their least elevation. The highest summits are but little over 2,000 ft. above the sea. Still the barrier between the eastern and western waters is complete; and no clean cut through the range is anywhere found, excepting that of the Mohawk river in New York, the highest elevation of which is only 400 ft. above the sea. Toward the north and the south from this central portion, the plateau becomes more elevated, as well as the summits that rise up from it. In North Carolina, near the borders of Tennessee, and in the northern part of Buncombe county, the base of the Black mountains, which have been an especial subject of examination by Prof. Guyot, is found to extend from 100 to 150 m. in length, with an elevation of 2,000 ft. Above this many summits are found reaching more than 4,500 ft. higher, as the Black Dome, the height of which above the sea is 6,760 ft.; the Balsam Cone, 6,668; the Black Brother, 6,671; Cat-tail peak, 6,595; Hairy Bear, 6,597, &c. The great elevation of this group makes it the culminating point of the system. Mt. Washington in New Hampshire, though found by the measurement of Prof. Guyot to be but 6,288 ft. above the sea, which measurement differs only three feet from that made by the officers of the coast survey, appears much more elevated than the summits of the Black mountains, from its rising from a plateau of not half the height of the base of this group.—In the southern part of Pennsylvania other parallel ridges succeed to the Alleghany mountains; Negro mountain, Laurel hill, and Chestnut ridge, each a repetition of the other, at distances about 10 m. apart, and each occupying nearly as great a breadth as the valleys which separate them. The capping of their summits is the conglomerate rocks, which underlie the coal measures. These strata arch over the crests of the ridges, projecting in bold cliffs, and on each slope dipping beneath the coal measures, which in the valley hills attain their greatest thickness. Thus the same strata appear upon the summits, and in undulating lines pass beneath the valleys to reappear upon the crest of the next ridge, and so on till, dipping down the western slope of Chestnut ridge, the coal measures spread in nearly horizontal strata over the western portion of Pennsylvania, Maryland, and Virginia. Their lowermost layers reappear as they rise to the surface upon the other margin of the great coal basin, as far into Ohio as Zanesville, and thence along a line extending to the mouth of the Scioto. In the gentleness of the dips of the strata, this western slope presents a striking contrast to the highly disturbed stratification of the Atlantic slope. There the rock formations, nearer the disturbing causes which have elevated the

mountains and metamorphosed the rocks of the most eastern ridges, are thrown into confused and intricate positions, and pressed into folds and wrinkles, the prevailing inclination of which is toward the southeast—as horizontal layers of heavy cloth, pressed laterally by irresistible force from one end of the pile, would be lifted into folds, whose general inclination, by the falling back of the arches, would be toward the direction where the force is applied. The direction of the line of force is that of the ridges themselves, or rather of the anticlinal and synclinal axes, the one being the crest of wave-like form into which the strata are thrown, and the other the trough. This, too, is the line of the great fissures, which, now filled with metallic ores, constitute the mineral veins of the chain. It is the line of the rents caused by the earthquakes of the present period; and it is regarded by the Profs. Rogers as the line along which the elevating force that lifted the mountains extended, moving onward at right angles to this line, with a wave-like motion, till the result was attained of placing the ridges in their present positions. Toward the southeast, whence the movement proceeded, the axes are crowded near together. Toward the northwest they are repeated at distances gradually increasing, till the undulations at last flatten out and die away in the horizontally stratified regions of the west. The straightness or regular curvature of these axes, and their parallelism in distinct groups, continued for distances sometimes amounting to over 100 m., without change in the stratification or topography, cannot fail to excite the astonishment of the geological observer. Among these axes are particularly noticed by the Profs. Rogers the straight axis of Montour's ridge in the Susquehanna region, which extends about 80 m.; the beautifully inflected axis of Jack's mountain, in the Potomac region, 90 m. long; and that of the Knobly mountain, nearly a continuation of the last named, itself 100 m. long. In S. W. Virginia, the straight axis of Clinch mountain is traced for more than 120 m.—The strata of the Appalachian system are all of marine or terrestrial origin. The fossils they contain are all of families belonging to the salt water, or plants of terrestrial growth. The latest or uppermost groups are those of the coal formation. Throughout the whole chain none of the stratified rocks belong to a later epoch. Their elevation, then, must have taken place previously to those periods, when the upper secondary rocks, that lap upon the extreme eastern border of the Appalachian formations, were deposited, and previously to those still later periods when the great deposits of tertiary marls, sandstones, and clays were produced, which cover the S. E. part of our country. These mountains are then of much older date than the Alps or the Andes, upon the high summits of both of which rest the rocks of these later formations, containing

their characteristic marine fossils. Raised probably by many successive impulses exerted on the same lines (it may be after long intervals of rest), the rush of the retreating waters appears to have opened those gaps through the ridges, which constitute a peculiar and most interesting feature in the topography and scenery of these mountains, and which could not have been produced by the action of any existing streams. The same rush of waters, acting upon piles of strata of various degrees of hardness, and consequent capacities of resistance, impressed upon these the forms appropriate to these properties. This is seen in the sharp outline of single beds of sandstone, which project from the sides of the hill, around which they outcrop; and in the receding of the profile of the mountain against the beds of softer shales and slates. It is seen on a grander scale in the peculiar forms which each of the rock formations gives to the hills or mountains it composes, and which enables one to recognize it wherever met with by a glance at the topography.—The regular arrangement of the rock formations throughout all their foldings and undulations is rarely disturbed by any of those sudden breaks which are common in other countries, and which bring into contact, by the displacement of portions of the series, strata usually far separated from each other. These "faults," however, are met with in several of the states, but particularly in S. W. Virginia, where they extend for about 100 m. in length, their course being the same as that of the anticlinal axes out of which they grow. They appear to have resulted from the lateral thrust toward the northwest of the folded piles of strata. They are observed, always beginning on the N. W. side of the anticlinal axes, in tracing these along their course, the strata on this side becoming steeper and steeper, till at last they are inverted, and dip toward the southeast. At this point the strata appear to have burst asunder along the line of greatest curvature, and the S. E. portion to have been lifted up, bringing its lower strata against the higher members on the other side of the line of fracture. The depth of this dislocation, or the extent of the displacement, increases toward the centre of the line of fault; and where the length of this line, as in the district under consideration, stretches along for 100 m. or more, it cannot appear disproportional that the vertical displacement should in its central portions amount to $\frac{1}{20}$ of this distance; and that the lower groups of the Appalachian system, usually separated by intervening strata of four or five miles in thickness, should be brought in contact, so that the edges of one series abut against the edges of the other. Thus the lower limestones of the great valley of Virginia are seen in Montgomery county, and thence westward along the line of the Virginia and Tennessee railroad, in vertical position, with the strata of the far more elevated series containing coal

beds dipping toward them, as if the more recent formations passed beneath these ancient groups. The thermal springs, which are of frequent occurrence along the Appalachian chain, and particularly so in Virginia, flow out almost universally on the lines of anticlinal axes, or of the faults. Their elevated temperature indicates the great depths from which they rise, and consequently that to which the folds and fractures of the stratification reach.—The geological formations of the Appalachian belt, comprising all the groups from the granite to the coal, are abundantly productive in the most important ores and minerals, which especially belong to these different formations. In the ancient granitic rocks which skirt the edge of the lower stratified formations, and sometimes spread out over broad areas, as in the mountainous region W. of Lake Champlain, in the highlands of New York and New Jersey, are found inexhaustible repositories of magnetic iron ores, which already are worked to great extent in connection with the valuable beds of hematite ores that are found conveniently near them, ranging from Canada to Alabama along the line of the great Appalachian valley. These beds occur in great depressions in the lower limestones and metamorphic slates of this range, and sometimes in veins in the same rocks, and are worked in every one of the states through which this passes, everywhere presenting the same peculiar features. They are frequently of extraordinary extent, and though worked in several instances for more than 100 years, the actual depth to which they reach, and their real nature, have never been fully explored. Together with the magnetic ores, they furnish the supplies for a very large proportion of all the iron manufactured in the United States; and the numerous bodies of them still untouched are a provision for still larger demands for generations to come. The value of these repositories can hardly be overestimated, particularly when considered in connection with the long extent of their range, not far back from the coast, and the enormous supplies of mineral coal that can be conveniently brought to effect their reduction. Far more valuable are they than the gold found in the granitic and metamorphic rocks of the eastern ranges, though this, judging from the production of certain localities in the southern states, would, if exposed by the great irregularities of the surface, like those of California, be found as rich and abundant as there. It is worked in alluvial deposits enriched from the auriferous veins; and these also contain ores of copper and lead, and occasionally of silver. These deposits and veins are met with in the valley of the Chaudière below Quebec, and are again seen in a few localities in Vermont; but their great development is on the eastern borders of the Appalachians S. of the Potomac. The copper ores met with in the rocks of the Appalachian system have never proved of great importance. They are found along the range

of the talcose and micaceous slates of the Blue Ridge, as well as associated with the gold further toward the southeast. In Virginia these slates produce some workable beds of lead ore, and display occasionally attractive appearances of copper. In New Jersey the same range produces the remarkable red oxides of zinc associated with Franklinite, which are worked together, the one to produce the white zinc paint, and the other a superior quality of iron for the manufacture of steel. Further S. along the same belt are found, in the Lehigh valley and in Lancaster county, Pa., the valuable silicates and carbonates of zinc, called calamine, which are worked for the same purpose as the red oxides of New Jersey. Veins of lead ore are found in several of the formations; and in Wythe county in S. W. Virginia a mine in the great limestone formation has been worked with some interruptions for more than 100 years. These lead veins, however, of the lower members of the Appalachian system, have for the most part proved of little importance; indeed, throughout the range of the mountains none of the formations above the metamorphic rocks are rich in any other metallic ores than the hematites which are occasionally met with, the red fossiliferous iron ores of Formation No. V. of the Pennsylvanian survey, called in New York the Clinton group, and the argillaceous ores of the coal measures. No rock formation is more useful to man for the variety and value of its productions than the true coal formation. It furnishes the great supplies of anthracite and bituminous coal, beds of fire clay, and west of the Alleghany ridge abundant beds of limestone. Salt water is obtained by boring artesian wells to lower members of the series, and the brine flows up or is pumped up into the valleys, to be evaporated by the combustion of the coal found in the neighboring hills. In many localities, where the salt-bearing rocks approach the surface, the brine is more readily obtained in large quantities, and the coal is transported for its evaporation. The formations that furnish the salt also contain great beds of gypsum. Onondaga county in New York is famous for these productions, and in Washington county in S. W. Virginia solid beds of salt are struck in the midst of the most extensive plaster deposits.—From one extremity of their range to the other, the Alleghanies have furnished large supplies of the valuable white pine; and many of the less accessible districts of the belt still abound with it. Far toward the north, upon the better soils of the mountains, the hard-wood forests prevail—the fine sugar maple, of the curly and bird's-eye varieties, and the white birch. The ash and the beech also attain their highest state of perfection in the most fertile soil of these northern mountains. Upon the poorer lands, and along the ravines of the mountains, the "black growth" flourishes—the evergreens, as the different species of the pine family, the spruce, the hemlock, cedar, and

balsam fir; and in the swamps, the hackmatack or larch. The varieties of the oak appear further S. upon the range, these and the chestnut taking the place of the maple, birch, and beech, and, to some extent, of the evergreens also. The large cherry tree, so valuable for its timber, is met with in Pennsylvania, scattered upon the mountains; in W. and S. W. Virginia it forms forests of itself. The white oak, the white poplar, the white and yellow pines, and the chestnut are the valuable forest trees of the mountains of Virginia. In some localities still further south, the dark growth of the conifera covers the summits, as found, for instance, by Prof. Guyot in the group in North Carolina named the Black mountains from the dark foliage of its balsam firs, spruce, and hemlock. Among the flowering shrubs, none are more beautiful than the varieties of *kalnia*, *azalea*, and *rhododendron*, which are found in the greatest profusion upon the slopes of the Alleghanies and along their watercourses, giving to the rough places of the mountains the rich colors of cultivated gardens.

APPALACHICOLA. I. A river of W. Florida, formed by the union of the Chatahoochee and Flint rivers at the S. W. angle of Georgia, flows S. about 75 m. into St. George's sound, through an estuary called Appalachiecola bay. It is navigable for steamboats through its whole course, and with its branches is supposed to drain not far from 20,000 sq. m. The tide runs up 60 m. II. A town and port of entry, capital of Franklin county, Fla., situated on a bluff at the mouth of the preceding river, 65 m. S. W. of Tallahassee; pop. in 1870, 1,129; in 1860, 1,904. Large quantities of cotton are shipped here by steamboats. In 1870 the number of vessels registered, enrolled, and licensed was 21, with an aggregate tonnage of 2,033 tons; of these 7 were steamers with a tonnage of 1,587 tons.

APPANOOSE, a S. county of Iowa, adjoining Missouri; area, 510 sq. m.; pop. in 1870, 16,456. The North Missouri railroad traverses it. The river Chariton, which flows through it, and numerous smaller streams, furnish ample water power, while the rolling prairies which cover a large part of the surface are fertile, and the watercourses are bordered by tracts of timber. Large beds of coal have been found at several points. In 1870 the county produced 134,411 bushels of wheat, 986,280 of corn, 322,256 of oats, 59,079 of potatoes, 83,784 lbs. of wool, 484,147 of butter, 22,659 tons of hay, and 37,150 gallons of sorghum molasses. Capital, Centerville.

APPARATUS, in physiology, a group or collection of different organs, which are associated in the performance of some function in which each one bears a particular part. Thus, the heart, arteries, veins, and capillaries together constitute the circulatory apparatus. The bones, ligaments, tendons, and muscles of the limbs form the apparatus of locomotion. The mouth, teeth, tongue, stomach, and intestine, with the accessory glandular organs, are the

digestive apparatus. An apparatus may include not only different organs, but also entire systems. Thus the circulatory apparatus comprises not only the heart, which is an organ by itself, but also the arterial system, the venous system, and the capillary system. All of these, however, are essential to the circulation of the blood, and each performs its own special part in the function.

APPARITION, a spectral illusion, by which imaginary objects are presented to the senses with such vividness that they are believed to be real. This form of illusion, the result of some abnormal state of the brain, concerning which medical science has given thus far only incomplete information, has been the cause of much superstition. The apparitions seen in actual delirium, or by those obviously insane, do not of course fall within the scope of this article; and the well authenticated instances in which apparitions have been seen by men of ordinarily clear intellect, and apparently in their customary good health, are so mingled with impostures and exaggerations that it is difficult to make them the ground of scientific investigation. But there are some cases where men of the highest intellectual power have had this cerebral affection, yet have retained enough acuteness of observation to investigate their own disease, and describe the apparitions coolly and accurately, though knowing them to be illusory. The most noteworthy of these cases is that of Nicolai, an eminent publisher in Berlin, who in 1791 was for some months constantly subject to spectral illusions, which presented to him the figures of friends, unknown persons, and singular animals, which accompanied him everywhere, went through all the movements belonging to their real prototypes, and even spoke to him. Conscious of their character, he observed them so accurately as to be able to write a scientific paper upon them for the philosophical society of Berlin. He was ultimately cured by blood-letting. Many similar instances are recorded in the volumes referred to at the close of this article.—Some well authenticated accounts of apparitions appearing to persons a short time before death do not in the present state of medical inquiry admit of so satisfactory an explanation. That both the apparitions actually seen and those in which the superstitious believe should most frequently represent the forms of dead friends, is conceded to be natural; for the brains of those who see or fancy they see them are generally excited by grief or filled with morbid fears of death. Yet these causes, and the natural tendencies of superstitious minds and low states of knowledge, gave rise to the popular belief in ghosts.—See Dr. John Ferriar's "Essay toward a Theory of Apparitions" (London, 1813); Dr. Samuel Hibbert's "Sketches of the Philosophy of Apparitions" (Edinburgh, 1824); Sir Walter Scott's "Letters on Demonology and Witchcraft" (Edinburgh, 1830); Mrs. Crowe's "Night Side of Nature" (London,

1848); Jung Stilling's *Geisterkunde*, translated into English under the title "Pneumatology" (New York, 1851); Dr. Brierre de Boismont's "Hallucinations, or the Rational Theory of Apparitions," &c. (English translation, Philadelphia, 1853); Robert Dale Owen's "Footfalls on the Boundary of Another World" (Philadelphia, 1860), and his "Debatable Land" (New York, 1872). See also, in this work, DEMONOLOGY, SPIRITUALISM, and WITCHCRAFT.

APPEAL, in law, the proceeding by which a decision of a court or judge is taken to a superior tribunal for review. Though appeal is commonly used in the law to describe all revisory proceedings, yet the word strictly belongs to that remedy of the civil law which takes up the whole cause to the higher court and subjects facts as well as law to review. At common law an appellate court takes cognizance characteristically only of matters of law. Matters of fact in that system can be revised only upon a new trial. For example, if a party in a suit conceives that a verdict against him is not sustained by the evidence, he applies to the court where the case was tried for a new trial. Upon an appeal from the decision on that motion, the appellate court may or may not sustain it; but if it does not, it will not itself pronounce a verdict on the facts, but remits the cause to the lower court, to be tried there again by a jury.—The review upon points of law is had at common law upon a writ of error, while the appeal is used in courts which follow the practice of the civil law. The distinction between the two modes of review is now abolished in many of our states, but it still remains in the procedure of our federal courts. In admiralty and equity causes in those courts, matters of fact as well as of law are ordinarily tried in the first instance by a judge without a jury; and appeals from sentences or decrees in such causes carry up the whole case, and the appellate court passes upon the questions of fact and of law alike. But common law causes—the ordinary issues, for example, which are tried with a jury—go up to the appellate court upon a writ of error, and are revised there only in matters of law.—The proceedings upon appeal are in all our states regulated by statutes. Indeed, without some such authority the right of appeal does not exist at all. The subject of appeal is ordinarily the final judgment or action of the inferior court, and it must be the final decision upon the substantial matter and merits of the cause. Orders of the court upon mere points of practice in the progress of the action, which do not involve its merits, or which rest in the pure discretion of the court below, are not subjects of review. But a plain abuse of judicial discretion, or a clear mistake in exercising it, may give good grounds for appeal; and so may the refusal of the court below to exercise a discretionary power on the mistaken ground that it did not possess it. A party cannot appeal from a judgment entered against him on his default or con-

sent, nor from his own judgment of nonsuit, nor where he has agreed that the judgment of the lower court shall be final. The right of appeal may also be lost by taking proceedings on the footing of the decision, and especially by accepting any benefit under it. Properly, only a party to the record may appeal, and he only when he is aggrieved or injured by the decision; but he may be injured by a judgment, even in his favor, which is less favorable to him than he is entitled to, and in such a case he may appeal. A party to the record loses his right of appeal when he ceases to have any interest in the subject of the suit. If a party to the record dies, the right of appeal does not exist in his legal representative until he is substituted as a party in the action.—When the matter comes before the appellate court, the presumption is in favor of the judgment below, and the question is whether for any cause the judgment shall be reversed. Unless there is a majority or other controlling vote for reversal, the judgment stands affirmed of course. As the appellate court is inclined to sustain the decision of the court below unless there is clear reason for reversing it, it will not look into any part of the judgment which is not appealed from, nor take notice of any defects or insufficiencies in the proceedings below, unless they were formally objected to there—unless, indeed, the insufficiencies not objected to could not have been cured by the opposite party below if the objection had been stated; and even a ruling to which the appellant did object, but which has done him no substantial harm, will not be noticed. An erroneous charge of the judge below which is wholly extraneous and immaterial is no ground for reversal; nor will a verdict be set aside for misdirection of a judge, if the court can see from the whole evidence that the result would have been the same, if the objectionable instruction had not been given, or when the whole evidence justifies the verdict. If a judgment is right in point of law, it is no reason for reversing it that it cannot be sustained on the ground on which the court below proceeded.—When the appeal brings up questions as to the sufficiency of the evidence to support a verdict, an appellate court is disinclined to disturb the finding of the jury unless it is clearly and certainly against the weight of the evidence, the theory of our law being that the jury is the best tribunal for deciding all matters of fact. The same principle applies to findings by referees or by judges trying causes without juries; and in such cases, especially when the evidence was conflicting, the conclusions as to facts will not ordinarily be reversed.—In all our states the statutes will be found to contain provisions relating to the conditions of appeals, namely, in respect to the time within which they must be taken, the security which must be given, and the effect of the appeal in staying proceedings on the judgment appealed from. As to the time for taking the appeal, if it is prescribed

by statute, it cannot be extended by the court; and if an appeal is not taken within the limit, it is lost. Ordinarily, the appellant does not secure his right of appeal until he gives a bond or some such undertaking for costs; and he does not stay execution on the judgment against him unless he gives a like security for the payment of the amount of it in case it is affirmed.—With respect to criminal cases, the statutes of most of the states provide for reviews of verdicts upon writs of error at the instance of the convicted party. But there is ordinarily no appeal or remedy of that sort allowed to the people to reverse a judgment of acquittal. The constitution of the United States provides that no person shall be subject for the same offence to be twice put in jeopardy of life or limb, and no state can by any statutory provision take away from a criminal the benefit of this provision. Whenever statutes give any right to the state to have a review of a criminal trial, they must be construed with regard to the constitutional prohibition.—The supreme court of the United States exercises an appellate jurisdiction over the state courts, where the validity of a treaty or statute of, or authority exercised under, the United States is drawn in question, and the decision is against that validity; or where the validity of any state authority is drawn in question on the ground of its repugnancy to the constitution, treaties, or laws of the United States, and the decision is in favor of its validity; or where a question of construction upon the constitution, a treaty, or a statute of the United States arises, and the decision is against the claim under the authority of either. All civil causes, where the amount involved is sufficient, may be carried on appeal from the United States district court to the circuit court, and thence to the supreme court. The circuit courts exercise an appellate jurisdiction over all cases brought in the district courts, except where the matter in controversy is of a very small pecuniary value. Another mode of review in the supreme court is that upon a case certified from a circuit court. As this court may consist of two judges, they may, when they fail to agree, certify to the supreme court that they are divided in opinion, and in that event the case is entertained by the higher tribunal as upon an appeal. (See COURTS OF THE UNITED STATES.)—In New York the court of appeals is a court of appellate jurisdiction only. It has been lately reorganized under an amendment to the Constitution adopted in 1869. The amendment provides that the court shall consist of a chief justice and six associate judges, to be chosen by the electors of the state, and to hold office for 14 years. Five members of the court constitute a quorum, and the concurrence of four is essential to a decision. The present court has all the powers and jurisdiction which were possessed by the late court of appeals, which it displaced. It has exclusive jurisdiction to review upon appeal any actual determination made at a general term by the

supreme court, by the superior courts of New York and Buffalo, and by the court of common pleas of the city of New York in certain specified cases, among which the more important are the following: Upon appeal from a decision of any of these courts on final judgments in an action brought originally in it or removed into it from another court, it may reverse, affirm, or modify such judgment, or review any order in the case which involved the merits. The court also entertains appeals from orders affecting substantial rights when they in effect determine the action and prevent judgments from which appeals might be taken; or when such orders discontinue actions, or grant or refuse new trials, or strike out pleadings. But no appeal lies to the court of appeals from an order granting a new trial on a case or exceptions, unless the appellant with his notice of appeal gives also a consent that if the order appealed from be affirmed, absolute and final judgment may be forthwith entered against him. When the decision of any motion at a special term of the supreme court involves or is rested upon the constitutionality of any law of the state, an appeal may be taken first to the general term of that court, and thence to the court of appeals. No appeal to this court stays execution on a judgment unless it is accompanied with a bond securing payment of the judgment upon an affirmance or a dismissal of the appeal.—In England, the appellate jurisdiction of the court of chancery, where equity causes are heard originally by the master of the rolls or by the vice chancellors, is exercised by the lord chancellor alone, or sitting with one or both of the lords justices, or by these two alone. With respect to appeals in civil causes tried in either of the three superior courts (queen's bench, common pleas, and exchequer), the first appeal lies to the court of exchequer chamber, where the causes coming from either of the three are heard by the judges of the other two. In criminal cases appeals on questions of law arising in the courts of oyer and terminer or quarter sessions may go through the queen's bench to the exchequer chamber, but they are usually taken directly to the court for crown cases reserved. This latter court was created in 1848, and is composed of the judges of the three superior courts. It has final authority on questions raised by evidence, or in arrest of judgment; but on more important questions, like demurrers to indictments, the appellant may go through the queen's bench to the exchequer chamber, and thence to the house of lords. The house of lords is the supreme appellate judicature of the realm. By its ancient jurisdiction it reviews all errors brought up through the exchequer chamber from the common law courts of England and Ireland, and under more recent authority it entertains appeals from judgments of Scotch courts on questions of law. The house of lords also takes cognizance upon appeals on errors in crimi-

nal causes from all the inferior jurisdictions, except where the court for crown cases reserved has the final decision; and in chancery cases it hears appeals from all the English and Irish equity courts. By recent statutes appeals may also be taken to the house of lords from the probate courts of England and Ireland. There have been lately some emphatic complaints made about the weakness of the house of lords as an appellate court. Its decisions upon appeals are practically left entirely to the law lords, and it has not unfrequently happened that two or three of these have reversed judgments which had been sustained by a majority of the judges of the courts below. In one case of a recent date the prevailing judgment of the house of lords, given in fact by two persons only, coincided with the opinion of only four judges below, while the defeated party had had altogether seven judges in his favor. In another case the party who succeeded in the house of lords had had in the course of the suit through all the courts only four judges in all in his favor, while his opponent had had eight. Another supreme appellate tribunal is that of the queen in council. The judicial functions of the crown are however in fact delegated to the judicial committee of the privy council. This court revises judgments of the colonial courts throughout the empire, and sentences of the ecclesiastical and admiralty courts. The committee after consideration make their report to the crown, and its approval is signified by an order in council.—In France, incorrect decisions are also held in check by a system of appeals. The first regularly organized tribunals of appeal in France were about the reign of Louis IX. The French right of appeal, especially in criminal cases, seems to American or English observers to be often frivolously exercised. The French courts of appeal may discharge or amend the judgments of the courts below, and may reduce or increase punishments or the pecuniary awards of juries. The theory of the French appeal seems to be a submission of the facts as stated in the proceedings to the court of appeal, to whose judgment all deductions whatsoever are referred. Appeals from justices of the peace lie to the tribunals of first instance, composed of from three to twelve judges, divided into chambers of civil and criminal jurisdiction. The decisions of these tribunals and of the tribunals of commerce are reviewed in 27 higher courts, taking their names from the cities where they are established. Each of these courts is composed of at least 24 judges, and is usually divided into three chambers, one having cognizance of civil causes, one of criminal accusations, and one of police matters. In the civil chambers seven judges, and in the chamber of criminal accusations five judges must concur. On very important or difficult questions two of the chambers combine, and the decision must be concurred in by 14 judges. Appeals from these

courts go to the court of cassation. This court has 49 judges, and may on appeal annul the judgments of any of the inferior courts for any error of law apparent on the face of the proceedings. No new evidence is received in this court, while on appeals from the courts of first instance the proofs may be changed to any extent.—In Germany, the system of appeal was commenced in 1496, and is now greatly elaborated; the courts are of the first, second, and third instance. The appeals may be based either on matters of law or fact. Each kingdom has its own tribunals, and the smaller principalities are associated together in districts for the purposes of courts of appeal. The proceedings of the German courts, like those of the English court of chancery, are excessively prolix and tedious, and entirely in writing, the arguments only being oral, and their essence being contained in the pleadings, as deductions from the facts.—Besides the sense in which we in modern parlance use the word appeal, proceedings of historical interest known as appeals were formerly recognized in English law, wherein the term was used as derived from the French *appeler*, to summon or to challenge. An offender on his trial might by permission of the court confess the charge, and “appeal” another person as the instigator or accomplice of his crime, who thereupon might be put on his trial, or fight his accuser. If he was acquitted, or if he conquered, the accuser was hanged on his own confession; if convicted or vanquished, the accuser was pardoned, as for service done to the state. Sir Matthew Hale denounced this practice, and it fell into disuse, although by various statutes now repealed the indemnity, and even the reward of approvers, was long maintained. A party injured by a felony, his widow or heirs, might also appeal the offender for the price of blood, and subsequently for the purpose of punishment. This was distinct from a crown prosecution. The appellee, the person accused, could then demand his wager of battle, which the accuser, if a peer, a citizen of London, the widow, a priest, an infant, or person above 60, might decline. The appellant might also decline to fight if the evidence which he adduced raised a very violent presumption of the guilt of the appellee. The combat commenced by the appellee throwing down his glove, which was lifted by the appellant, whereupon each party affirmed categorically by an oath the truth of the accusation and denial, concluding, “and this I will prove against thee by my body.” Thereupon the parties must proceed to fight, with club and buckler, in the presence of the court, from sunrise to the appearance of the stars in the evening. If the appellant was vanquished, the appellee was acquitted, and had his action against the appellant, who was thereupon declared infamous; if the appellee was vanquished, he was hanged forthwith. The last occasion on which the appeal of felony and wager of battle were resorted to in England

was no longer ago than the year 1818, when the defendant was charged on such an appeal with the rape and murder of the appellant's sister. The appellee waged his battle, whereupon the appellant claimed that the evidence which he offered of the guilt of the accused was so conclusive as to exempt him, the appellant, from the necessity of fighting. But the judges decided that the evidence was insufficient to sustain the claim, though they offered to consider the point whether the wager of battle had not been waived by the form of the pleadings. But the appeal was withdrawn, and the accused was thereupon discharged. In the next year, 59 George III., the wager of battle was abolished by parliament. The case here referred to (*Ashford v. Thornton*) is reported at great length in *1 Barnewall and Alderson's Reports*, p. 405, where, in the elaborate arguments of counsel and in the opinions of the judges, will be found interesting matter upon this now obsolete topic of the law.

APPENZELL, a N. E. canton of Switzerland, entirely surrounded by the canton of St. Gall; area, 163 sq. m.; pop. in 1870, 60,639. The surface is irregular and hilly, but there are no considerable mountains, except the picturesque range of the Sentsis on the southern border. Offshoots of the Alps form parts of the eastern and western boundaries of the canton. The principal stream is the Sitter, a tributary of the Thur. Since 1597 the canton has been divided, by an agreement of the inhabitants, into two independent half-cantons, each containing a certain number of *Rhoden* (a Swiss word for communes or parishes). The northern and Protestant division, called *Outer Rhodes* (*Ausserrhoden*), contains about 100 sq. m. and 48,726 inhabitants, who carry on a considerable commerce, and manufacture cotton, linen, and silks, their silk-weaving and silk embroidery being among the most beautiful work of the kind in Europe. The southern and Roman Catholic division, called *Inner Rhodes* (*Innerrhoden*), contains about 52 sq. m. and 11,913 inhabitants, who devote themselves almost entirely to raising cattle, making butter and cheese, and other pastoral industries. *Outer Rhodes* sends two members to the federal council, and *Inner Rhodes* one. The capital of *Inner Rhodes* is *Appenzell*, a scattered village 6 m. S. by E. of *St. Gall*; of *Outer Rhodes*, *Trogen*. The inhabitants of both divisions are intelligent and quick of wit to a degree that has given them a celebrity throughout Switzerland; their habits are simple; they are fond of athletic exercises, and are excellent wrestlers and marksmen.—The canton belonged in the 8th century to the Helvetian dominions of the Frankish kings, and shared their fortunes, until in 1292 it was placed by *Adolphus of Nassau* under the control of the abbey of *St. Gall*, which had been founded in 720, and had always exercised great authority in its affairs. In consequence of the oppressions of the abbots, a rebellion broke out in 1401, and was renewed

at intervals for 50 years, finally resulting in the independence of the people. In 1452 the district joined seven other cantons for the sake of greater safety, and in 1513 it was received as a canton of the Swiss confederation. It derived its name from the monastery of *Abbatis Cella*, established by the monks of the abbey of *St. Gall*.

APPERLEY, *Charles James*, an English sporting writer, born in *Denbighshire* in 1777, died in *London*, May 19, 1843. After serving for a short time in a cavalry regiment, he began contributing under the name of "*Nimrod*" a series of articles to "*The Sporting Magazine*," which through his contributions soon doubled its circulation. The proprietor paid him a handsome annual salary and kept a stud of hunters for his use. His habits were expensive, however, and after the death of this liberal publisher, *Mr. Pittman*, the new owners of the magazine brought suit to recover moneys advanced; and to escape them "*Nimrod*" in 1830 established himself in a chateau near *Calais*. At the request of *Loekhart* he wrote for "*The Quarterly Review*" in 1827 some excellent papers, which were afterward collected under the title of "*The Chase, the Turf, and the Road*." Among his other works are: "*Hunting Reminiscences*," "*Life of a Sportsman*," "*Nimrod Abroad*," "*Remarks on the Choice of Horses*," and "*Treatise on the Horse and Hound*." His method of summering horses without throwing them out of condition is now generally adopted in *England* for hunters. It consists in feeding them on green food, in large loose boxes, on clay floors, their shoes being taken off, and their systems lowered by gentle alteratives, instead of the old method of turning them out to grass.

APPERT, *Benjamin Nicolas Marie*, a French philanthropist, born in *Paris* in 1797. At the age of 18 he formed the idea of establishing schools for mutual instruction in the department of *Le Nord*, and applied the principle in the following year to military organizations, with such success that *Marshal Gouvion St. Cyr*, minister of war, in 1818 appointed him professor of a normal school for officers and non-commissioned officers in *Paris*. Within three months 163 of these schools, with 20,000 pupils, were in full operation, and in the course of two years 100,000 soldiers had reaped the benefits of them. In 1822 he was imprisoned on a charge of favoring the escape of two political convicts. After his release he devoted several years to the improvement of the condition of prisons, and published a monthly *Journal des prisons* (1825-'30). After the revolution of 1830 he became the queen's almoner and secretary general of the society of Christian morality. He was the author of several works on bagnios, prisons, criminals, and prison education, and a series of *Voyages* in various European countries for examination of their prisons.

APPETITE (Lat. *appetere*, to desire or seek earnestly), in physiology, the natural desire and

relish for nutritious food. The desire for food returns, in man and animals, with a certain degree of regularity, at periodical intervals. This is owing to the continuous alteration and waste of the ingredients of the animal tissues and fluids by the active powers of life, and is an indication that the time has arrived for the ingestion of food to reestablish the equilibrium between nourishment and disintegration, and thus maintain the integrity of the vital powers. The healthy appetite, in persons taking a proper amount of exercise, is the best guide for determining the frequency with which food should be taken, as well as for its quantity, and the kind of food consumed. If not satisfied within a reasonable time, the appetite becomes at first imperative and distressing, and is then apt to fail altogether; so that the desire for food disappears until the next recurrence of its habitual period of return. A morbid appetite, or a craving for food in unnatural quantity or of unnatural character, is sometimes a well marked symptom of disease.

APPIAN (Lat. *Appianus*), a Greek historian of the 2d century, born at Alexandria in Egypt. He removed to Rome in the reign of Trajan, and continued there under Hadrian and Antoninus Pius. He was by profession an advocate, and at Rome filled the office of procurator, and had charge of the imperial treasury. He wrote a Roman history in 24 books. Eleven books of this history, together with some fragments, have come down to us. His style is unaffected, and his work, though disfigured by blunders, is highly important as a repository of information. The best edition of his remains is that of Schweighäuser (3 vols. 8vo, Leipsic, 1785).

APPIANI, Andrea, an Italian painter, born at Bosisio, near Milan, in 1754, died in 1817 or 1818. His best works are frescoes in the palace at Milan and the cupola of Santa Maria di San Celso. "Apollo and the Muses" in the Villa Bonaparte is also an admirable specimen of his style. Napoleon and most of the members of the imperial family sat to him for their portraits. An attack of apoplexy in 1813 rendered him so helpless that he was obliged to sell his drawings and other valuables, and he died in poverty.

APPIANO, the name of an Italian family which ruled over Pisa and Piombino from the 14th to the 17th century. **I. Jacopo I.**, the founder of the family, died Sept. 5, 1398. Having attached himself to the Ghibelline party, he conspired with Galeazzo Visconti, sovereign of Milan, excited in 1392 a commotion in the streets of Pisa, during which he effected the massacre of the chief magistrate, Pietro Gambacorti, and his two sons, and in the midst of the popular consternation assumed the title of sovereign of Pisa. **II. Gherardo**, son and successor of the preceding, sold Pisa to Visconti, duke of Milan, for 200,000 florins, reserving to himself only the sovereignty of Piombino and the isle of Elba, whither he withdrew in 1399. His descen-

dants of the male line preserved for two centuries the principality of Piombino, after which it was surrendered in 1631 by the emperor Ferdinand II. to Philip IV. of Spain. **III. Jacopo III.**, ruler of Piombino, died in 1474. A conspiracy against him, aided by Galeazzo Maria Sforza, duke of Milan, proved unsuccessful, but Jacopo was obliged to place himself under the protection of Ferdinand, king of Naples. He consented to receive a Neapolitan garrison in Piombino, and in return was permitted to join to his own name that of Aragona. **IV. Jacopo IV.**, son of the preceding, sovereign of Piombino, died in 1511. He married a daughter of the king of Naples, and took a command in the army directed by that prince and by Sixtus IV. against Lorenzo de' Medici. He was taken prisoner by the Florentines and obliged to pay a ransom for his liberty. In 1501 Caesar Borgia took possession of Piombino, but Jacopo was restored by an insurrection of the people.

APPIAN WAY (Lat. *Via Appia*), a celebrated road which with its branches connected Rome with all parts of southern Italy. The main road was laid out as far as Capua by Appius Claudius Cæcus (312-307 B. C.), and was subsequently continued to Brundisium. It was remarkable for its substantial pavement of large and well fitting blocks, and was the most picturesque of all the approaches to Rome. Numerous magnificent sepulchres lined the road, the most memorable of which were those of Calatinus and the Scipios. Until about 20 years ago, the greater part of the road beyond the tomb of Cæcilia Metella, or between the 3d and 11th milestones, was hardly distinguishable from the surrounding campagna, excepting by the ruins of sepulchres; but excavations in 1850-'53, extending over the Appian way from its beginning at the Capena gate as far as the ancient site of Bovillæ, have reopened an interesting part of the road. Cannina, who carried out this work under the auspices of the papal government, describes these discoveries in *La prima parte della Via Appia dalla porta Capena a Boville* (2 vols., Rome, 1851-'53). The restoration of the ancient road is called the *Via Appia Nova*, and passes in a straight line through Albano until it reaches the viaduct, completed in 1853, which spans a deep ravine between Albano and Aricia. The railway from Rome to Naples crosses the Appian way near the 11th milestone.

APPIUS CLAUDIUS. See **CLAUDIUS.**

APPLE, the fruit of *pyrus malus*, of the natural order *rosacea*. Although the apple is mentioned in the Bible, and by Theophrastus, Herodotus, and other ancient writers, it is probable that other fruits were designated by that name. Even now the word apple is used to designate a fleshy fruit, as the love-apple (tomato), pine-apple, rose-apple (*myrtaceæ*). The derivation of the word is curious. Anglo-Saxon *apl* (German, *Apfel*), one of the few names of our common fruits

The Appian Way. (See p. 538.)

not derived from the Latin or French, is, according to Dr. Prior, of common origin with the Zend and Sanskrit *ab* or *ap*, water, and *p'hala*, fruit. The Latin *pomum*, from the root *po*, to drink, would also signify "a watery fruit." Whatever be the parent country of the apple, it was doubtless of eastern origin. Pliny mentions the crab and wild apples as small and sour, so sour "as to take the edge from off a knife;" but some, he says, are remarkable for their "fine flavor and the pungency of their smell." Many varieties were cultivated about Rome, and they usually bore the names of those who originated them or grafted them. More than 20 sorts are mentioned by Pliny, but none of these, if in existence now, can be identified from his brief and imperfect description. Probably the Romans introduced the apple into England as well as the pear, but the early chronicles are silent as to its subsequent history in that country until after the establishment of Christianity, when the monks and heads of religious houses planted orchards, and henceforth the fruit became common. The early settlers of America brought apple trees, and an island in Boston harbor where they were planted still bears their name. The Indians helped to spread the fruit through the country, and "Indian orchards" are common throughout New England. —Whether in the wild state or cultivated, the apple is by no means a handsome tree. The stem is slow-growing, low-branching, with rigid, irregular branches, in many varieties pendent to the ground; the bark after the tree has passed its early youth becomes rough and scaly; the diameter of the head is usually greater than its height, which seldom exceeds 30 feet; the leaves are broad, tough, and rigid,

those of sweet-fruited trees being usually of a darker green; the blossoms are generally tinged with red and are sweet-scented; the fruit is more or less depressed at the insertion of the peduncle; woody threads (10) pass through the fruit, being regularly disposed around the 2-5 carpels, which contain two seeds each. The apple tree is very tenacious of life, many specimens bearing fruit in this country at an age of nearly 200 years, and the best artificial varieties last from 50 to 80 years. Various species of the genus *pyrus* grow spontaneously in Europe; the *P. malus* is found as far north as 60° in western Russia. In the United States, the *P. coronaria* or American crab apple is abundant in the middle states and southward; it is about 20 feet high, and the blossoms, which appear in May and are large, rose-colored, and sweet-scented, are followed by a greenish-yellow fragrant fruit about an inch in diameter. The apple does not grow well in warm climates, and although cultivated in China and India, it is only in the cooler and mountainous parts that it lives long, and the fruit is less abundant and inferior in quality. In the Hawaiian islands the apple trees planted some years ago seem to have entirely changed their habit of growth, and send up long, vertical, almost branchless shoots. Wherever the apple occurs in its truly wild state, it is usually armed with thorns while young.—New and choice varieties of apples are obtained by planting seed, as about one in 10,000 of the resulting trees will prove better than the original, and a desirable kind once obtained may be continued by grafting or budding. In culture deep limestone lands are the best, as indicated by the analysis of apple wood and bark by Prof. Emmons, who found in 100 parts of

the ashes of sap wood 16 parts potash, 18 lime, 17 phosphate of lime; in 100 parts of the ashes of bark, 4 parts potash, 51 lime. The young trees should be planted in holes of considerable size and depth, setting the tree at the same depth it was in the nursery, taking care to replace none of the barren subsoil, and covering the surface of the ground with a mulching to retain water or liquid manure, which may then be applied without danger of caking the earth about the rootlets. The distance between trees should be from 25 to 40 feet, according to variety, some spreading much more than others. Usually in New England the trees are planted too closely; and the system of lining the stone walls with these trees has much to commend it, as the walls retain moisture and also allow the leaves and snow to drift and accumulate at their sides, thus supplying needed nourishment to the trees; and, moreover, as the rocks wear away they replace the potash in the soil, or, if it be a limestone rock, the limestone which the tree so much needs. Apple trees will not grow well in wet soil, nor where the sod surrounds them; the ground should be stirred up about the trees and well manured with plaster or animal manures, as indicated by the soil, for several years after planting. Alkaline washes on the trunk will preserve the even green bark until the tree is 10 or 15 years old. The rich soils of the western states yield apples of unequalled size, but the flavor is inferior to those produced on eastern limestone soils, or where the proportion of vegetable matter in the soil is less and that of the red oxide of iron greater. Dwarf apple trees are sometimes cultivated for hedges or ornament, and the Chinese raise the tree in pots. Many varieties grafted on the wild crab do well and are dwarfed; but in Europe the favorite stock for dwarfing is the French paradise apple, a naturally small tree, or the English *douzain*. In England and France the trees are trained on walls, as espaliers and balloon-shaped, to insure ripening; but in the United States no such precaution is necessary. Of ornamental blossoming apple trees, the common crab and the double-flowered Siberian crab, both red and white, are much cultivated.—The wood of the apple tree in its wild state is fine-grained, hard, and of a light brown color; and, in exception to the general rule, the cultivated wood is of a still finer and closer grain, weighing in the proportion of about 66 to 45 of the wild wood. In a green state the wood weighs from 48 to 66 lbs. per cubic foot, and it loses in drying about a tenth of its weight and from an eighth to a twelfth of its bulk. It is much used by turners and for the manufacture of shoe lasts, cogs for wheels, and some kinds of furniture; stained black and polished, it passes for ebony; and the wood of the roots is cut into thin sheets or veneers for interior decorations.—The apple as an article of food is probably unsurpassed except by the banana for its agreeable and nutritive properties. Unlike most tropical fruits,

it requires no training to become acceptable to the palate, and, whether baked, boiled, made into jellies, or preserved with cider in the Shaker apple sauce or apple butter, is popular everywhere. The exportation of New England ice was accompanied by the exportation of New England apples, which are better suited for this purpose than western ones; and at the ice ports of China and India American apples are to be purchased in as fine a condition as in our own markets. American apples always command a good price in England. Every farmer cuts and dries a supply of apples for use in the late spring and early summer, and immense quantities of apples are pared and cut by machinery, and slowly dried in ovens or in the sun, furnishing an important article of trade. The flavor is much injured by long exposure to the sun. When properly prepared, dried apples will remain good for five or six years if kept in a dry place; and for use it is only necessary to soak them in water a short time previous to boiling. Crab apples make the best jelly, and are also much used for a sweet pickle. The *raisiné composé* of the French is made by boiling apples in must or new wine. By mixing the juice with water and sugar a light fruit wine is obtained. Cider in the United States has never acquired much celebrity from the care of its manufacture, as it has usually been made from the refuse of the orchard. That made from wild apples or seedlings is much the best. In England, in the counties of Herefordshire, Worcestershire, and Devonshire, much cider is made of superior quality. (See CIDER.) To these uses of the apple it may be added that a mixture of apple pulp and lard was the original *pomatum*.—The orchard products of the United States (mostly apples) are stated in the census returns for 1870 to be worth \$47,335,189. More than a million acres are under cultivation as orchards, but many more acres of lilly land might be used profitably for this purpose, where no other fruit would grow well. In New England the crop is apt to be irregular, and some years the abundance is so great that the fruit will not pay for picking and sending to market, and is used for cider or to feed swine. The apple tree is not subject to disease, and years ago the fruit was perfectly fair and uninjured by worm or caterpillar in New England, as still in Oregon and the West; but now the borer (*saperda bittata*) attacks the stem, perforating it a little above the ground; the woolly aphid attacks the tender shoots; the caterpillar (*elisiocampa americana*) builds its cobweb nests and devours the leaves; the canker-worm (*anisopteryx venusta*) also devours all foliage; the apple moth (*carposcapa pometaria*) lays its egg at the edge of the calyx, and the larva when hatched enters the fruit; and the bark louse (*coccus*) attacks the bark. The borer may be destroyed, as well as the bark louse and aphid, by potash washes (1½ lbs. of potash to 2 gallons of water), if applied when the egg is unhatched; but after

the borer has entered the stem it may be killed by thrusting a wire into the hole. The apple moth is destroyed by feeding all the fallen apples to swine, thus preventing the larvæ from entering the earth, where they undergo their transformations. The caterpillar comes from eggs laid in the fall on the smaller twigs, encircling them, and, as the whole community collects in the nest, may be burned by torches on poles thrust among the branches. The canker-worm is not so easily managed, from the vast number of its armies. As the females are wingless, they may be prevented from ascending the stem to lay their eggs, when they issue from the chrysalis in the ground at the base of the tree, by tar or any viscid substance that will entrap them, and by digging around the trees in the fall and exposing the pupæ to the weather.—The varieties of apple suitable for growth in different parts of the United States have been made the subject of many experiments by the best pomologists; and the national pomological society, founded in 1850 by the late A. J. Downing and others, has published the results. To these reports and to the publications of local societies cultivators are referred for the best kinds for orchards in their vicinity. For general cultivation, the Williams's favorite, a large red apple, the Porter, Newtown pippin, early bough, red Astrakhan, and Gravenstein are recommended for fall use; while for winter the Baldwin, Rhode Island greening, Danvers winter-sweet, fameuse, Hubbardston nonesuch, northern spy, Spitzenberg, minister, Vandevere, and Roxbury russet offer a variety both for cooking and dessert. Some of these, however, do not flourish in New England; others do not bear well in the western states. For exportation the Baldwin, Rhode Island greening, Newtown pippin, Spitzenberg, and Swaar are most in demand. In the Boston market native apples command a higher price than western ones, although the latter are usually larger and fairer. Apples are commonly brought to market in barrels which weigh about 150 lbs.; and Pliny says that this was one of the two fruits known in his time that could be preserved in casks. On the western coast, however, apples are always marketed in boxes somewhat smaller than standard orange boxes, holding about a bushel.

APPLES OF SODOM, a fruit supposed to grow near the Dead sea, fair to the sight, but when plucked dissolving into smoke and ashes. A general opinion, supported by Hasselquist, is that the "apples of Sodom" are to be found in the fruit of the *solanum melongena* (nightshade), which he describes as filled with dust or ashes; or at least, when punctured by a certain insect, as it frequently is, the whole interior of the fruit is converted into a fine dust, leaving the rind entire in form and color. Robinson, in his "Biblical Researches," identifies the apple of Sodom with the *asclepias gigantea vel procera*. The Arabs call it *osher*. It is found on the shores of the Dead sea, and

Robinson says that seeing the two (the osher and the nightshade) growing side by side, the former struck him at once from its agreement with the ancient story, while the latter did not. He describes the osher as from 10 to 15 feet high, having a grayish cork-like bark, oval leaves, flowers similar to the silkweed of the northern United States, and as discharging like that plant a milky fluid when broken. The fruit resembles an orange in size and color, but, when even very carefully touched, explodes like a bladder or puff-ball, leaving in the hands only a rind and a few filaments by which the interior was traversed.

APPLETON, a city of Wisconsin, capital of Outagamie county, situated on an eminence overlooking Fox river, 30 m. from its mouth, and 5 m. N. of Lake Winnebago, and on the Wisconsin division of the Chicago and Northwestern railroad, 214 m. from Chicago; pop. in 1870, 4,518. The rapids known as the Grand Chute have here a descent of about 30 feet in a distance of 1½ m. The city is the seat of Lawrence university, a Methodist institution, established in 1847, which in 1871 had 9 instructors, 185 male and 87 female students, and a library of 6,000 volumes.

APPLETON, Daniel, the founder of the publishing house of D. Appleton and company, in New York, born in Haverhill, Mass., Dec. 10, 1785, died March 27, 1849. He commenced business as a retail trader in his native place. He afterward removed to a larger business field in Boston, and subsequently to New York. In the latter place he commenced the importation of English books, and in the course of years, by his energy of character, established one of the largest importing and publishing houses in the United States, which is now continued by his sons.

APPLETON, Jesse, D. D., president of Bowdoin college, born in New Ipswich, N. H., Nov. 17, 1772, died in Brunswick, Me., Nov. 12, 1819. He graduated at Dartmouth college in 1792, was licensed to preach in 1795, and in February, 1797, was ordained the pastor of a church in Hampton, N. H., where he remained 10 years. From 1807 till his death he was president of Bowdoin college. In addition to the duties appertaining to his office of president, he was often called upon to preach in the neighboring towns, besides which he preached before the Bible, missionary, and peace societies of Maine, the American board of foreign missions, the Massachusetts legislature, and numerous other public bodies. He was the father-in-law of the late president Franklin Pierce. Two volumes of his sermons, lectures, and addresses have been published.

APPLETON, Nathan, an American merchant and political economist, born in New Ipswich, N. H., Oct. 6, 1779, died in Boston, July 14, 1861. In 1813 he was associated with Francis C. Lowell and Patrick T. Jackson in establishing at Waltham near Boston a cotton mill, in which was set up the first power loom ever

used in the United States. In 1821 he became one of the founders of the Merrimack manufacturing company, from which originated the city of Lowell; and he was the projector and chief proprietor of the Hamilton company. He was distinguished as a steady advocate of the protective system. In 1815 he entered the legislature, and was several times re-elected. In 1830 he was chosen a representative in congress from Boston, and during the first session opposed McDuffie's report on the tariff, in a speech characterized by Mr. Webster as "a model of close reasoning on an abstruse subject." In 1842 he was again elected to congress, and aided in securing the passage of the protective tariff bill of that year; but after the close of a single session he resigned his seat. His little treatise entitled "Remarks on Currency and Banking" (enlarged edition, 1857), has been pronounced "almost worthy of being studied in the schools as an elementary manual." He also published an account of the introduction of the power loom and the origin of the city of Lowell. He accumulated a large estate, and was noted for his integrity and philanthropy.

APPLETON, Samuel, an American merchant and philanthropist, brother and partner of the preceding, born in New Ipswich, N. H., June 22, 1766, died in Boston, July 12, 1853. His opportunities for study were confined to the district schools, and at the age of 17 he became himself a teacher. In 1794 he established himself in trade in Boston. He was for many years a heavy importer of English goods, and at a later period largely engaged in the cotton manufacture. At his death his fortune amounted to nearly \$1,000,000, and he had given away nearly as much as that during his lifetime. He endowed the academy at New Ipswich with a fund which secured its permanence, and founded the professorship of natural philosophy of Dartmouth college, with a gift of \$10,000. In his old age he became more and more absorbed with a desire to relieve the sufferings of the poor, and intrusted physicians and others with large sums for that purpose. By his will he placed property to the amount of \$200,000 in the hands of his executors, "to be by them applied, disposed of, and distributed, for scientific, literary, religious, and charitable purposes."

APPLING, a S. E. county of Georgia, bounded N. and E. by the Altamaha river, and drained by the affluents of the Santilla; area, 1,060 sq. m.; pop. in 1870, 5,086, of whom 976 were colored. It has railroad communication with Brunswick and Macon. The surface is level and sandy. In 1870 the county produced 63,063 bushels of corn, 39,508 of oats, 38,106 of sweet potatoes, 48,500 lbs. of rice, 12,509 gallons of molasses, and 152 bales of cotton. Capital, Holmesville.

APPOLD, J. George, an English inventor, born in 1799, died at Clifton, Aug. 31, 1864. The paying-out apparatus used in laying submarine

telegraphs was chiefly his invention. His centrifugal pumps for drainage purposes attracted much attention at the international exhibitions of 1851 and 1862. In his own house and its surroundings almost everything was automatic, doors and shutters opening and closing mechanically. He had also secured a monopoly as a dresser of furs by a secret process.

APPOMATTOX, a county of Virginia S. E. of the centre of the state, bounded N. W. by the James river, and drained by the sources of the Appomattox; area, 260 sq. m.; pop. in 1870, 8,950, of whom 4,536 were colored. The surface is diversified with ranges of mountains and covered with forests, and the soil is fertile. The county is intersected by the South Side railroad, running from Petersburg to Lynchburg. In 1870 the county produced 33,825 bushels of wheat, 76,708 of corn, 65,858 of oats, and 656,944 lbs. of tobacco. Capital, Appomattox Court House, or Clover Hill.

APPOMATTOX COURT HOUSE, a village, capital of Appomattox county, Va. (locally called Clover Hill), 20 m. E. of Lynchburg. On April 9, 1865, Gen. Lee here surrendered the army of northern Virginia to Gen. Grant. Of this army only 27,805 remained. The rest had been killed and taken prisoners, or had deserted, during the battles around Richmond, and after its evacuation on the 2d. There were delivered 350 wagons, about 10,000 muskets, and 30 pieces of artillery.

APPOMATTOX RIVER rises in Appomattox and Prince Edward's counties, Va., and flows circuitously E. about 120 m. to the James river at City Point. It has a narrow and deep channel, and is navigable for vessels of 100 tons to Petersburg, about 20 m. from its mouth. By a canal round the falls at Petersburg, vessels of four or five tons ascend to Farnville, about 80 m. further.

APPONYI, one of the oldest noble families of Hungary, several members of which have achieved considerable prominence in the Hungarian or Austrian service, among them the following: **I. György Antal**, count, born in 1751, officiated as member of the royal lieutenancy in Buda, and subsequently as lord-lieutenant of the county of Tolna, but chiefly distinguished himself as founder of the Apponyi library, a large and valuable collection, opened to the public in Presburg in 1827, ten years after his death. **II. Antal**, son of the preceding, born in 1782, was equally remarkable as a patron of literature and art and as a diplomatist, serving successively, as a representative of Austria, at the courts of St. James, Rome, and Paris. He died in 1852. **III. Rudolf**, the son of the preceding, born in 1812, chose the career of his father, was appointed Austrian minister at Turin in 1849, transferred to London in 1856, made ambassador there in 1860, and relieved in 1871 by Count Beust, when he was sent by Count Andrassy as ambassador to Constantinople. **IV. György**, cousin of the preceding and grandson of György Antal, born in 1808,

was a conspicuous member of the conservative party at the diet of Presburg in 1843-'4, and became Hungarian court chancellor in 1847. He lived in retirement during and after the revolution of 1848-'9, and accepted in 1859 a position in the wider Reichsrath of Vienna, where he farthered with great energy and ability various schemes for the restoration of the constitution of his country. In 1860 he was made *judez curia*, in 1861 opened as royal commissioner the diet of Pesth, and by his mediatory position was in the following years, next to Francis Deák, the most influential person in bringing about the reconciliation between Hungary and the court of Vienna, which in 1867 culminated in the transformation of the Austrian empire on the basis of nationality and constitutionalism. A leading conservative, Count Apponyi is esteemed by all parties as a patriot and a statesman.

APPRAISEMENT (Lat. *appretiare*, to set a price upon), a valuation of property by persons authorized to make it by the law or by stipulation between the parties. The three principal kinds of appraisement known to American law are: of the inventoried property of decedents and insolvents; of property taken for public use; and of real estate seized upon execution. In some states the creditor may enforce a sale of his debtor's lands without a previous appraisement; in others an appraisement is a necessary prerequisite. In some states land once sold on execution is irredeemable by the debtor; in others he has a right to redeem it within a reasonable period, six months or a year, at the appraised value, with interest. There are states where the creditor has no right to sell upon execution, but may take the property of his debtor in payment so far as it goes, at two thirds of the appraised value; in case of refusal the levy is discharged, and the creditor must pay costs.

APPRENTICE (Fr. *apprendre*, to learn), a person bound to service for a term of years, and receiving in return for such service instruction in his master's business. Apprenticeship had its origin in the system of associated trades which prevailed in almost all parts of Europe in the middle ages. Those only who were free of the fraternity of a trade were allowed to exercise it; and the usual, if not the indispensable, mode of acquiring this freedom was through an apprenticeship to a member of the body, for a time and under regulations varying in different towns and in different trades in the same town. In some instances the rules designed to limit the numbers of the fraternity were so strict as to prohibit the master from taking any apprentice but his own son. In France, the apprentice, after having served in that capacity from three to eight or ten years, served as a journeyman, called the *compagnon* of his master, a number of years more, after which he was entitled to admission as a master into the *communauté* or *corps de marchands*, if the *chef-d'œuvre* which he was

required to deliver to the *jurande*, wardens of the company, showed him to be a proficient in his art. Sons of merchants living with their fathers until they were 17 years old were entitled to the privileges of those who had served their apprenticeship. These companies were abolished at the revolution, but the contract of apprenticeship, although no longer imperative, is still frequently entered into in France, and there are statutes regulating the rights and duties of the parties to it. In Germany, where the system exists to the present day, in a more or less modified and legally limited form, the term of apprenticeship, *Lehrjahre*, is generally about seven years, but sometimes less. The apprentice, after serving for the prescribed term, becomes a *Gesell*, like the French *compagnon*, and is entitled to receive from the guild a general letter of recommendation, armed with which he commences his travels. Being recognized and employed by his brethren of the same craft, he works his way from town to town, and on returning with certificates of good conduct during his *Wanderjahre* is entitled to become a master. In Italy the contract of apprenticeship resembled that in use in England. In Scotland and Ireland the regulations regarding it were never rigorous, and those existing in the latter country were early superseded by English laws designed to encourage immigration.—In the 12th century guilds were formed in England, and shortly afterward, without doubt, apprenticeships came into vogue, although there is no notice of them in the statutes until the year 1388. The London apprentices, many of whom were of high birth or had wealthy masters, formed an important body and figure in history, particularly during the time of the civil wars. The term of apprenticeship was fixed at seven years, which had been the ordinary period of service previously, by a statute passed in the reign of Elizabeth. The institution became so widespread that acts designed to limit the number of apprentices were passed, and the courts showed no favor to the laws which recognized and supported the relation, but restricted their operation to trades existing at the time of their passage; a doctrine which, while giving rise to some absurd anomalies, exempted most of the large manufacturing towns from the operation of the act of Elizabeth. In 1813 numerous petitions for the repeal of this statute were presented, and shortly afterward apprenticeship, as a necessary means of access to a trade, was abolished. The English law on the subject has been revised and settled in the master and servant act of 1867 (30 and 31 Victoria, ch. 141); and in almost all our states the contract of apprenticeship is provided for by express statutes, most of them, at least in the older states, being of an early date. The statutory law of New York had been till 1871 very little changed since the original act of 1801.—The contract of apprenticeship is made between the master on one side and the infant and usually his par-

ent or guardian on the other. It is commonly in writing and under seal, and is to be regarded like any other contract of that sort. It has been said that at common law the infant is bound by an engagement of this sort, because it is an agreement that certainly must be for his benefit. But it is probable that this is not the rule, and that the infant is not bound by his contract of apprenticeship more than he is by any other of his contracts. The statutory law may however declare that he shall be bound in such a case, and it usually does. It has also been held in the United States, though otherwise in England, that at common law the parent or guardian may bind the minor without his joining in or assenting to the articles. But the statutes of almost all our states expressly require the infant's assent. The long existing statute of New York on the subject may be referred to as fairly illustrating the American law on the subject. By that statute, every male infant and every unmarried female under the age of 18 years may with the consent of the proper parties bind himself or herself in writing to serve as clerk, apprentice, or servant in any trade, profession, or employment, if a male till 21 years of age, and if a female till 18 years of age, or for any shorter term; and such engagement is as binding on the infant as if he or she were of full age. The engagement, however, must be with the consent of the father; and by a statute of 1862, if the mother be living, it is not valid without her written consent also. But if the father be dead, or incapable of giving his assent, or have neglected his family, the consent must be given by the mother; or if she be dead, or incapable, or refuse, then by the legally appointed guardian; or if there be none, or he be incapable, then by the overseers of the poor or any two justices of the peace of the town where the infant resides. The consent in either instance must be in writing. The executor of a father's last will, who has been directed to bring up the child to some trade or calling, may also bind the infant to an apprenticeship. Superintendents and overseers of the poor of counties, or overseers of the poor of a town, with the consent of two justices of the peace, or of the mayor, recorder, or an alderman, may also bind out children who are charges on a county, town, or city. By recent statutes idle and truant children may also be bound to apprenticeships by similar officers. The age of the infant must be stated in the indentures, and will be taken to be the true age; but public officers authorized to make the contract must inform themselves of the true age fully. Any sum of money agreed to be paid by the master must be mentioned in the articles. If the child is apprenticed by public officers, the indentures must contain an agreement on the part of the master that he will cause the child to be taught reading and writing, and if a male, arithmetic. Any person coming from a foreign country

may bind himself to service—if an infant, until 21 years of age; and if the agreement is made in order to earn the price of his passage money to this country, it shall not be for a longer term than one year, and in this case the indenture must be acknowledged by the apprentice on a private examination before the mayor, recorder, alderman, or justice of the peace. An indenture of this sort may be assigned by the master with the consent of either of these officers. No indenture is valid against the apprentice unless it is made in the manner here prescribed. If the apprentice absent himself from his service, he must serve double time, though not for more than three years beyond the original term. Complaints by the master of the misbehavior of the apprentice are to be heard by certain officers, and the apprentice may be punished by confinement, or in a proper case the officers may discharge the apprentice from his service, and his master from all obligation to him. The apprentice may also be discharged from service by the same officers on his complaint of ill usage by his master; and in such a case the master may be bound over to answer in a court of sessions. The law in these respects is substantially the same in Michigan, Wisconsin, Iowa, and Kentucky as in New York. By a recent statute of New York (1869) all institutions for the reception of minors must, on binding children in their charge to apprenticeships, take bonds to the people, in which the master shall undertake to treat the children kindly. By the statute of New York passed in 1871, it is provided that it shall not be lawful to take as an apprentice any minor without first obtaining the consent of his legal guardians; nor shall any minor be taken as an apprentice unless an indenture be drawn up according to the requirements of the act; and the indenture must be under seal, and signed by the employer, the apprentice, and his parents or parent if living, or if not, then by his legal guardians. The indenture, to be valid, must also contain certain covenants and provisions expressly prescribed by the act. The apprentice shall engage to serve not less than three nor more than five years, and shall also covenant not to leave his master during the term of service. The master must covenant to provide the apprentice proper board, lodging, and medical attendance; to teach him every branch of the business for which he is indentured; and at the end of the term to give him a certificate in writing stating that he has served his full time. Any person taking an apprentice without complying with these requirements is guilty of a misdemeanor and liable to a fine of \$500. No indenture made under the statute shall be cancelled before the expiration of the term except in case of death, or by an order of a court for good cause. If the apprentice leave his employer without his consent or without good cause, and refuse to return, he may be arrested and committed to a jail or house of correction for such term as the

magistrate may think just. If the apprentice refuse or neglect to perform his part of the contract, the indenture may be cancelled for the benefit of the master; and the apprentice forfeits all wages then due him. If the master refuses to perform his part of the contract, the parent or guardian may bring an action for damages against him, and may recover not less than \$100 nor more than \$1,000, to be paid to the apprentice or to his parent or guardian for his benefit. In Vermont minors above 14 years of age may be bound as apprentices by their father or guardian, and the consent of the minor must be attested by his signature to the indentures. The law on this point is similar in Rhode Island, Connecticut, New Jersey, Pennsylvania, Missouri, and other states. In Ohio, if the guardian binds the infant, the court of common pleas must approve the contract.—Among the more important and practical points which have been decided in respect to apprenticeship, it has been held that as the agreement on the part of the master is in the nature of a personal trust, the indenture cannot be assigned by him, at all events not without the infant's consent, or unless, as by the custom of London, such assignment be sanctioned by settled usage. But an assignment without the infant's consent, though it do not bind him, may hold the master to his own covenants. In some of our states the consent of both father and infant is made essential. The apprentice cannot abandon the service unless his master desert him. Nor is the apprentice's misconduct in general a defence for the master in an action against the latter on his covenants. For though one may dismiss a mere servant for misconduct, a master cannot turn away an apprentice for ordinary misbehavior, such as idleness or drunkenness; but he may discharge him for theft or for any wilful injury. Illness of the apprentice does not discharge the master; and in a recent case in Massachusetts the father recovered full wages for the whole period of the apprentice's last illness and up to the time of his death. The master is also bound to provide proper medicines and care for the apprentice in case of his sickness. If the apprentice run away and go into another person's service, the master is entitled to recover the full value of his labor, without deduction of the wages paid the apprentice by his new employer. The master has also an action for the value of the apprentice's services against any one who entices him away, or wilfully harbors him after his desertion, with a knowledge of the apprenticeship. Though the master may chastise the minor as a parent may, yet he cannot authorize any one else to inflict the punishment; and it has been held in New York that whipping the apprentice for absenting himself at a trial where he was required as a witness, was assault and battery. Where an apprentice was bound to the master and his executors, they carrying on the same business, it was held that the widow, who was executrix and continued

the master's business, was bound to instruct the minor, and he was bound to render her service. As the infant is not bound at common law by his covenants, it is usual to take security from some responsible person for the performance of the contract by the apprentice; and in such a case the surety must be a party to the articles. The contract is dissolved by consent of all parties. The death of the master also discharges the obligation of the apprentice, and so does his bankruptcy or insolvency, or his abandonment of the business in which he agreed to instruct the apprentice.

APRAXIN. I. Fedor, a Russian grand admiral, born in 1671, died Nov. 10, 1728. He was one of the leading men of the reign of Peter the Great, and is especially remarkable as the creator of the Russian navy. During the war between Sweden and Russia he expelled the Swedes from Ingria, in 1710 conquered Viborg in Finland, and when war with Turkey broke out, in 1711, he commanded in the Black sea. In 1713 he attacked Finland from the sea, and devastated the shores of Sweden, destroying hundreds of villages, and many towns and iron works. He accompanied Peter in his warlike expedition against Persia, and served on the Caspian sea. He always enjoyed the entire confidence of Peter, though firmly opposed to his reforms, and more than once implicated in extensive malversations. II. Stefan Fedorovitch, a relative of the preceding, died Aug. 31, 1758. When young he served in the army of Münnich against the Turks, rose rapidly, and, returning to the court of the empress Elizabeth, distinguished himself by his decided opposition to the policy of the king of Prussia and his diplomatic adherents, including Count Lestocq, the favorite of the empress. At the beginning of the seven years' war Apraxin, with the rank of field marshal, commanded an army against Frederick the Great. In May, 1757, he invaded Prussia, took Menel, advanced into the interior, destroying everything, and on Aug. 30 won the battle of Gross-Jägerndorf against the Prussian general Lehwald. Instead, however, of marching on Berlin, to which capital the road was open, Apraxin retreated to Courland, having, as it is pretended, received news of the sickness of the empress Elizabeth, and having conspired with the grand chancellor Bestusheff to raise to the throne her grandnephew Paul, over the head of his father, Peter III. After the empress recovered, Apraxin was tried by court martial, but died in prison before the trial ended.

APRICOT (old Eng. *apricock*, Fr. *abricot*, Ger. *Aprikose*; probably from Lat. *arbor præcox*, early tree), the fruit of *prunus Armeniaca* or *Armeniaca vulgaris*, of the order *rosaceæ*. It is a small, rapidly growing tree, attaining to the height of 20 to 30 feet, with a somewhat spreading head, the leaves heart-shaped, smooth, and shining. The flowers are usually white and appear before the leaves—indeed, blossoming before any other fruit tree in the early spring. The fruit seems to be intermediate between the

peach and plum, having the outside of the former and the stone of the latter. The tree is a native of Armenia, and also of the Caucasus, Cabool, the Himalayas, China, and Japan, and by cultivation has been introduced throughout the temperate zone. The tree was cultivated by the Romans, and is mentioned by both Pliny and Dioscorides. The Roman generals introduced it into Gaul and Britain, although the first notice that has been found of its being in England is by Turner, whose "Herbal" was printed in 1562. There it seldom ripens its fruit unless trained against a wall. In California vast quantities are raised, of a large size and fair quality, ripening before the peach. In its wild state the fruit is small, of a waxen yellow color, rosy-cheeked, and of a pleasant, slightly acid flavor. It is dried in large quantities in the East under the name *nishmish*, and the preserved apricots of Damascus are favorably known to all travellers, and sometimes imported into the United States. The

Apricot—Fruit, Flower, and Pit.

best varieties are the Moor Park and the Brussels and Breda, the last two being especially adapted to the confectioner's purposes. The Siberian apricot is cultivated for its foliage and flowers. The chief enemies of this fruit in the United States are a species of curculio, which causes the early dropping of the immature fruit; the black wart, which attacks the branches; and another fungus which destroys the leaf. Apricots are seldom seen in the New England markets, and they are by no means common in New York.

APRIES (Eg. *Uahprahet*, the sun enlarges his heart), a king of Egypt of the 26th dynasty, the Hophra of the Bible, and the Uaphris of Manetho, succeeded his father Psammis (Psamatik II.) about 588 B. C. He invaded Syria, besieged Sidon, and fought a naval battle with the king of Tyre, but failed in his attempt to save Zedekiah from Nebuchadnezzar, who subsequently invaded Egypt. Apries was still

more unfortunate in a war against Cyrene, and perished soon after, according to Herodotus, by a revolt of his subjects, who raised Amasis by the throne (about 569 B. C.).

APRIL (Lat. *Aprilis*), the 4th month of the year, consisting of 30 days. With the Romans it was the 2d month of the year. Julius Cæsar added the 30th day to it. In the time of Nero it was called Neroneus. The name is supposed to be derived from *aperire*, to open, because the buds open themselves at this period. In the Athenian calendar, the latter portion of Elaphebolion and the greater part of Munychion correspond to April. Charlemagne, in his new calendar, called it grass month, the name still given to it by the Dutch (*grasmaand*). The French revolutionary calendar merged it into the greater portion of Germinal and the commencement of Floréal. On antique monuments Aprilis is represented as a dancing youth with a rattle in his hand.—The custom of sending people on empty errands on the 1st of April (hence called All Fools' Day) is common in every country of Europe. Oriental scholars say that it is derived from the *huli* feast among the Hindoos, where a similar custom prevails. Another opinion is that it comes from a celebration of Christ's being sent about to and fro between Herod, Pilate, and Caiaphas. In France the fooled man is called *poisson d'avril*, meaning a silly fish, easily caught. In Scotland he is called *gowk*, which means a cuckoo.

APTERAL (Gr. *à* privative and *πτερόν*, wing), an architectural term used particularly with reference to the temples of the ancient Greeks and Romans. It is applied to buildings which have no lateral columns, but may have porticoes of columns projecting from their ends.

APTERYX, a struthious bird of New Zealand, called by the natives *kiri-kiri* from its peculiar cry. It belongs to the family which contains the living cassowary, emu, mooruk, and ostrich, and the extinct *apornis*, *dinornis*, and *dodo*. The beak resembles that of a long-billed wader, being slender, with the base covered with a bony cere, the upper mandible the longer and containing the openings of the nostrils near the tip; the base of the bill is furnished with long, slender black bristles, intermixed with the feathers, and projecting in all directions; the wings are 2 small crooked appendages, extending about 1½ inches from the sides of the chest, and terminated by a curved, obtuse, horny claw 3 lines long, having 9 quill plumes differing but little from those of the body; the tail is not apparent; the tarsi are as long as the middle toe, covered with variously sized scales, and very robust as in gallinaceous birds; there are 3 anterior toes, free and covered with scales, and a very short hind toe, all armed with strong and rather sharp claws. The plumage is loose as in other terrestrial birds which have no power of flight, resembling that of the emu in size, structure, and color, but wanting the accessory plumelet; the skin is very tough, a line thick along the back,

and there is a large amount of fat between it and the muscles, especially on the back, abdomen, and root of neck; the head is broad and but slightly depressed. The genus *apteryx* was established by Shaw in 1812 from a stuffed skin, and was at that time supposed to have become extinct like the dodo; but in 1833-'8 other specimens arrived, which are described by Mr. Yarrell in vol. i. of the "Transactions of the Zoological Society of London," and by Prof. Owen in vols. ii. and iii. of the same work.

Apterix australis.

Three species are described. *A. australis* (Shaw) is about 30 inches long from tip of bill to end of toes, 19 inches to end of coccyx, and weighs about 3½ lbs.; the bill varies in length from 4½ to 6¾ inches, the longest belonging to the females, another anomaly in this bird; the bill is 1 inch wide at the gape and 7 lines high; the color is grayish brown, darkest on the back. *A. Mantelli* (Bartlett), described in 1850, is about 23 inches long, with a bill of 4 inches; the color is dark rufous brown, darkest on the back. *A. Oweni* (Gould), described in 1847, is the largest species, and is said to be about 3 feet high; the upper parts are transversely barred with blackish brown and fulvous, and the plumage is exceedingly dense and hair-like, resembling more the covering of a mammal than a bird; the bill is an inch shorter, more slender, and curved; the wings are exceedingly rudimentary. The large size of the unhatched young, and the possession within the egg of the remarkable characters of feet, wings, and beak of the adult, show that the young apteryx must be able to provide for itself very soon if not immediately after leaving the egg. The bill of the apteryx is moderately strong, as the bird is said to be in the habit of resting the head upon it against the ground, and to thrust it into the soil in search of food; it is struthious in structure, and grallatorial only in its length and slenderness. There is no trace of extension of air cells, as in birds of flight, into the interspaces of the abdominal viscera, and the diaphragm is well developed and pierced only for the oesophagus and vessels; the lungs are bird-like, and also the organs of circulation, except in the more membranous character of the right auriculo-ventricular valve; the larynx and trachea are

struthious. The bones are not perforated for the admission of air.—These birds are found in New Zealand, particularly in regions covered with extensive and thick beds of ferns, in which they hide when alarmed. They are nocturnal in their habits, feeding upon snails, insects, worms, and the large soft-bodied lepidopterous larvæ; they run swiftly and defend themselves vigorously with the feet. The nest is made either at the base of a hollow tree or in deep holes which they excavate in the ground. The natives pursue them for their skins, which from their strength are highly valued for making dresses.—Though a living specimen has been seen at the zoological gardens in London, the apteryx is probably nearly extinct; the *teporinis* is supposed to be extinct, though some believe that it may yet exist in Madagascar; the dodo has been lost within the memory of man; and the *dinornis* doubtless antedated the historic period.

APULEIUS, or *Appuleias*, a Roman satirist, born at Medaura in Africa about A. D. 130. By his mother he was a descendant of Plutarch. After studying at Carthage, he began to travel for the purpose of learning philosophy and religion. Coming to Rome, he was obliged to sell his clothes in order to obtain the sum necessary for his initiation into the service of Osiris. He soon repaired his fortune by marriage with a rich widow in Africa, whose relations instituted legal proceedings against him, alleging that he had used magic to win her property and affections. But in his defence Apuleius satisfied the judges that a widow of 14 years' standing needed not the constraint of magic in taking a husband younger than herself. The most celebrated of the numerous works of Apuleius is the "Metamorphoses, or the Golden Ass," a philosophical romance, written, according to Warburton, to ridicule Christianity. But the more probable design of the author was to show, under the guise of allegory, that a voluptuous life leads to bestiality, from which a man can be lifted only by cultivating virtue and religion. The justly famous tale of Cupid and Psyche forms an episode in this work. His writings on ethics and metaphysics are a good epitome of the works of Plato; but the development of that philosopher's more profound doctrines was reserved for subsequent inquirers. The best edition of Apuleius is by Hildebrand (Leipsic, 1842). An English version appeared in London in 1853. "The Golden Ass" has also been translated by T. Taylor (London, 1822) and Sir G. Head (London, 1851).

APULIA, a division of ancient Italy, comprising nearly all that territory now included in the provinces of Capitanata and Terra di Bari, near the S. E. extremity of the peninsula, bounded by the Adriatic, Messapia or Calabria (Terra d'Otranto), the gulf of Tarentum, Lucania, and Samnium. At a remote period the Greeks called the whole southeastern part of Italy, including both these divisions and other

territory, by the name of Japygia, after Japix, the son of Dædalus. This district was inhabited by three tribes, the Messapians or Salentini in Messapia, the Peucetii in the region near the Aufidus (Ofanto), and the Daunians further north. The Romans, however, ignoring these divisions, called all the region, except Messapia, Apulia. The Apulians first appear in history as concluding in 326 B. C. a treaty of alliance with Rome against the Samnites, which they soon after repudiated, thus becoming involved in war with the Romans. In 317 all the Apulian cities submitted to Rome. It was the chief theatre of the most important part of the second Punic war, and the battle of Cannæ was fought within its borders in 216. Many Apulian cities made common cause with Hannibal, but were severely punished on their recapture by Romans. A great portion of Apulia again turned against Rome in the social war, but was subjugated and harshly punished by C. Cosconius in 89. The province appears to have suffered so severely from the conflicts carried on within it, that from this time it declined in wealth and prosperity; and little is said of it until its union, under Augustus, with Calabria (in the ancient meaning of the term) and the territory of the Hirpini, the three forming the "second region" in that emperor's division of Italy. The Hirpini were afterward transferred into the "first region," Calabria and Apulia forming one province, down to the fall of the western empire. The Byzantine emperors regained control of it in the 10th century, after its possession had been long an object of contention between the Lombards, Saracens, and themselves, and held it under a viceroi called a *catapan* until it was conquered by the Normans in the 11th century, who made it a duchy, Robert Guiscard, their leader, becoming its first duke. His son Roger united it, as well as Campania and modern Calabria, with his kingdom of Sicily. The modern name of part of the territory, *Capitanata*, is a corruption of *Catapanata*, from *catapan*. The principal cities of ancient Apulia were Teanum, Luceria, Arpi, Salapia, Canusium, Venusia, and Barium. The district is by the Italians called Puglia, but not officially.

APURE, a river of Venezuela, has its sources in Colombia, in the eastern chain of the Andes, flows between the provinces of Varinas and Apure in an E. N. E. direction, receiving the waters of the Portuguesa, Guarico, and other affluents from the north, flows then E. S. E., and unites with the Orinoco, of which it is an important tributary, in lat. $7^{\circ} 40' N.$, lon. $66^{\circ} 45' W.$ According to Humboldt, its mean descent is about 14 inches to the mile; but the current in the lower part of its course is hardly perceptible, and any rise in the waters of the Orinoco causes it to overflow its banks. The lands thus overflowed yield, after the water has retired, a rich and excellent pasturage.

APURIMAC, a river of Peru, which rises in lat. $15^{\circ} 21' E.$, lon. $72^{\circ} 10' W.$, not far from

the sources of the river Camana, in a lake situated between spurs of the mountains of Caylloma. It flows N. for a short distance, then N. N. W. for about 165 m., receiving several other streams, to its junction with the Mantaro in lat. $12^{\circ} S.$, and from that point is known as the Tambo as well as the Apurimac. Hence it flows first N. E., then N. N. W. for more than four degrees of latitude nearly parallel with the Urubamba, and they unite and form the Ucayali in lat. $8^{\circ} 30' S.$, lon. $73^{\circ} 24' W.$ The Apurimac and the Urubamba collect the moisture of the high plateau of the interior of Peru, and are among the largest tributaries of the Amazon, the former being sometimes reckoned its source.

AQUA (Lat. water), a favorite prefix of the old alchemists to various fluid mixtures, as *aqua fortis*, now called nitric acid; *aqua regia*, the mixture of nitric and muriatic acids, used to dissolve gold, the king of the metals, now called nitro-muriatic acid, or nitro-chlorhydric acid; *aqua vite*, now alcohol. *Aquamarine* is an old name given to a fine variety of beryls from the color resembling the green of sea water.—The *aqua* of the pharmacopœia consist of water holding volatile or gaseous substances in solution. Those which receive a name from some volatile vegetable substance, as *aqua cinnamomi* or *aqua camphora*, contain very much less of the active ingredient than the corresponding tinctures.

AQUA TOFANA (Ital. *acqua della Toffanina*), a secret poison employed in Italy during the latter part of the 17th century, and said to have been invented by a woman named Tofana, a native of Sicily, who lived for a time in Palermo, and subsequently in Naples, where she exercised her criminal art on a large scale. Her customers are said to have been chiefly young wives who wished to be rid of their husbands; and when the number of mysterious deaths about the year 1659 at last aroused suspicion, a secret society of young married women was discovered, presided over by a creature called La Spara, who had learned the art of poisoning from Tofana. La Spara and several others were executed. Tofana was thrown into prison, but the date and manner of her death are uncertain. According to Labat, a French traveller, about 1709 she was seized in a convent in which she had taken refuge, and having, on being tortured, confessed 600 poisonings, she was strangled in prison. On the other hand, Keysler, a German traveller, says he saw her in prison at Naples, a little old woman, in 1730. The poison was put up in small phials, labelled "Manna of St. Nicholas of Bari," with an image of the saint on one side. Incredible and contradictory accounts are given of its nature and effects; it is most probable that it was essentially a strong watery solution of arsenic obtained by long boiling. The use of such an article, even in the dose of five or six drops, frequently repeated for a length of time, would cause death with many of the symptoms ascribed to the aqua Tofana.

AQUARIANS, or *Hydroparastatae*, a sect of ascetics in the early Christian church who, from scruples against the use of wine, were in the habit of consecrating water for sacramental purposes. It was founded in the 2d century by Tatian, a disciple of Justin Martyr.

AQUARIUM, or *Aquavivarium*, a term applied to certain artificial arrangements for the exhibition and study of living animals and plants inhabiting either fresh or salt water. To Mrs. Power, a lady of French descent, belongs the credit of first adopting the aquarium as an aid to scientific research. This intelligent and enthusiastic naturalist, during the year 1832, began the study of the fishes and algae off the coast of Sicily, by transferring them to glass tanks in which the water was often renewed; and this renewal or revivification of the water was long regarded as essential to the health and vigorous growth of the inmates, it being argued that as the air is contaminated by the breathing of animals living upon the surface, and its oxygen is combined with the carbon furnished by the organic body, so the air contained in the water is consumed by administering to animal life, and the gaseous product is not only unfit for longer sustaining this, but, unless removed, proves fatal to it. But subsequent investigations into the various phenomena of vegetable and animal growth have determined that it is the office of plants to restore to the atmosphere the oxygen, and absorb the excess of carbon; and it appears that the subaqueous vegetation fulfils the same office in preserving the purity of the air in the water, upon which depends the life of the animals it contains; and that this balance may not be destroyed by the presence of poisonous gases, the results of decomposition and decay, it was found needful to add certain animals which feed on decomposing vegetable matter, and act as the scavengers in this community. Such are the various species of the molluscous animals, as the snails. It is also of importance to guard against the preponderance of animal life in these artificial tanks or jars; for although there can hardly be too many plants for the health of the animals, as long as they grow healthily and do not decompose, yet an excess of animals over plants will disturb the balance, and lead to the destruction of the former. *Valisneria spiralis*, various species of *chara*, *anacharis alsinastrum*, *stratiotes aloides*, *callitriche autumnalis* or *vernalis*, *ranunculus aquatilis*, and *myriophyllum spicatum* are among the fresh-water plants adapted to this purpose.—The fresh-water aquarium is more easily constructed and requires less skilful management than the marine tank. It should be square or hexagonal, as curved surfaces distort the forms of the inmates, and a greater number of sides increases the liability to leakage. Where metal corner posts are used, they should be plated if possible, as the oxidation of the metal often results disastrously. The glass plates should be held in position by hy-

draulic cement; that known as Scott's is highly recommended. Where putty only is available, it should be painted, the tank filled with water for a week or more, and then carefully cleaned before receiving the fishes and plants. The bottom should be covered to a depth of an inch or more with well washed river sand, and its surface thickly strewn with pebbles; clay or mould should be avoided, both because of the vegetable germs it may contain, and because its frequent disturbance by the fish renders the water turbid. The use of tastefully arranged rockwork adds greatly to the beauty; but rocks containing metallic substances should be rejected; and where shells are used, they should first be well soaked or calcined in order to destroy all organic matter contained in them. In constructing these arches or columns Portland cement may be used to advantage, and some point of the structure should project above the water level. Thus arranged, the tank, which should be at least 12 inches deep, may be filled with fresh spring or river water to within an inch of the top, and it is then ready for occupation. Such fresh-water plants as the *butomus*, *nymphaea*, and *alisma* should

Fresh-Water Tank.

have their fibrous roots extended and gently imbedded in the sand, with a layer of pebbles to keep them in position. All river plants that bud and root from points on the stem, as *anacharis*, *ranunculus*, *callitriche*, and *chara*, can be raised by securing them in tufts to the sandy bottom by a light layer of pebbles. There are certain plants which, in addition to beauty of structure and vigorous growth, are of great service as oxygen producers; such are the *valisneria spiralis*, water thyme (*anacharis alsinastrum*), with the flowering water crowfoot (*ranunculus aquatilis*), milfoil, and starwort.—Though the stocking of the aquarium depends largely upon the purpose it is to serve, yet caution is needed as to the number and habits of the inmates. A young pickerel only an inch and a half long has been known to devour 25 minnows in a week. For general interest, the stickleback takes the lead among the fishes, and for beauty the gold fish, tench, gudgeon, perch, minnow, and Prussian carp all flourish, with snails and mussels as purifiers. Where the proper balance is not easily maintained

and the renewal of the water is difficult, it may be revived by dipping out and pouring back in a small stream from a proper height. As in the marine tank, an excess of sunlight is apt to encourage the growth of a minute green fungus, besides unduly elevating the temperature, which should range between 40° and 60° F.—The marine tank, owing to its greater range, and the extreme sensitiveness of its animals and plants, requires more constant and careful management. As a rule it should be more shallow. To secure this, and also obtain sufficient depth of water for fish and hardy plants, a tank having its back and two ends opaque has been successfully adopted, in which case there may be of the same material as the bed plate—marble, slate, or well seasoned wood. The front is of glass, and the bottom an inclined plane rising from the lower corner in front

Marine Tank, Front View.

Marine Tank, Side View.

to above the water level behind; on this rest the rock and shell work. The triangular space between the front and this plane may be filled to the depth of an inch or two with sand and gravel, with a sprinkling of the same among the rocks and shells above. The purpose of this sloping floor is to afford the anemones, actiniae, &c., which move seldom and slowly, to approach the surface and recede from it at pleasure. Marine plants purify sea water, as fresh-water plants purify fresh water. The difficulties of maintaining the balance are, however, greater in sea-water artificial tanks than in fresh-water; but by care in selecting seaweeds, avoiding those which are large and throw off much matter from their surface, and not overcrowding the water with animal life, tanks containing marine aquatic animals and plants can be easily managed. Species of *porphyra*, *chondrus*, *crispus*, *iridea edulis*, and the *deles-*

seria are recommended.—Where vegetation is only needed for the production of oxygen, Mr. Shirley Hibberd, the author of a useful handbook on the aquarium, recommends the encouragement of confervoid growth; and where sea water is used, the germs contained in it will soon, under the light and warmth of the sun, develop into a vigorous and serviceable vegetation. This, together with certain animalcules that, contrary to rule, are also oxygen producers, will be all that is needed to preserve the desired balance. The absence of direct sunlight and the presence of the *buccinum* or sea snail both serve to keep in check that fungous or mucous growth which would otherwise obstruct the vision. The fishes and crustaceans and molluscous animals should be introduced by degrees, with proper regard to maintaining the due balance of vegetable and animal life. Those which appear to thrive best are minnows, sticklebacks, shrimps, small lobsters, hermit crabs, eels, and star fishes. The *patella* or limpet, *purpura* or whelk, the top, the winkle, and several varieties of *crepidula* also do well. The more delicate sea plants, with the various forms of actiniae, should be secured if possible attached to their native bed, as removal from it is hazardous.—The best position for either tank is between or at the side of windows, so as to avoid the direct rays of the sun. Marine animals and plants are extremely sensitive to atmospheric changes, and the salt water, which should not vary far from 60° F., should also have a specific gravity of 1.028 at this temperature. As in the fresh-water aquarium, regard must be paid to the habits and tastes of the inmates, lest the stronger overcome the weaker. All save the fishes may be best transported in damp seaweed, care being taken to pack securely and transfer rapidly. Where sea water cannot be obtained, a mixture of common salt 81 parts, Epsom salts 7 parts, chloride of magnesium 10 parts, and chloride of potassium 2 parts, may be dissolved in pure water until its gravity reaches 1.028 at 60° F. The animals should be fed twice a week with finely cut fresh mussels, oysters, or raw beef; and in case of the mollusks, actiniae, &c., the food should be brought within reach by means of a small glass rod. Decayed vegetation or putrid animal matter must be quickly removed. When the supply of oxygen is limited, the fishes will approach the surface often to breathe.—The first aquarium having for its aim the instruction of the people was erected in the gardens of the zoological society, Regent's park, London, in 1853. It was made up of 25 glass tanks, 6 feet in length and 30 inches in depth and width, lining the interior of a crystal building 60 by 25 feet. The success of this effort prompted the crystal palace aquarium company to erect their building, which was opened to the public Aug. 22, 1871, at Sydenham. This mammoth aquarium with its adjuncts is nearly 400 feet long and 70 broad.

It is situated at the northern end of the palace, and is one story high, with a reservoir beneath the main saloon containing 80,000 gallons of sea water, and the tanks above 20,000 gallons—in all, 100,000 gallons, weighing 1,000,000 lbs. Eighteen tanks with plate-glass fronts range along the left of the grand saloon, separated from the wall by a narrow passage, and a row of 21 shallow tanks, the inmates of which are held as a reserve force. To the right are two small rooms with 9 shallow tanks each, in which the view is from above only; here the light is better suited to the growth of the sensitive rhodospirms (red algae). The 18 large tanks range in capacity from 4,000 gallons in the centre to 400 on the ends of the line. The water is elevated from the main reservoir through double sets of vulcanized rubber pipes, and discharged into the two central tanks at an average rate of 6,000 gallons an hour, the stream diverging north and south and passing through the main line into the reserve and side tanks, and thence returning to the reservoir. Independently, however, of the simple fall of water from one tank to another in steps of from 3 to 6 inches in height in the series 1 to 18, other streams of water, mixed with great quantities of air in minute bubbles, are driven from the main pipe into all the tanks with force, through jets; so that myriads of such bubbles, controlled by stopcocks, are forced in a state of fine division (resembling falling sand, or steam) nearly or quite down to the bottom of each tank, and thus the fluid is charged with as much atmospheric air as it will take up in open vessels. The quantity of seaweed necessary to decompose the poisonous carbonic acid gas evolved from the animals, which could not be effected

by mechanical agitation, is grown upon the rocks of the aquarium by the action of light on the spores of algae existing invisibly in the water. These tanks contain at present 95 distinct forms of marine life. A description of this work appeared in "Nature," vol. iv., p. 469. There are extensive aquaria in the principal continental cities of Europe, those of Naples, Brussels, and Berlin being the largest.—For instructions as to the management of the aquarium, Gosse's "Handbook of the Marine Aquarium" (London, 1854), and Hibberd's "Book of the Aquarium" (London, 1856), are safe and serviceable guides. See also Rossmässlér's *Das Süßwasser-aquarium* (Leipsic, 1851).

AQUEDUCT (Lat. *aquæ*, of water, and *ductus*, a channel; formerly spelled *aquæduct*), a channel for the conveyance of water, or, in the more general acceptation of the word, a structure raised above the surface, upon which water conduits are laid. Methods of supplying water which do not include such structures are commonly called water works. The use of these conveyances for water to supply cities may be traced back to a very remote period in Persia and in Judea. The "pools of Solomon," near Bethlehem, were three large reservoirs connected with each other, from which water was conveyed to Jerusalem, 6 m. distant. One of these pools was 582 ft. long, and, at an average, about 180 wide. Jerusalem is still supplied with water from them through a 10-inch earthen pipe. In Egypt and Babylonia similar works were constructed in very early ages. Enough remains of the ancient aqueduct of Carthage to show that it was one of the most remarkable of these great works; upon it the waters from the mountains of Zeugis were conveyed through an arched conduit 6 ft. wide

Ruins of the Aqueduct of Carthage.

and 4 ft. deep. The whole length was 70 m. The ruin here illustrated is that of an arcade near Undena, composed of 1,000 arches, many of which were over 100 ft. in height. In its construction hydraulic cement was largely used, which is at present so solid that a single piece over 100 feet in length has fallen from the top without being broken. The ancient city of Mexico was supplied with water by the aqueduct of Chapultepec, built by Montezuma, and carried across the lake upon a causeway. But no aqueducts, ancient or modern, equal in length or in expense of labor those constructed by the incas of Peru. To irrigate their sterile soil, they brought water from the reservoirs of the mountains several hundred miles off. The aqueducts passed along the precipitous sides of the Andes, penetrating some by tunnels worked through the solid rock with-

out iron tools, and crossing chasms upon walls and arches of solid masonry. The conduit was constructed of large slabs of freestone, which were closely fitted together without cement. The works have long since fallen to ruins.—The Romans, however, exceeded all other nations, ancient and modern, in the construction of these works. A treatise *De Aqueductibus Urbis Romæ* was written by the consul Sextus Julius Frontinus, who had the direction of the aqueducts under the emperor Nerva. He refers to nine different aqueducts, which brought into the city daily 28,000,000 cubic feet of pure water. The number of these was afterward increased to 24, some of which had several channels placed one above another, and extending many miles. They were built on a grade of regular descent, winding around the hills or penetrating them by tunnels, and in the low

Ruins of the Aqua Claudia.

levels supported on arches, which sometimes, as in the New Anio, extended for $6\frac{1}{2}$ m. in one continued series, many of the arches more than 100 ft. high. The whole length of this aqueduct was over 63 miles. The Aqua Martia, which extended 38 miles, contained nearly 7,000 arches. The conduits were constructed in brick or in stonework laid in cement. There were numerous openings for ventilation and cisterns for collecting the sediment, in consequence of which the water was very pure. The Aqua Julia and Aqua Tepula were conveyed into the city upon the same structure, though at a higher level. The Aqua Claudia took its rise 38 m. from Rome, and approached it by a circuitous route, being led under ground $36\frac{1}{2}$ m. and along 7 m. of cut stone arcades of sufficient height to supply the hills of Rome. The capacity of all the aqueducts was wonderful in proportion to the population. Strabo said that whole rivers

flowed through the streets of Rome. It is estimated that 50,000,000 cubic feet of water must have been supplied daily to a population of 1,000,000, or about 312 imperial gallons to each individual. This is about ten times the supply from the three aqueducts at present in use. The Romans built other aqueducts also in their provinces, some of which exceeded in grandeur those which supplied the capital. That of Metis (Metz) in Belgic Gaul is among the most remarkable. Extending across the valley of the Moselle, it conveyed the waters of the river Gorse to the city in such quantity that from it basins were filled in which mock naval engagements took place. The ruins of this great work still remain. There may also be cited the aqueducts of the island of Mitylene, of Antioch, of Segovia in Spain, and of Constantinople. The aqueduct of Antioch was supplied from Beit el-Ma, 6 m. distant. The illustration given is that

of a portion of one of the main bridges, 700 ft. long and 200 ft. high. Though solidly built, it is yet the rudest example of Roman work, and

not compelled to do so from ignorance of other methods. Prof. Leslie obtained a lead pipe supposed to have been used at the baths of Caracalla; and Delorme states that the waters from Mount Pila crossed three valleys through inverted syphons. The water was collected in a reservoir upon one hill and conducted through nine lead pipes $8\frac{1}{2}$ in. in diameter and $1\frac{1}{2}$ in. thick down the hillside, thence along an arcade 80 ft. high, and up the opposite slope, where it was discharged into a second reservoir. It is estimated that the lead alone used in these three inverted syphons would now be worth \$2,500,000. In modern aqueducts the system of gradual descent is only partially followed, the use of cast-iron pipes admitting of frequent changes in the inclination.—In the reign of Louis XIV. an aqueduct of vast expense was constructed for supplying Versailles with water. The bridge of Maintenon, built for supporting this aqueduct, is about 4,400 ft. or $\frac{3}{4}$ of a mile long, upward of 200 ft. high, and is constructed of three tiers of arches, 242 in each tier, and of a span of 50 ft. The aqueduct for supplying Marseilles is a canal 60 m. long. It passes through several chains of limestone mountains by 45 tunnels, the united length of which is $8\frac{1}{2}$ m., and across a ravine 5 m. from Aix by a structure of masonry 262 ft. high and 1,287 ft. long. The quantity of water that flows through it is 198,000 gallons per minute. The Lisbon aqueduct, completed in 1738, is about 3 leagues in length, and in some parts of its course has been excavated through hills; but near the city it is carried over a deep valley for a length of 2,400 ft. by several bold arches, the largest of which has a height of 250 ft. and a span of 115 ft.—The Croton aqueduct of New York surpasses all modern constructions of this

Aqueduct of Antioch.

contrasts strangely with the bridge of the aqueduct of Nîmes, or Pont du Gard, across which the waters of the river Hure were led. This bridge spanned the valley of the river Gard

Pont du Gard, Nîmes.

by a triple row of arches, the first six having a span of 60 ft. each; above these were 12 similar ones; while the upper row was composed of 36 smaller arches arranged as in the illustration, the whole forming one of the finest examples of Roman architecture. In 1740 the engineer Pitot built a roadway beside this aqueduct and level with its lowest tier of arches. The aqueduct of Spoleto is of uncertain origin. One of the bridges is 810 ft. long, and the main arches are 240 ft. high. This work remains entire. Though the Romans constructed their aqueducts so as to obtain a gradual descent, it is evident that they were

Croton Aqueduct, crossing Mill River.

kind in extent and magnificence. It was completed in 1842, having been five years in building, under the superintendence of Mr. John B. Jervis, chief engineer. The whole expense,

including \$1,800,000 for distributing pipes, and amounts paid for right of way and other incidental charges, was \$10,375,000. Including commissions and interest, the whole cost was \$12,500,000. The whole length, from its source at Croton river to the distributing reservoir on 5th avenue and 40th street, is 40½ m. On this line are 16 tunnels having an aggregate length of 6,841 ft., and cut mainly through gneiss rock. A large part of the open cutting is also rock work. A dam constructed across the Croton river raised the water 40 feet, and formed the Croton lake, which covers about 400 acres. This is the collecting reservoir, and contains with a depth of 6 ft. of water 500,000,000 gallons. A new collecting reservoir is (1873) in course of construction at Boyd's Corners, Putnam county, to be formed by building across the west branch of the Croton river a dam 700 ft. long and of sufficient height to secure a storage capacity of 3,000,000,000 gallons, flooding over 300 acres of land. From

springing line of the arch, and 8 ft. 5½ in. high; area of cross section, 53½ sq. ft. In rock tunnels the roofing arch is dispensed with, though the bottom and sides are as here described and illustrated. Its capacity is equal to 115,000,000 gallons daily. The inclination is 1.1088 ft. per mile, or 33.92 ft. in the 33 m. The velocity of the water is 1½ m. an hour. Across Harlem river the aqueduct is carried upon the High bridge in two cast-iron pipes of 3 ft. diameter, and one wrought-iron pipe 7 ft. 6 in. in diameter, recently laid over the former. The lower pipes are 12.29 ft. lower than the bottom of the conduit on the N. side of the river, and 10 ft. below the aqueduct on the S. side. While the bridge was building, the water was conveyed in a 3-foot iron pipe down one bank of the river and up the other, and the original intention was to have had this for the permanent plan. Objections being raised that the pipe would obstruct the navigation of the river, and restrictions being imposed by the state legislature as to its use, it was finally decided to build a bridge with arches 80 ft. wide and openings 100 ft. high, to admit the passage of vessels. The bridge, as now completed, is 1,460 ft. long, with 8 arches in the river of the required span, and 7 others on the banks of 50 ft. span. The whole height of the bridge above high-water mark is 116 ft. There are two receiving reservoirs in the Central Park, known as the old and the new. The former covers an area of 35 acres and has a capacity of 500,000 gallons; the latter 100 acres, with a capacity of 1,170,000 gallons. From these reservoirs to the distributing reservoir, a distance of 2¼ m., or directly into the city, the water is conveyed in two lines of iron pipe 30 in., two lines 36 in., and one line 48 in. in

Rock Tunnel

Main Aqueduct.

the dam to the Harlem river, nearly 33 m., the aqueduct is built of stone, brick, and cement, arched over and under, 6 ft. 9 in. wide at the bottom (this being the chord of an arc, the versed sine of which is 9 in.), 7 ft. 5 in. at the

High Bridge, Harlem River.

diameter. The capacity of this distributing reservoir is 20,000,000 gallons. It is a stone structure 45 ft. high above the streets, and 425 ft. square at the top, covering a little more than four acres. The higher sections of the island lying north of Manhattan valley are supplied from a reservoir and tower lately erected on the high ground near 173d street, between 10th avenue and the aqueduct. The water for the supply of this high service reservoir and the adjacent tower tank is furnished by two pumping engines stationed near the lower end of the high bridge. (See WATER WORKS.) In 1871 the average daily demand was 85,000,000 gallons, which is taken mainly from the distributing reservoir and conveyed through the city in 340 m. of iron pipe ranging in diameter from 4 ft. to 4 in.—The cities of Brooklyn and Jersey City receive their water supply, the former from several ponds from 8 to 14 m. distant, and the latter from the Passaic river, 8 m. distant. In both cases the water enters the city upon such a level as to require the use of pumping engines for its distribution. For the plan and capacity of these engines, as also of those in operation at the famous Fairmount water works, Philadelphia, see WATER WORKS. The aqueduct which supplies the city of Boston leads from Cochituate lake to the receiving reservoir at Brookline, a distance of 14½ m. For the greater part of the way it is a conduit of brick masonry. Over the valley of Charles river is a line of iron mains, and in Newton and Brookline are two tunnels. The brick conduit winds by irregular curves along the country, and is of such an elevation as admits of the work being mostly beneath the natural surface. The brickwork is 8 in. thick, laid in hydraulic cement, the section of the conduit being that of an egg, the larger end down. The greatest

Cochituate Aqueduct.

width is 5 ft. and the extreme internal height 6 ft. 4 in. This aqueduct is everywhere covered by at least 4 ft. of earth, and nowhere admits of a passage underneath, except by culverts at the crossing of Charles river and at a bridge over a valley in Needham. The two 30-inch iron pipes cross the river upon a stone bridge at a level 71 ft. above low-water mark. The whole length of each pipe is 979 ft. The tunnels are in porphyritic rock of great hardness, one 2,410 and the other 1,150

ft. in length. The city of Washington is supplied with water through an aqueduct constructed by the national government, 18 m. long, leading from the Potomac falls to the receiving reservoir at Chain Bridge. On the line of this work are 11 tunnels and 6 bridges; the chief of these, over Cabin John creek, is a stone structure 100 ft. high and having a single span of 220 ft. The whole cost of the work exceeded \$3,000,000. The Chicago lake tunnel, through which the waters of Lake Michigan are led into that city, was commenced March 17, 1864, and completed under the supervision of city engineer E. F. Chesborough, March 8, 1867. (See TUNNEL.)—Though the Croton aqueduct is at present the greatest work of its kind in the United States, others have been projected which, if brought to successful completion, will far surpass it. Among these is the plan of supplying the city of San Francisco from Lake Tahoe, a mountain reservoir of great depth and purity, located upon the boundary line between California and Nevada, and distant from San Francisco about 150 m. It is also now proposed to construct an aqueduct from Lake George to the city of New York, a distance of over 200 m., the conduit to be of sufficient size to supply the many cities and villages along the route.—In addition to the structures mentioned above, there are numerous bridges designed for the conveyance of canals across rivers and valleys. The first of these canal aqueducts built in England was constructed by the architect Brindley, under the supervision of the duke of Bridgewater. Upon it the Lancaster canal crossed the river Lune. It was composed of 5 arches of 72 ft. span each, with an average height of 65 ft. above the level of the river. The Forth and Clyde canal crosses the valley of Kelvin upon an arcade somewhat higher, though of not so great length as that across the Lune. The Pont-y-Cysyllte aqueduct conveys the waters of the Ellesmere canal across the vale of Llangollen in Wales. This bridge is 1,000 ft. long, built with 19 arches, each having a span of 45 ft. The canal level is 126 ft. above that of the river below. In the United States there are many structures of this character, those on the Erie canal alone numbering 32. The chief of these are the two crossing the Mohawk river, the Richmond aqueduct over the Seneca river, and the stone arcade across the Genesee at Rochester. The larger of the two Mohawk bridges, crossing the river at a point 14 m. N. W. of Albany, consists of a wooden trunk resting upon 29 stone piers; it is 1,300 ft. long, and cost \$331,000. The Richmond aqueduct is a beautiful stone structure 894½ ft. long, the water being also conveyed in a wooden trunk. For beauty and strength, however, the aqueduct bridge across the Genesee river at Rochester deserves special mention. It is a solid stone structure 920 ft. long, supported upon 6 cut stone arches of 52 ft. span. It is in the centre of the city, and was erected at a cost to the

state of \$500,000. At Pittsburgh, Pa., the Pennsylvania canal is conveyed across the Alleghany river upon a wire suspension aqueduct, having 7 spans of 160 ft. each from pier to pier.

AQUILA, a fortified city of Italy, capital of the province of Abruzzo Ulteriore II., on the Aterno, 56 m. N. E. of Rome; pop. about 12,000. It was built by the emperor Frederick II. in 1240, from the ruins of the ancient Amiternum, the birthplace of Sallust. It was much reduced by earthquakes in 1688, 1703, and 1706. It has a large number of churches and monastic houses.

AQUILA, Kaspar, a German reformer, who thus Latinized his name ADLER, born in Augsburg, Aug. 7, 1488, died in Saalfeld, Nov. 12, 1560. He studied theology in Germany and Italy, became chaplain of Franz von Sickingen, and in 1519 was imprisoned by the bishop of Augsburg for preaching and writing in favor of Lutheranism, and was released only on the interposition of the queen of Denmark. He passed several years in Wittenberg as a preacher and teacher, and in assisting in Luther's translation of the Bible. His publications against the Interim, *Christliches Bedenken auf das Interim* and *Das Interim illuminirt* (1548-'9), caused the emperor to offer a high price for his capture.

AQUILEIA, a village of the Austrian Coastland, circle of Görz, a few miles from the Adriatic and from the Italian frontier. It occupies a portion of the site of ancient Aquileia, a city founded about 182 B. C. by the Romans at the E. extremity of Transpadane Gaul, as a defence against the northern barbarians; or possibly somewhat earlier by the Gauls, in which case, however, it soon fell into the hands of Rome. It is said to have derived its name from *aquila*, an eagle, which appeared as a favorite omen to its founders. It was a powerful military post in the time of Cæsar. In Strabo's time it was the great emporium of Roman trade with Rhetia, Noricum, Pannonia, Istria, and Dalmatia, roads running from the town into those countries. Maximin laid siege to Aquileia, but, failing in the attempt to take the place, he was slain by his own soldiers, A. D. 238. In 452 it was taken by Attila, and razed to the ground; its inhabitants fled to the lagoons on which Venice now stands. It was afterward retaken from the Huns by Narces and partly rebuilt. It was an important episcopal see, and several councils were held there. The bishops of Aquileia assumed in the 6th century the title of patriarch, and for several centuries carried on a contest with the popes, who in opposition to Aquileia established the patriarchate of Grado. The patriarchate of Aquileia was not abolished till 1751. In the middle ages the place gradually dwindled down to a state of entire insignificance.

AQUINAS, Thomas, a saint and doctor of the Latin church, surnamed the Angelic Doctor, born according to some authorities at Aquino in the kingdom of Naples in 1224, according to

others at Belcastro in 1226, died at the Cistercian abbey of Fossa Nuova, in the Pontine marshes, March 7, 1274. His father was count of Aquino, and allied both by blood and marriage with several of the royal families of Europe. At an early age he was intrusted to the care of the Benedictines at Monte Casino, and thence he was transferred to the university of Naples. From the first he showed an inclination to the monastic life, and in 1243 he received the habit of the Dominicans. His relatives were opposed to this proceeding and imprisoned him in a tower of his father's castle, whence, by the help of one of his sisters whom he had converted, he escaped, and was allowed to resume in peace his convent life. In company with the general of the Dominican order, he went to Cologne, where he became a pupil of Albertus Magnus. The nickname of Dumb Ox, which his fellow students gave him from his size and silence, gave occasion to his master one day to exclaim when the promptness and acuteness of his answers had astonished them all, "This dumb ox will give such a bellow in learning as all the world shall hear." In 1248 Thomas was appointed to teach ethics at Cologne; and four years later he was teaching theology at Paris. His school was thronged with students, and crowds waited upon his preaching. In 1261 he was recalled by Urban IV. to Italy, and became a constant attendant and friend of this most active of popes, teaching in the more important places of central and southern Italy, particularly in Naples, Rome, Bologna, and Pisa. He was on his way to the council at Lyons, to sustain the cause of the Latin against the Greek church, when he was seized with his fatal illness. Less than 50 years afterward, in 1323, he was canonized, and the day of his death was appointed as the day of his festival. He is ranked with the four great doctors of the western church. The works of St. Thomas have always had high authority, and large use is still made of them in Catholic theological study. They form 17, 19, and 20 folio volumes, in the various editions from 1490 to 1745. The three volumes of the *Summa Theologie* may be regarded as the most finished compend of scholastic divinity.—See "Life and Labors of S. Thomas of Aquinas," by Roger Bede Vaughan (2 vols., London, 1872).

AQUITANIA, the southwestern division of ancient Gaul, situated between the Garonne, the Pyrenees, and the bay of Biscay. It was the smallest of the earlier divisions of Gaul, and Augustus, in order to equalize it in some measure with the other two, extended its frontier to the Loire. The language, institutions, and physical conformation of the Aquitani were different from those of the other inhabitants of Gaul, and proclaimed their affinity with the Iberian tribes of the Spanish peninsula. Aquitania, or Aquitaine, was an independent duchy under the Merovingian and Carlovingian dynasties, though Charlemagne reduced

it to temporary subordination. By the marriage of Louis VII. with Eleanor of Aquitaine, it became united to the French monarchy in 1137; but 15 years later the same princess, having been divorced from Louis, married Henry Plantagenet (afterward Henry II. of England), and transferred the possession of Aquitaine to her new husband. The title to the duchy was disputed by England and France for many years, but Charles VII. finally reunited it to the French crown in 1453. In the 13th or 14th century the name became corrupted into Guienne. (See GUIENNE.)

ARABELLA STUART. See STUART.

ARABESQUE, a kind of ornamentation, either sculptured or painted, which was at first a characteristic of Moorish architecture, but has in modern times been largely used in decorations of every style. It consists of fantastic combinations of flowers, fruits, branches—of almost any graceful and beautiful objects which

may be intertwined with one another in a variety of forms, or in constant repetitions of a single pattern. The Alhambra, as the best preserved specimen of Moorish architecture, is

particularly rich in arabesques, and those here illustrated are taken from its walls. Raphael employed arabesques in the ornamentation of the Vatican, and of late years Kaulbach has often used them in fresco painting; while in the ordinary decoration of rooms and buildings they have become one of the most common methods of embellishment.

ARABGIR, Arabgheer, or Arabkir, a town of Asia Minor, in the cyalet and 102 m. E. S. E. of Sivas, on the caravan road from Aleppo to Trebizond; pop. about 30,000, one fourth of whom are Armenians, and the rest Turks and Turcomans. The prosperity of the town is due to the caravan trade and to the cotton industry of the Armenians. Fruit trees surround the town, especially the white mulberry, whose fruit is eaten fresh and also used for making brandy and sweetmeats. Wheat is successfully cultivated, and iron ore abounds in the surrounding highlands.

ARABIA (by the Arabs called *Jeziret el-Arab*, the island or peninsula of the Arabs), a peninsula forming the S. W. extremity of Asia, between lat. 12° 40' and 34° N., and lon. 32° 30' and 60° E., bounded N. by Palestine, the Syrian desert, and the Euphrates, E. by the Euphrates, Persian gulf, and gulf of Oman, S. by the Indian ocean and the straits of Bab-el-Mandeb, and W. by the Red sea, the gulf of Suez, and northern Egypt. It is about 1,500 m. in length from near Anah on the Euphrates to the straits of Bab-el-Mandeb, and 900 in breadth from Suez to Bassorah. The S. coast is 1,200 m. long. Area estimated at somewhat more than 1,000,000 sq. m. Its northern limits can hardly be defined with accuracy, owing to the fact that the vast arid deserts of Syria and Arabia blend into each other without any distinct landmarks. Burekhardt represents the boundary as extending from the shores of the Mediterranean near El-Arish along the southern border of Palestine and the Dead sea, thence winding across the Syrian desert to Palmyra, and crossing in a straight line to the Euphrates at Anah. The ancient geographers divided Arabia into three parts. Arabia Petraea or the Rocky occupied the mountainous tract between Palestine and the Red sea; Arabia Deserta or the Desert extended eastward and southward from Petraea to the Euphrates and the Persian gulf, comprising the great desert; and Arabia Felix or the Happy occupied the shores of the Red sea and the Indian ocean. These divisions, however, have always been unknown to the inhabitants themselves. The modern divisions are: 1. The Bahr el-Tur Sinai or Sinaitic peninsula of Petermann, the El-Iladjr of Von Hammer, comprising the small peninsula between the Mediterranean and the two northern arms of the Red sea, and corresponding very nearly to the Arabia Petraea of Ptolemy. 2. Hedjaz, or the land of pilgrimage, commencing S. of the above, extending along the Red sea to the parallel of 19°, and bounded E. by the great central desert. It is a barren district, consisting of sandy plains toward the coast and rocky hills in the interior; the inhabitants depend for a livelihood mainly on the gains from Moslem pilgrims. Some places, as Wady Fatimeh and Taif, are well watered and produce grain and vegetables. The chief commercial ports and cities are Jiddah and Yembo, and the two sacred cities of Mecca and Medina are also in this division. The viceroy of Egypt is nominally the ruler of this territory, but the Beled el-Haram or holy land proper, including the two sacred cities, is under the peculiar jurisdiction of the sherif of Mecca. The Howaitat Arabs, a fierce and dangerous tribe, control the coast from the 25th parallel northward. 3. Yemen, occupying the remainder of the Red sea coast, and forming part of Arabia Felix. It comprises the finest and most fertile portion of the peninsula. Toward the sea the soil is scorched and barren, but the interior is a high-

land country, of precipitous though fertile hills, and a healthy climate. Its extent is about 30,000 sq. m., and it is governed by several petty sovereigns or chiefs. Its principal towns are Sana, Mocha, and Loheta, and it is in this province that the celebrated Mocha coffee is raised. The stronghold and port of Aden, an Asiatic Gibraltar, now belonging to Great Britain, is in this district. The Tehama is a sandy belt extending along the Red sea nearly from Akaba to Aden, and stretching backward to the mountains, varying in breadth from 30 to 60 miles. It bears many marks of having anciently formed part of the bed of the sea, and various marine fossils are to be found in the soil. As the sea gradually recedes and leaves the coral banks exposed, these are soon filled up by the sands. This tract is of no service to man; it contains vast strata of salt, and the sandy soil is wholly incapable of cultivation.

4. Hadramaut, forming the great southern portion of Arabia. It extends along the Indian ocean from lon. 45° to $54^{\circ} 30'$, and stretches far into the interior. The mountains on the coast, brown and bare, rise in several ranges behind each other to the height of 1,000 or 1,500 feet, intersected by well watered and fruitful vales. Beyond is the Dahna or great sandy desert, which covers the greater portion of central Arabia. Hadramaut contains about 20 towns; its harbors are Makalla, Dafar, Merbat, and Hasek. The inhabitants are a thriving and commercial people, and the country was formerly famous for producing frankincense.

5. Oman, occupying the tract lying between the Persian gulf and the Indian ocean, and having for its western boundaries the district of Hadramaut and the great central desert. It is a very mountainous region, and toward the sea presents the same appearance as Hadramaut. It is divided among several petty chiefs, the most powerful and enlightened of whom is the imam of Muscat, as he is called by English and Americans, but whose proper title is sultan of Oman. His efforts to extend the commerce of his country with foreign nations have given him considerable reputation. He claims the greater part of the seacoast. Between Oman and Hasa is a tract called Menasir and the cape of Katar. This portion is dreary, sun-scorched, and nearly destitute of vegetation. The bay of Bahr el-Banat, on which it borders, contains the best and most copious pearl fisheries in the Persian gulf, and is a source of considerable wealth to the inhabitants.

6. El-Hasa or Ahsa, extending along the W. coast of the Persian gulf, between Katar and Irak Arab, and the Euphrates. It is partly mountainous and partly level. This district is subject to occasional shocks of earthquake, and almost all the springs are warm with a slightly sulphurous taste, and the rocks are of tufa and basalt. A bath was built at one of these hot sulphur springs and frequented by invalids for many years; but when the country fell into the hands of the Wahabees,

they destroyed it from superstitious motives. The products of Hasa are fine wool, cotton, rice, wheat, dates, sugar cane, and almost all the leguminous plants. Cloaks, shawls, gold lace, swords, and daggers are manufactured here. The chief towns are Hofhuf and Katif. The Wahabee chieftains have greatly reduced the commerce and manufactures of Hasa by drafting merchants and artisans into their army.

7. Nedjed or Nejd, the central and largest of the divisions of Arabia, is traversed from N. E. to S. W. by a range of mountains, forming a plateau about 3,000 feet above the level of the sea. This plateau is intersected by numerous fertile valleys, bordered by steep and often precipitous banks; in these are built the villages and towns. In the E. part of this region iron ore is found in considerable quantities; and in the west, in Jebel Toweik, are both iron and copper. The best breed of Arabian horses is produced in Nedjed. Riyad is the capital of the Wahabee monarch. Nedjed is separated from Hasa by a tongue of the Dahna, the great desert. The monarch or chief of Nedjed has subjected Hasa on the east, lower Kasim on the northwest, and the surrounding Bedouin tribes. The population of Nedjed and Hasa, including the Bedouin tribes, is computed at about 1,300,000.

8. Shomer, consisting of three mountain ranges running N. E. and S. W. nearly parallel to each other, Jebel Adja, Jebel Selma, and upper Kasim. These, with lower Kasim, which belongs to the chief of the Wahabees, are separated from Nedjed by a strip of desert. Between these mountain ranges extend broad plains covered with grass and shrubbery, which afford excellent pasturage for cattle. Grain, dates, and other fruits are raised in the mountains, and water can be found almost everywhere by digging a few feet beneath the surface. Hayel, the capital, is a walled and fortified town of about 20,000 inhabitants, situated almost in the heart of the province. It has of late years distinguished itself by encouraging commerce, subduing the marauding Bedouin tribes around, and rendering travel more secure. Another wide expanse of sand lies between Shomer and Wady Jowf and Wady Serhan on the north, the former a fertile valley and the latter a barren sandy depression. Both are under the jurisdiction of the prince of Shomer. Beyond this commences the Syro-Arabian desert. West of Nedjed and Shomer is another expanse of desert that separates these two districts from Hedjaz and Yemen. The more habitable parts of the Syro-Arabian desert are occupied by various Bedouin tribes—the Beni Lam on the east, and the Howeitat, Sherarat, and the Edwan (once a very powerful tribe, but now greatly reduced in numbers) on the west. Von Hammer adds to these two other divisions: Esh-Shehr, or Mahra, E. of Hadramaut proper, a dreary region, but containing some well cultivated and well inhabited districts, and occupied by a people whose language differs materially from the modern Arabic; and El-Yama-

mah, the S. E. portion of Nedjed, bordering on El-Iladjar, Oman, and the great desert. The latter has been designated above as the district of Katar and Menasir, famous for its pearl fisheries.—The S. and S. E. portions of Arabia consist of an immense waste of sandy desert, the Dahna or Robat el-Kholy, “the abode of emptiness,” which covers about one third of the entire peninsula. The sands, generally of a reddish color and thrown up into mounds by the winds, present to the eye the appearance of a fiery sea suddenly solidified. There is a very strong resemblance, in almost every particular, between the Arabian desert and the African desert of Sahara. Ophthalmia is common in Arabia, owing probably to the irritation produced upon the eye by the glare of the sand, and its almost constant presence in the atmosphere. A species of leprosy known as Arabian elephantiasis is also prevalent, and is attributed to the bad quality of food and water. The plague has occasionally visited the coast, but never penetrated into the interior. A remarkable phenomenon in the central portions of Arabia, especially those bearing evidence of volcanic action, is the sand gulfs described by Baron von Wrede. These are large pits filled to the brim with a whitish impalpable powder. Von Wrede cast into one of them a sea lead, which sank so rapidly that he was obliged to let go the line, which, though of considerable length, instantly disappeared.—Palgrave is of opinion that the watershed of central Arabia bears from N. N. W. to S. S. E. between lon. 45° and 46° E. and lat. 29° and 24° N. Its greatest altitude is behind Jelajel in the province of Sedeyr in Nedjed, whence it gradually declines till lost in the southern desert. On each side of this ridge to the south also Arabia slopes coastward to the Persian gulf, Indian ocean, and Red sea, though with some local interruptions. The Sinaitic peninsula is traversed by spurs from the Lebanon range. Mt. Seir and Tur Sinah (supposed to be Mt. Sinai) are its principal summits. Of the many islands which border the coast, the Bahrein isles in the Persian gulf and Socotra in the Indian ocean are the only important ones. Arabia has no considerable river. Its streams, taking their rise in the mountains, lose themselves for the most part in the sands, or form deep ravines called by the natives wadys; they reach the sea only when swollen by the rains. The Schan and the Kebir flow into the Red sea; the Meitan and the Moseira into the Indian ocean. Several of these are said by recent geographers to pursue a subterraneous course, for which the dense clay which underlies the sand, and the cavernous limestone, afford facilities, and to discharge into the sea at some distance from the shore. A recent German traveller relates that at certain points near the coast the sailors would spring overboard with their goat skins, and diving down would bring up fresh water from springs below the surface of the sea. In many parts little or

no rain falls throughout the year. On the W. coast rains are periodical, occurring from June till September. On the S. and E. coasts, on the contrary, they occur during the winter months.—In the desert the thermometer is generally above 100° F. during the night, 108° in the morning, and in the course of the day it rises to 110° and sometimes higher. The climate of Mecca is sultry and unwholesome; at Medina it is much colder in winter and hotter in summer. At Mocha it averages from 90° to 95° in July; in Muscat from 92° to 102° during the day. In Petraea the diversity is much greater, the maximum in the upper regions being 75° in May, and in the lower country, particularly on the seashore, 102° to 105° , and sometimes 110° . In the desert, near the Euphrates, Griffith observed that it rose to 132° under his tent and to 156° when exposed to the sun's rays.—The mountains consist of porphyry, jasper, quartz, sand-stone, alabaster, basalt, marble, and limestone. The minerals are blue alabaster, agates, carnelians, tourmalines, the emerald, the onyx, gypsum, saltpetre, sulphur, naphtha, asphaltum, iron, lead, and copper. Gold was formerly obtained in Yemen, but the supply has long been exhausted. Mines of iron, lead, copper, and rock salt are still worked.—Although but a small portion of Arabia is susceptible of cultivation, its vegetable productions have always been greatly famed. The date and other species of palm stud the oases of the desert. In Yemen the coffee tree yields the small Mocha berry. The balm tree (*ancyris opobalsamum*), which furnishes the fragrant balm of Mecca, the *acacia vera*, which produces the gum arabic of commerce, the *cassia fistula* or purging cassia, the aloe, and the *olibanum* or frankincense, are the most valuable of the products of the soil. The durra (*sorghum vulgare*), a species of millet, which furnishes the chief article of food to the village Arabs, the sugar cane, wheat, barley, beans, rape, lentils, melons, gourds, oranges, lemons, pears, quinces, apricots, almonds, peaches, grapes, tamarinds, and coconuts form the bulk of the other productions of the country. The methods of agriculture adopted by the Arabs are extremely rude, but owing to their industry, and the porous and friable character of the soil, which only needs water to make it yield abundantly in the more fertile regions, they succeed in raising very good crops. In many parts of Yemen ploughing is not attempted, but the ground is cultivated with a crowbar and hoe, as substitutes for the spade. Throughout nearly the whole country which is under cultivation, artificial irrigation is practised. At Muscat wheat and barley are sown in December and reaped in March.—The horse is supposed by some to have originated here. The camel and the dromedary are natives of the Arabian deserts. The ass also originated in this country, and the onager or wild ass, though perhaps a different species, still roams in the deserts of Nedjed. There is

a race of oxen with a hump on the shoulders. The broad, thick-tailed sheep is common, but its wool is coarse, and its flesh not delicate. Among wild animals, the rock goat or ibex, gazelle, antelope, and jerboa are very abundant; and in the interior the hyena, panther, ounce, jackal, wolf, fox, wild boar, and wild cat exist. There are many species of apes, some of which cause great damage to the coffee plantations of Yemen. Among rapacious birds are found one or more species of the eagle, falcon, heron, owl, and ostrich. The partridge, guinea fowl, and pheasant are also found in different districts of the country. Fish abound on all the coasts, and on that of Oman the *pinna marina*, or pearl oyster, is found in large quantities. Reptiles are very numerous, including tortoises, many species of lizards (some of which, like the *guaril*, are of great size, and are used for food), serpents, and batrachians. The locusts often destroy the crops, and many other insects inflict serious injury upon men or animals.—For many centuries the Arabians monopolized, in connection with their neighbors of Phœnicia, the greater part of the carrying trade of the world; and even when the Venetians, Portuguese, and Dutch had entered into competition with them, they still retained the trade between India and Europe. The doubling of the Cape of Good Hope by the Portuguese was the signal for a rapid decline in their commerce; but the opening of the overland passage to India in recent times gave it a new impulse. The principal exports of Arabia are coffee (much of which is brought to Muscat, Mocha, and Jiddah from Abyssinia, Nubia, and Egypt, and exported thence as genuine Mocha coffee), dates, gum arabic, myrrh, aloes, almonds, balm of Mecca, frankincense, some aromatic and medicinal drugs, and pearls. The traffic in pearls is almost entirely in the hands of the banians, or Hindoo merchants. From Muscat, wheat, horses, raisins, salt, dried fish, and drugs are also exported. Arabia receives from Europe silver, iron, copper, lead, firearms, and gunpowder; from Abyssinia, slaves, sheep, elephants' teeth, and musk; from the E. coast of Africa, gold, slaves, amber, and ivory; from Egypt, rice, lentils, sugar, and oil; from Surat, linen; and from Coromandel, cotton.—The population of the Arabian peninsula has been variously estimated at from 10 to 15 millions. The latter is probably the nearest to the truth, as recent explorations demonstrate that the interior contains more fertile lands and a denser population than was formerly supposed. It is estimated that the various races and tribes known collectively as Arabs comprise nearly seven eighths of this population; the remainder consists of Hindoos, Turks, negroes, Abyssinians, Jews, Persians, and Franks. Of the settled Arabs there are many distinct tribes, differing so much in manners, habits, and language as to give the impression to the traveller that they originated from different stocks. The discoveries at several points in the

interior of Himyaritic inscriptions, and the existence of a language spoken by the natives of the interior villages called Ehkili, bearing a much stronger analogy to the Himyaritic than to the Arabic, would seem to indicate that a portion of the fixed Arabian population are descendants of those Hamites who originally settled in Syria, Phœnicia, and the adjacent countries. The fixed Arabs are as a general rule, and especially in the northern parts, indolent, improvident, deceitful, treacherous, and prone to robbery. But at the same time they are courteous, sociable, easy in their manners, and intelligent, and the lower classes are superior to those of a corresponding grade in more civilized countries. The Bedouins are, probably with less admixture than the inhabitants of the towns and villages, of Semitic race. They speak the Arabic language with great purity and force, and subsist by rearing cattle and by plunder. (See BEDOONS.)—Mohammedanism or Islamism is the prevalent religion of Arabia, though according to recent travellers the people are generally less devout and more inclined to skepticism than those of any other Mohammedan country; and among the inhabitants of Wady Doan, a large and populous valley in the interior of Hadramaut, Von Wrede found traces of the ancient fire worship; while M. Arnaud in 1843 found among the mountains of Yemen many Arabs whose reverence for Hud, a prophet who preceded Mohammed and who cursed him and his followers, was much stronger than that for the prophet of the Koran.—The Arabs claim descent from Kahtan or Joktan, of the posterity of Noah by Shem, and from Ishmael. Ishmael, according to their tradition, was prince and first high priest of Mecca, and his posterity ruled the city for 14 generations. Joktan or Kahtan was the first king of Yemen. His successors reigned 2,000 years in that country. Saba, the fourth after him, built the capital and called it after his name; hence the Sabæans. He converted one of the valleys in his territory into a large lake, five leagues in length, by constructing a mole or bank across its lower extremity. The water was thence conducted to the fields, gardens, and houses of the inhabitants, and the lands thus irrigated became very productive. Bilkis, one of the queens of Yemen, according to the Arabs, was the famous queen of Sheba who visited Solomon. From her designation queen of the south, and the description of her presents to Solomon, gold and spices, there is little doubt that Arabia, and Yemen in particular, was the native country of this princess. The French traveller T. J. Arnaud, who visited this region in 1843, found among the ruins abundant evidence of its former greatness in the massive blocks of stone covered with inscriptions in the Himyaritic character, and in the ruins of buildings and temples which must have once approached in magnificence those of Palmyra or Tadmor. Himyar, the immediate successor of Saba, is

supposed to have been the founder of the city of Mareb, and to have invented the Himyaritic characters. After an inundation caused by the bursting of the immense reservoir built by Saba the tribes of this kingdom were scattered, and were not again united till a century later under Tobba I., about A. D. 175. Under him and his successors Yemen rose to more than its ancient splendor. Assad Abukarb (220) invaded and subdued Tehama, defeated the Tartars in Azerbaijan, plundered many cities of Khiva, and seems to have carried his arms into Bokhara. Tobba II. in 297 invaded Hedjaz and besieged Yathreb (now Medina), a city inhabited by Jewish refugees after the destruction of Jerusalem. While there he was converted to Judaism, and on his return home all the nation embraced the Mosaic faith. Dunawas in 480 was a furious persecutor of the Christians, and is said to have burned 20,000 of them in a pit filled with combustibles. The Christian king of Abyssinia sent an army under the command of his son Arayat, with orders to slay every Jew and plunder the country. Dunawas was routed, and cast himself into the sea, and the race of the Himyarite princes became extinct. Arayat was confirmed in the government of Yemen, and the Abyssinians ruled it for 72 years, until Seif, a descendant of the Himyarites, obtained from Chosroës, king of Persia, an army with which he wrested the power from the hands of the Abyssinians. He was appointed viceroy of the king of Persia, to whom he paid an annual tribute. After Seif's assassination by an Abyssinian slave, Yemen was governed by Persian satraps under the title of emirs till it was subdued by the lieutenants of Mohammed.—The kingdom of Hira in Irak was founded by some of the dispersed clans after the inundation in Yemen. Numan I., about A. D. 400, signalized himself by his conquests in Syria, building numerous vessels on the Euphrates, and adorning the capital with palaces, gardens, and hunting parks. Numan is said to have become a convert to Christianity and abdicated the throne to live in retirement. Mundar II., who reigned about 493, proved a valuable ally to the Persian monarch Kobad in his successful invasion of the Roman territories. In the reign of Mundar V. (633) the kingdom of Hira was invaded and subdued by the lieutenants of Mohammed. Other colonies of Arabs migrated northward into the territory of Damascus, where they founded a dynasty of kings called the Gassanites. Several small principalities existed in those districts before their arrival, the chief of which was the tribe of Silh, who had become converted to Christianity, in consequence of which the Roman emperor invested them with the government of the Syrian Arabs. These the emigrants (the tribes of Aus and Khasraj) expelled, slew many of their petty princes, and established their own sovereignty over these conquered territories, which lasted for about

400 years, when it was extinguished by Moslem conquests.—The Nabathæan Arabs, or Ishmaelites, long preserved a distinct name as a nation, asserting their independence alike against the armies of Egypt and Ethiopia, of the Jews, Assyrians, Greeks, and Romans. "It was extremely difficult," says Diodorus Siculus, "either to attack or subdue them, because they retired to their deserts; and if an enemy ventured to follow them, he was sure to perish of thirst and fatigue, for the wells were only known to themselves." In the time of the Assyrian and Babylonian empires these wild tribes remained either wholly independent, or acknowledged a temporary alliance with their monarchs. The Medes and Persians under Cyrus and Cambyses found it necessary to have a friendly understanding with the Nabathæans to secure a safe passage into Egypt. In 312 B. C. Antigonus, one of the successors of Alexander the Great, made an unsuccessful incursion into the territory of the Nabathæans, and in 310 Demetrius, his son, invaded them again. One of the Ptolemies annexed a narrow strip of Arabia to his dominions. In 219 Antiochus the Great captured the city of Rabbath Moab and subdued several tribes. After that the northern Arabs were frequently involved in wars with the new Jewish state, and fortified several cities on its border, as Bostra, Medabah, and Hesbon. Several Roman proconsuls of Syria undertook expeditions against them, but without any further advantage than the payment of a tribute or temporary cessation of hostilities.—In the reign of Augustus, Ælius Gallus, prefect of Egypt, undertook his famous expedition into Yemen at the head of 10,000 Roman legionaries, 500 Jews, and 1,000 Nabathæans; 80 ships of war and 130 transports conveyed these troops down the Red sea under the guidance of Syllias, by whose treachery numbers of the vessels were wrecked. Gallus penetrated as far as Mariaba, represented as the capital of the Rahminites, but effected nothing. Other useless expeditions followed. In A. D. 362 the army of the emperor Julian besieged and destroyed Anbar, the capital of the kings of Hoja.—A new era dawned on Arabia at the birth of Mohammed (about 570). His doctrines soon gained a firm foothold, and Mecca once conquered, he found nearly the whole peninsula at his feet. Abu-Bekr, Omar, Othman, and Ali, who succeeded Mohammed in turn under the title of caliph or emir-el-mumenin, "commander of the faithful," carried forward what he had begun. In the reign of Ali, Moawiyah, governor of Syria, cast off his allegiance, was proclaimed caliph by the western provinces, penetrated into Hedjaz, reduced Medina and Mecca, and extended his conquests as far as Yemen. A few months after Ali's death the sovereignty passed into the hands of Moawiyah, the first prince of the dynasty of the Ommyyades, who held the supreme power over the Moslem empire till A. D. 750. This period is marked

by internal dissensions and bloody struggles, Walid I., one of this line, abolished the use of the Greek language and characters, which had hitherto been employed in keeping the accounts, and ordered his clerks and secretaries to substitute the Arabic, a change to which very probably we owe the invention or at least the familiar use of our present numerical figures. To this dynasty, which ruled for nearly 90 years, succeeded that of the Abbassides, who transferred the seat of the caliphate from Cufah to Bagdad, and held sway over a large part of the Mohammedan countries from the 8th to the 13th century. The subsequent history of Arabia is but a succession of quarrels among its numerous petty chiefs, except the reform movement of the Wahabees, a sect founded in the middle of the 18th century by Mohammed ibn Abd-el-Wahab. (See WAHABEES.) In 1870 and 1871 a rebellion broke out among the Bedouins in Hedjaz, which was with difficulty suppressed by the Turkish troops.—See "History of Arabia," by A. Crichton (Edinburgh, 1834), and "Journey through Central and Eastern Arabia," by W. G. Palgrave (London, 1871).

ARABIC LANGUAGE AND LITERATURE. The Arabic belongs to the southern branch of the Semitic family of languages, and after the Hebrew is the most important member of the family. The other members of the southern branch are the Himyaritic and the Ethiopic. The particular dialect which, mainly through the influence of the Koran, became the standard of the literary language, was that spoken in the central part of Arabia, in Hedjaz and Nedjed. Partly perhaps because of its sheltered position, but partly also because of an unusually strong conservative tendency, the Arabic, though the latest of the Semitic languages to acquire historical importance, is in its forms the most archaic of all. Nowhere else are the inflections so fully preserved, and for the comparative study of these languages the Arabic is of the first importance. In wealth both of grammatical forms and of vocabulary it is equalled by few languages, and no other of the Semitic family approaches it. The characteristic features of the family, the prevailing triliteral and consonantal character of the roots, and the modification of the radical meaning by a significant change of vowels within the root, appear most clearly in the Arabic. There are other features which, if not altogether peculiar to it, are found in the other dialects only in a rudimentary or fragmentary state. Such are the system of case endings and the so-called "broken plurals," that is, collective nouns which have nearly supplanted the proper plurals formed by means of terminations. The number of derived forms of the verb, commonly called conjugations, is also considerably larger in Arabic, each verb having, at least theoretically, 15; and the mode forms are likewise more numerous. As an instrument of thought the Arabic is characterized

by great flexibility, delicacy, and precision. While the other Semitic languages have only a very simple syntactical structure, unsuited to the expression of any but the more obvious relations of thought, the Arabic has an extensive philosophical literature. The external history of the Arabic is remarkable, furnishing in many respects a parallel to that of the Latin. It has taken possession of nearly the whole field formerly occupied by the Semitic family. It has also spread over the whole north of Africa, and in central Africa it is still aggressive. The present Arabic-speaking races number about 35,000,000. Where it has not supplanted, it has strongly impregnated the languages with which it has come in contact. The Turkish and Persian have borrowed from it nearly one half of their vocabularies, the Hindostani but little less, the Hindi and Malay quite largely. The languages of western Europe have felt its influence, the Spanish, as was natural, most strongly. Elsewhere it is to be traced mainly in the presence of various scientific and technical terms, such as *algebra*, *alchemy*, *azimuth*, *nadir*, *cipher*, *alcohol*, *elixir*, *magazine*. A glossary of words of Arabic derivation found in Spanish and Portuguese has been published by Dozy and Engelmann (2d ed., Leyden, 1869); in French, by Pihan (Paris, 1851); in Dutch, by Dozy (Leyden, 1867). The literary Arabic has during its whole history remained almost without change, and the various dialects now spoken, when we consider the long period (12 centuries) and the wide territory which they cover, show remarkably little divergence either from the literary language or from each other. They differ from the written language mainly in the frequent loss of final vowels, and with them of inflections of the noun and verb, which they served to distinguish. Phonetic decay has reached about the same stage of progress in the Arabic now spoken that we find in the Biblical Hebrew.—The Arabic alphabet is derived from the Estrangelo, or Old Syriac, and more remotely from the Phœnician, and was introduced not more than a century before Mohammed. It no doubt consisted originally, like the Estrangelo, of 22 characters, which number was afterward raised by the use of diacritical marks to 28. Like all the Semitic alphabets, it is written from right to left, and is essentially consonantal. The vowel signs, written above and below the line, are a later invention, generally attributed to Abul-Aswad, the earliest Arab grammarian, who died in 688. These vowel and diacritical signs were first applied to the Koran, in order to put an end to the disputes to which the previous ambiguous mode of writing had given rise. The Arabic system of vowel notation, unlike the Hebrew and Syriac, is strictly etymological. Only the fundamental vowels *a*, *i*, *u*, long and short, and the diphthongs *au*, *ai*, are written, although in speaking several intermediate vowels are heard. Both in manuscripts and in printed texts

the vowel signs are frequently omitted either wholly or in part. There are several forms of the Arabic character, of which the Cufic, so called from the city of Cufah, the seat of one of the early grammatical schools, was the first to gain general currency, though from an early date the *neskhi* or copy-hand was in use, and since the 10th century has been the prevailing form. Of the remaining forms, some, as the Maghrebine or Moorish, have a local currency, and others are employed for special uses. The Arabic alphabet has gained a wide vogue beyond the limits of the language, having been adopted by the Persian, Afghan, Hindostani, Turkish, Malay, and in quite recent times by the Berber and other African dialects. The original defects of the alphabet are seriously aggravated when it is applied to languages of different families.—Grammar was the first of the sciences cultivated by the Arabs, the special motive being the necessity for fixing the text of the Koran; and though it soon reached the limit of its development among them, it always remained a favorite study. The earliest grammatical work which has been preserved is that of Sibawaih, about 780; one of the most celebrated, the subject of numerous commentaries, is the *Alfya* (so called because composed of 1,000 verses) of Ibn Malek, who died in 1273 (Arabic by Dieterici, Leipsic, 1851; Arabic and French by De Sacy, Paris, 1833). Of those by European scholars, the best are by De Sacy (2d ed., Paris, 1831) and Ewald (Leipsic, 1831–3). Among grammars devoted to the spoken idioms may be mentioned those of Caussin de Perceval (Paris, 1835), Marcel (on the African dialects generally, 2d ed., Paris, 1869), and Pihan (dialect of Algiers, Paris, 1851). Of the native dictionaries, the chief are the *Sihah* of Al-Jauhari (died about 1007); the *Lisan el-Arab* of Ibn Mukarran (died 1311); the *Kámús* of Firuzabadi (died 1414), containing 60,000 words (printed at Calcutta, 1817, and at Cairo, 1864); and the *Taj el-Arús*, an enormous compilation, of which the *Kámús* forms only about a seventh part, made at Cairo in the last century. The materials of the large Arabic-English lexicon of Lane, now in progress (Parts i. to iii., London, 1863–7), are drawn mainly from the last-mentioned work. Among the other European lexicographers, the chief are Golius (Leyden, 1653) and Freytag (Halle, 1830–37).—The Arabs have produced a literature of vast extent, and after large reductions from the extravagant estimate sometimes put upon it, a very high value must still be allowed it. It commences with poetry. The oldest remains, in which however the characteristic form and style of Arabic poetry appear already fully developed, go back about a century before Mohammed. With the Koran a new era begins in literary as well as in political history. The Koran was to the orthodox believer not only the rule of faith, but also the highest authority in law, the perfect model in point of style—not simply inspired, but uncreated and eternal. Un-

der the Ommiyade dynasty of Damascus, what there was of literary activity was concentrated mainly on the Koran, the establishing of the text and interpretation, and on the preservation of the traditions of the prophet. The following century, under the Abbasside caliphs of Bagdad, Al-Mansour, Haroun al-Rashid, Al-Mamoun, and Motassem, was the most flourishing period of Arabic literature. Greek philosophy and science were introduced, mainly through the agency of Syrian Christians, and through the medium of translations, made for the most part not directly from the Greek, but from the Syriac. Law, history, and geography were cultivated, schools and libraries established, rewards bestowed on poets and scholars. In this patronage of literature the princes of the Ommiyade dynasty in Spain, especially Haken II. (961–976), were worthy rivals. After the capture of Bagdad by the Mongols in 1258 the literary spirit gradually declined, and for the last three centuries little has been produced but commentaries on the older literature, and some works of an encyclopædic character. The field in which the Arabs have shown most originality is unquestionably poetry, and its golden age was the century before Mohammed. Of the poems of this period, the most celebrated are the seven *Moallakát*, so called, according to the common but doubtful tradition, because they were “suspended” in the Caaba at Mecca, an honor bestowed on such as carried off the prize in the poetical contests. They have been frequently published, both together (Arabic by Arnold, Leipsic, 1850; English by Sir William Jones) and separately. One of the seven, Amrukkais (German by Rückert, Stuttgart, 1843), holds a first place among all the Arabic poets. Three others deserve to rank with these, Nabiga, Alkana, and Al-Asha; the first two published by Ahlwardt in “*Divans of Six Ancient Arabic Poets*” (London, 1870). Specimens of many other early poets are found in the *Hamása* of Abu Temam (Arabic and Latin by Freytag, Bonn, 1828–47; German by Rückert, Stuttgart, 1846); in the *Hamása* of Bolhori, and in the *Kitáb el-Agháni* of Ali of Ispahan (Arabic and Latin by Kosegarten, vol. i., Greifswald, 1840). Motanebbi, about the middle of the 10th century (Arabic by Dieterici, Berlin, 1861; German by Von Hammer, Vienna, 1824), is the greatest of the poets after the advent of Mohammed. Arabic poetry is almost exclusively lyrical. Epic and dramatic poetry they have not, and the rhymed treatises on grammar and other prosaic subjects can hardly be classed with didactic poetry. In proverbs Arabic literature is rich, and several collections made by native authors, chief among which is that of Meidani, have been published by Freytag (Arabic and Latin, Bonn, 1838–43), and a smaller collection by Burekhardt (Arabic and English, London, 1830). The *Makamat* of Hariri (Arabic by De Sacy, 2d ed., Paris, 1847–53; English by Preston, London, 1850) is a collection of amusing adventures, narrated

with much grace and skill in most artfully rhymed prose, interwoven with short poems. It has been admirably imitated, rather than translated, in German by Rückert (Stuttgart, 1837). The romance entitled "Adventures of Antar," of which about a third part has been translated by Hamilton (4 vols. 8vo, London, 1820), is a charmingly drawn picture of Arab life before the rise of Mohammedanism. The famous collection of tales known as the "Thousand and One Nights," or the "Arabian Nights," is of unknown date and authorship. It was first made known in Europe about the end of the 17th century by Antoine Galland, who was employed by Colbert to collect MSS. in the East. The copy of the Arabic MS. brought by Galland from Syria contained a marginal note dated 1584, and from internal evidence the middle of the 15th century has been fixed upon as the probable period of the composition of the work. Some of the tales were evidently borrowed by the writer from older authors, and Von Hammer identifies at least the plot and some of the stories of the "Arabian Nights" with an earlier collection in Persian, called *Hezar Afsaneh* (Arab. *Elf Khurafeh*, "The Thousand Fanciful Stories"). An excellent translation, with elaborate critical and illustrative notes, was made in England by Lane.—Theology and law among the Arabs, as in the East generally, were very closely connected, both resting on the common foundation of the Koran. But the Koran being contradictory on some points, silent on many others, and altogether without order or system, recourse was had first to the oral traditions of the sayings and doings of Mohammed; next to the decisions of the imams or legitimate successors of the prophet, and the early caliphs; and where these failed, to analogical reasoning. Of the commentaries on the Koran, the most esteemed is that of Beidhawi (published by Fleischer, Leipsic, 1844-'8); and of the collections of traditions, that of Bokhari (Krehl, Leyden, 1862-'8). Sharastani gives a view of the many religious and philosophical sects into which Islam was divided (Arabic by Cureton, London, 1842-'6; German by Haarbrücker, Halle, 1850-'51). The great schism is that which divides the Sunnis, the orthodox party, who recognize the authority of the traditions and decisions above mentioned, from the Shiah, the followers of Ali, who reject many of them. The latter sect prevails chiefly in Persia. There are four leading schools among the Sunnis, all regarded as orthodox, and called after their founders the Hanefite, Malekite, Shafiite, and Hanbalite. They agree in their general principles, but differ in various details, and all date from near the commencement of the Abbaside dynasty. The Hanefite code prevails in India and Turkey; the Malekite in Africa, except Egypt. In Egypt the generally received authority is the Shafiite code, but the courts are Hanefite, the cad being sent from Constantinople. The fourth or Hanbalite school has little influence. The most cele-

brated digest of the Hanefite code is the *Hidayat*, translated into English by Hamilton (Calcutta, 1791); another, the *Multaka al-Abkar*, translated into French, is contained in D'Oshson's *Empire Ottoman* (Paris, 1787-1820). The collections of decisions are also weighty authorities. One of them, the *Futawa Akenjir*, made by order of the emperor Aurungzebe, was printed in Calcutta (6 vols. 4to, 1828-'35), and a portion of it relating to the law of sale has been translated into English by Baillic (London, 1850). The chief authority on the law of inheritance, the *Sirajiyat*, was translated by Sir William Jones (Calcutta, 1792). A compendium of the Malekite code by Khalil ibn Ishak has been translated into French by Perron (Paris, 1848-'52); another of the Shafiite code, by Abu Shofa, has been published by Keijzer (Arabic and French, Leyden, 1859).—Of historical works the number is very large (Hadji Khalfa enumerates 1,300), and the materials for the history of the countries and periods embraced in the Mohammedan dominion are very full and valuable, but outside of this meagre. In style they are for the most part mere chronicles, seldom rising to a comprehensive survey or attempting to trace the deeper historical connections of events. It is a common habit of the writers to quote largely from their authorities, and this makes amends in part for the absence of anything like historical criticism. The following are some of the more important works that have been published, beginning with general histories: *Abulfeda, Historia Muslemica* (Arabic and Latin by Reiske, 6 vols. 4to, Copenhagen, 1789-'94), and *Historia Antemuslemica* (Arabic and Latin by Fleischer, Leipsic, 1831); Masudi, "Historical Encyclopædia" (Arabic and French by Barbier de Meynard, vols. i.-vi., Paris, 1861-'71; English by Sprenger, London, 1841, vol. i. only); Tabari, "Annals" (Arabic and Latin by Kosegarten, Greifswald, 1831-'53); Ibn al-Athiri, "Chronicle" (Tornberg, Upsala and Lund, 1851 *et seq.*); Ibn Koteiba, "Manual of History" (Wüstenfeld, Göttingen, 1850); Ibn Ettiktaka (Alhwardt, Gotha, 1860); and Hamza of Ispahan (in Arabic and Latin by Rasmussen, Copenhagen, 1817). Histories of the early conquests: Al-Beladzori (De Goeje, Leyden, 1863-'7), and Al-Wakidi, "Mohammed's Campaigns" (Calcutta, 1856), "Conquest of Syria" (Lees, Calcutta, 1854), "Conquest of Mesopotamia" (Arabic by Mordtmann, German by Niebuhr, Hamburg, 1847). Histories of particular countries: Al-Makkari, on the history and literature of the Spanish Arabs (Arabic by Dozy and others, Leyden, 1855-'61; English, with omission of the parts relating to literary history, by De Gayanous, London, 1841-'3); Ibn Adhari, Africa and Spain (Dozy, Leyden, 1848-'51); Ibn Abi Zer, *Annales Regum Maurætanie* (Arabic and Latin by Tornberg, Upsala, 1843-'6; French by Beaumier, Paris, 1860); Makrizi, "History of the Mameluke Sultans" (French by Quatremère,

Paris, 1835-'7), "History of the Copts" (Arabic and German by Wüstenfeld, Göttingen, 1845); Ibn Taghri, annals principally of Egypt (Juynboll and Matthes, Leyden, 1852-'61); a collection of chronicles by various writers relating to the city of Mecca (Wüstenfeld, Leipsic, 1857-'9); a collection relating to Sicily (Amari, *Bibliotheca Arabo-Sicula*, Leipsic, 1855-'7); Al-Suyuti, "History of the Temple at Jerusalem" (English by Reynolds, London, 1836). To the general character of Arabic historical writing above given, we have a noble exception in Ibn Khaldun (died 1406), a writer of a philosophical spirit and a profound historical sense. Of his history, the introduction has been published by Quatremère and translated into French by De Slane (in the *Notices et extraits des manuscrits*, vol. xvi. *et seq.*), and another part, the history of the Berbers, edited and translated by De Slane (Algiers, 1847-'56). Among biographies, that of Mohammed by Ibn Ishak (Arabic by Wüstenfeld, Göttingen, 1858-'60; German by Weil, Stuttgart, 1864) is especially important. —For original speculation in philosophy we must look rather to the religious sects than to the philosophers so called, a name reserved for those who borrowed the systems of the Greeks, especially that of Aristotle, in which they introduced few changes of importance. The most celebrated names among the eastern Arabs are Alkindi of the 9th, Alfarabius of the 10th, and above all Ibn Sina (Avicenna) of the early part of the 11th century. More profound and original was Algazzali (died 1111), who aimed at the overthrow of the existing systems, and from skepticism passed finally to asceticism and mysticism. With respect to the idea of cause, he held substantially the position and anticipated the arguments of Hume. In the 12th century Spain became the centre of philosophical activity, its chief representatives being Ibn Badja (Avempace), Ibn Tophail (Abubacer), and Ibn Roshd (Averroes). The schoolmen first obtained the Latin translations of some of the treatises of Aristotle, not directly from the Greek, but from Arabic versions, and Averroes, as the latest of his commentators, was accepted as his authorized interpreter. In the 13th and 14th centuries the authority of his commentary was hardly questioned, and in the 15th and 16th it was many times reprinted. These circumstances give to Arab philosophy a far higher importance in the history of European culture than its independent value would entitle it to claim.—In mathematics the Arabs were the pupils of Greece and India, but they added not a little to the sunn of knowledge which they had received. Neither algebra nor the Arabic numerals were, as the names would seem to indicate, of Arab invention; but the Arabs perfected the processes of the one, arriving at the solution of cubic equations, and they facilitated the introduction of the other. They simplified trigonometrical calculations by substituting the use of sines and tangents for chords.

In astronomy they improved the instruments of observation (Abulhasan, "Treatise on Astronomical Instruments," French by Sédillot, Paris, 1834-'5), and constructed new and more accurate tables (Ibn Yunis, Arabic and French by Caussin, Paris, 1804; Olug-Beg, Arabic and French by Sédillot, Paris, 1847-'53). They made some discoveries of importance, among which is perhaps to be reckoned that of the variation of the moon by Abul-Wefa, commonly ascribed to Tycho Brahe, six centuries later.—The science of medicine owes much to the Arabs, especially in the departments of pharmacy and materia medica. In surgery, from ignorance of anatomy, they made little advance. The most celebrated among the medical as well as among the philosophical writers is Avicenna, whose "Canon of Medicine" was for four centuries the leading text book in European schools (printed at Rome, 1593, and in Latin versions not far from 30 times). The *Elkavi* or *Continens* of Al-Razi (Rhazes) enjoyed also a wide reputation, and in the Latin translation passed through many editions. The study of medicine led naturally to that of chemistry and botany. Chemistry made substantial progress among the Arabs. To Geber we owe the first preparation of sulphuric and nitric acids and aqua regia. The distillation of alcohol also, as the name implies, was a discovery of the Arabs. Botany was little more than the handmaid of medicine. There was no attempt at scientific classification, but only an alphabetic arrangement of the material, as among the Greek botanical writers. But in the number of plants described, the style of description, and the determination of synonymes, the advantage is largely on the side of the Arabs. The best known writers are Al-Nabati and Ibn Baitar (German by Sontheimer, Stuttgart, 1840-'42). —In geography the Arabs have rendered most important services, less in the mathematical than in the descriptive branch of the science. The vast extent of the empire of the caliphs, and the reports gathered from the governors of remote provinces, the commercial intercourse reaching even beyond the limits of the empire (witness the Arabic coins frequently dug up in northern Russia and even in Norway, which prove the existence of an established trade, if they do not necessarily suppose the presence of Arab merchants), the pilgrimage to Mecca, which it was the duty of every Moslem who had the ability to make once at least in the course of his life—all this could not but add materially to the sunn of geographical knowledge. The narrative of an Arab merchant named Soleyman, who visited China in the 9th century, was published in Arabic and French by Reinaud (*Relation des voyages dans l'Inde et à la Chine*, Paris, 1845). Al-Ishtakhrî and Ibn Haukal about 950 traversed the different Mohammedan provinces from the Atlantic to India. The *Liber Climatium* of the former was published by Möller (Gotha, 1839; German by Mordtmann, Hamburg, 1845).

The "Oriental Geography of Ibn Haukal," by Ouseley (London, 1800), is translated from a Persian version in which the works of Al-Istakhri and Ibn Haukal have been recast and combined in one. Especially important are the geography of Edrisi (about 1150), who lived at the court of Roger II. of Sicily, and who visited England (French by Jaubert, Paris, 1836-40; and the portion relating to Africa and Spain, Arabic and French, by Dozy and De Goeje, Leyden, 1866); the "Geographical Dictionary" of Yakut (died 1229), published by Wüstenfeld (Leipsic, 1866 *et seq.*); geography of Abulfeda (Arabic by Reinaud and De Slane, Paris, 1840; French by Reinaud, Paris, 1848). Ibn Batuta (died about 1377) surpassed all in the extent of his travels, which reached from Spain to China and into central Africa (Arabic and French by Deffrémery and Sanguinetti, Paris, 1853-9; English, abridged, by Lee, London, 1829). Abdallatif, a physician, wrote an account of Egypt, founded on his own observations, and of great value (De Saey, Paris, 1810). He took advantage of a plague in Cairo in 1201-2, of which he gives a graphic description, to make anatomical investigations. The Arab geographers, instead of following in their descriptions political or physical divisions of the globe, generally adopted, after the example of the Greeks, the system of climates or zones, usually seven. In the determination of latitudes and longitudes, of the magnitude of the earth, and the shape of the continents, they made a somewhat nearer approach to the truth than the Greek geographers. Under the caliph Al-Mamoun (813-33), a measurement was made of the length of a degree of latitude.—Such is the extent of Arabic literature that, notwithstanding the labors of European scholars and the production of native presses, especially at Boulak, Cairo, and in India, and recently in England, where Rîkâ Allah Hassoun, an Arabic poet, has devoted himself to the production of standard works, the greater part even of what has been preserved is in manuscript, and still more has perished. In proof of the great number of works lost, we need not appeal to the exaggerated accounts of the libraries of some of the Mohammedan princes (Ihakem II. of Spain is said to have collected 600,000 volumes). Works in literary history, always a favorite department with the Arabs, furnish abundant evidence. The most important of these works are the *Fihrist* or "Catalogue of Sciences" of Ibn al-Nadim, of the 9th century (published by Flügel, vol. i., Leipsic, 1871); the "Biographical Dictionary" of Ibn Khallikan, of the 13th century (Arabic by Wüstenfeld, Göttingen, 1835-50; French by De Slane, Paris, 1842-71); and Hadji Khalifa's (died 1635) "Dictionary of Arabic, Persian, and Turkish Literature" (Arabic and Latin by Flügel, 7 vols. 4to, Leipsic, 1835-58). Hammer-Purgstall's "Literary History of the Arabs" (7 vols. 4to, Vienna, 1850-56), which comes down only to the year 1258, contains notices of about 10,000 writers.

Of the printed books a tolerably complete index is contained in Zenker's *Bibliotheca Orientalis* (Leipsic, 1846-60).

ARABICI, or **Arabians**, a Christian sect of the 3d century, founded by Beryllus, bishop of Bostra in Arabia. They denied the divinity of Christ, and affirmed that the soul dies with the body, and is raised to life again with it in the resurrection. Origen contended with Beryllus, and a synod condemned the Arabici.

ARACAN, or **Arracan**. **I.** A division of British Burmah, including the districts of Akyab, Sandoway, and Ramree, bounded W. by the bay of Bengal, S. by Pegu, and separated by the Youmadoung mountains on the E. from Ava; area, 23,529 sq. m.; pop. in 1871, 447,957. It is a hilly region, with numerous fertile plains and valleys, dense jungles, and pestiferous marshes. The coast has very few harbors, and though the country is rich in timber, coal, petroleum, salt, tobacco, and rice, and has considerable trade, there are few important towns. The climate is very unhealthy to Europeans. The principal river is the Aracan or Kuladyne, which enters the bay of Bengal 15 m. N. of Akyab, after a S. course of about 200 m. The aboriginal inhabitants, called Mughls, constitute about half the population. Education is very general, few being unable to read and write. The province was conquered by the Burmese in 1783, and taken from them by the British in 1824. Capital, Akyab. **II.** A town, the former capital of the above province, on the river Aracan, about 50 m. from its mouth; pop. about 10,000. It is a straggling, decaying place, which once had about 95,000 inhabitants. The climate is extremely unwholesome.

ARACATI. **I.** A port of Brazil, in the province of Ceara, on the Rio Jaguaribe, about 10 m. from the sea, lat. 4° 31' S., lon. 37° 48' W.; pop. about 20,000. It has five churches, and a very fine town hall. Its exports are mainly cotton and hides. At the mouth of the river is a dangerous bar. Severe floods occur during the rainy seasons. **II.** A river in the same province, flows due N. about 120 m., and enters the Atlantic by two mouths, near Pernambuco, 150 m. N. W. of the town of Aracati.

ARACHNE, in Greek mythology, a Lydian maiden, famous for her skill in weaving. She challenged Minerva, and wove a piece of cloth on which the amours of the gods were represented. This work was so faultless that Minerva, despairing of being able to excel it, tore it to shreds, whereupon Arachne hung herself. The goddess loosened the rope and saved the life of Arachne; but the rope was transformed into a cobweb, and the maiden into a spider (Gr. ἀράχνη), that insect which Minerva most hated.

ARACHNIDA, a class of invertebrate animals belonging to the articulata, and including spiders, mites, and scorpions. The arachnida differ from insects in having no antennæ; in the number of eyes being in most species 8, and, even when only 2, in never being placed later-

ally on the head; in the legs being usually 8, although in some species 6, and in others 10; and in their respiratory apparatus consisting of radiated tracheæ. Most arachnida are carnivorous. Some parasitic species, such as the minute parasite mites, are furnished with a sucker, in some respects constructed like that of the gadfly. In other species there is a pair of upper jaws and a pair of under jaws carrying jointed feelers, and between them a sort of tongue formed by a projection from the breast. At the back of the mouth there is a piece of horny texture, termed by Savigny, Latreille, and Audouin the pharynx, forming the entrance into the gullet. The gullet, the stomach, and the intestines run in a direct line from the pharynx to the vent. In most arachnida there is a complete circulatory system of arteries and receiving veins, returning blood. The respiratory organs have two peculiarities, on which Latreille established his two great divisions of arachnida, *pulmonaria* and *trachearia*. The *pulmonaria*, which Straus-Dürckheim and Léon Dufour place in the first or chief division, comprises the numerous species of spiders and the scorpions. Their respiratory apparatus consists of small cavities formed by the union of triangular laminae of extreme thinness. The division furnished with air pipes (*trachearia*) similar to those of insects, comprises the harvest or shepherd spiders, mites, and other genera. "The presence of tracheæ, or air pipes," says Latreille, "excludes all complete circulation; that is, the distribution of blood to different parts, and its return from the respiratory organs to the heart." The eyes of the arachnida are all simple. In most species of spiders they are 8 in number, but in some they are 6 and in others only 2. Nothing is known of the organs of hearing in arachnida, although it has been well ascertained that these animals do hear. Male spiders are always much smaller than the females. The *palpi* or feelers of the male are furnished with organs of various forms, usually bulging at the tip; the feelers of the female gradually taper to a point. The eggs of spiders, not having a hard shell, are soft and compressible. Before being laid, they lie in the egg bag, squeezed together and flattened, within the spider's body, but assume the globular form after being laid. The female spider, in preparing a nest for her eggs, uses her own body as a bird uses its body to give form and proper size to its nest. The eggs are excluded from a cavity just behind the breast. The hatching of the eggs of one species (the *epicra diadema*) has been traced with care, and the successive evolution of the embryo depicted with skill, by Moritz Herold of Marburg.—Latreille arranges the arachnida into two great orders, *pulmonaria* and *trachearia*. He subdivides the first order, *A. pulmonaria*, into two families, under the names of *araneida* and *pedipalpi*. The *araneida* include our common spiders, having palpi simple, pediform; mandibles armed with a movable and

perforated claw, emitting a poisonous liquid; abdomen inarticulate, terminating by spinnerets. The *pedipalpi*, including the scorpions and their allies, have the abdomen articulate, without spinnerets; palpi produced, cheliform (*chela*, claw), or shaped like pincers; mandibles with a movable digit. The second order, *trachearia*, includes various forms of shepherd spiders and sea spiders, mites, and ticks; true mites, garden mites, spider mites, wood mites; true ticks, plant ticks, water ticks, harvest ticks; false scorpions, book scorpions; shepherd spiders, sea spiders, and parasitic sea spiders.

ARAD, a town of Hungary, capital of the county of the same name, on the right bank of the Maros, 19 m. N. of Temesvár; pop. in 1869, 32,725. It is the seat of a Greek bishop, and contains a gymnasium and Wallachian college. Considerable trade is carried on with Germany and the Black sea, chiefly in tobacco and cattle. Its annual fair is second only in importance to those of Pesth and Debreczin. In the 17th century the city was captured and destroyed by the Turks. It is skirted on two sides by the Maros, and defended by a fortress, which, held by the Austrians, capitulated only after a long siege to the Hungarian army in the revolutionary war of 1849. Three months later (Oct. 6), Arad witnessed the execution by the Austrian authorities of 13 Hungarian generals and colonels, who had surrendered with Görgey at Világos (Aug. 13), or, following his example, a few days later.—On the opposite bank, and connected by a bridge, is New Arad (Hung. *Uj Arad*), in the county of Temes; pop. 4,960.

ARADUS (now *Raud*), a rocky islet, about a mile in circumference, lying 2 m. off the Syrian coast, in lat. 35° N., 35 m. N. of Tripoli. It was early occupied as a stronghold by the Phœnicians, known to the Hebrews as Arvad, a city second only to Tyre and Sidon, and held supremacy over a considerable tract on the adjacent mainland, where Antaradus was founded. The city shared in the general fortunes of Phœnicia, and about A. D. 638 was destroyed by Moawiyah, the lieutenant of the caliph Omar, and never rebuilt. Aradus is the only island on the Syrian coast mentioned by the historians of the crusades. It is now occupied by about 3,000 people, mainly fishermen. Remains of the old Phœnician walls are still to be seen.

ARAFAT, or **Orphat** (Arabic, gratitude), a granitic hill in Arabia, near Mecca, a pilgrimage to which is enjoined upon all who visit that city. It rises about 200 feet above the plain. The pilgrimage occupies three days from Mecca. On the second day the ceremony of the sermon on the mount is observed. The *cadi* of Mecca usually preaches the sermon, riding first upon a camel up the entire length of the stone steps which ascend the mountain to the summit. Hearing this sermon is the great point of the pilgrimage, and confers the title of *hadji* (pilgrim). There is a tradition among the Mohammedans that on this moun-

tain Adam first met Eve again, after a separation of 120 years immediately following the expulsion from paradise. On the summit is a chapel, which, according to tradition, was built by Adam himself.

ARAGO. I. Dominique François, a French physicist and statesman, born at Estagel, near Perpignan, Feb. 26, 1786, died in Paris, Oct. 2, 1853. After studying mathematics at the college of Perpignan, he entered in 1803 the polytechnic school. On leaving it in 1805, he was appointed secretary of the board of longitude, and in 1806 he was commissioned to finish in conjunction with Biot the measurement of an arc of the meridian in Spain, begun by Delambre and Méchain, as the basis of the decimal metrical system of France. He was employed in the island of Majorca on the outbreak of war, taken for a spy, saved from the mob by some months' confinement in a fortress, afterward taken by Spanish corsairs from an Algerine vessel and harshly treated, enlarged on the demand of the dey, shipwrecked on the coast of Sardinia, and after new perils reached Algiers in a Bedouin disguise. Here he was treated with suspicion by a new dey, but finally reached Marseilles in a French frigate in 1809. On his arrival in Paris he was elected a member of the institute, though only 23 years old, and soon afterward appointed professor at the polytechnic school. In 1830 he became perpetual secretary of the academy of sciences, and director of the observatory, a post which he retained till his death. He rendered special services to optics by his own experiments, and by his influence over others, and especially by directing the labors of Fresnel and Malus. He was the first to recognize the value of Young's optical papers. He investigated magnetical phenomena, and made some contributions to meteorology, especially in connection with electricity. He also successfully investigated the colors of polarized light, the application of polarization as a test of the origin of light, the experimental proof of the retardation of light in dense mediums, the apparent magnetism of copper rotating near a permanent magnet, and the influence of the aurora upon the needle. For the last three years of his life he was blind and otherwise a sufferer. He was the author of more than 60 distinct memoirs on various branches of science. He established, in concert with M. Gay-Lussac, in 1816, the *Annales de chimie et de physique*. The article in the "Edinburgh Encyclopedia" on the polarization of light is from the pen of Arago. His complete works appeared in Paris in 17 vols. (1855-'60), under the direction of Barral. From the royal society of London he received in 1829 the Copley medal, an honor never before conferred upon a French man of science. When Napoleon, after the battle of Waterloo, thought of emigrating to the United States, for the purpose of devoting the remainder of his life to scientific pursuits, he invited Arago to accompany him; and when this intention was

foiled by the English, Monge endeavored in vain to prevail upon Arago to follow the ex-emperor to St. Helena. On the outbreak of the revolution of 1830, Arago espoused the cause of the people. In 1831 he was elected member of the chamber of deputies by his native department of Pyrénées-Orientales, and took his seat on the extreme left. He delivered memorable speeches in behalf of science and education, and in the political questions of the day he strenuously opposed all encroachments upon the rights of the people, and denounced the government monopoly of railways and the project of the fortifications of Paris. He was also a member of the council general of the Seine, of which he was president till 1849, and the declaration of the council in favor of the emancipation of slaves was due to him. He took a conspicuous part in the movement which led to the overthrow of Louis Philippe, and on Feb. 24, 1848, he became a member of the provisional government, and officiated first as minister of marine, and afterward added to the functions of this office the duties of the war department. He belonged to the republican wing of Marrast and Marie, who opposed the theories of the socialists, and advocated liberal institutions, as they exist in the United States. At the same time he represented his native department in the constituent assembly. When the provisional government surrendered the reins of power, the assembly appointed him member of the executive commission. In this position he displayed great personal courage during the bloody days of June, 1848. He opposed the election of Louis Napoleon to the presidency, and gradually ceased to take part in public affairs. But to the last he proved true to his republican creed, and after the *coup d'état* of December, 1851, refused to take the oath to the government of Louis Napoleon.

II. Jean, brother of the preceding, born in 1788, died in Mexico, July 9, 1836. He was a sub-treasurer in Perpignan, and, having been deprived of his appointment on a denunciation which subsequently turned out to be false, he embarked for New Orleans, and, joining the younger Mina, became a general in the Mexican service in the war of independence.

III. Jacques Étienne Victor, brother of the preceding, born at Estagel, March 10, 1790, died in Brazil in January, 1855. When only 20 years of age he made an artist's tour through various countries of the Mediterranean. In 1817 he sailed in the exploring vessel Uranie as draughtsman to the expedition. The ship was wrecked at the Moluccas, and Arago did not return to France till 1821. He afterward resided at Bordeaux and Toulouse, and lost his sight in 1837, which, however, did not prevent him from engaging in new voyages. His most interesting work is *Souvenirs d'un aveugle: Voyage autour du monde* (with illustrations and comments by François Arago, 2 vols., Paris, 1838 *et seq.*).

IV. Étienne, brother of the preceding, born at Perpignan, Feb. 7,

1803. He studied at Lorèze, and undertook a course of chemistry at the polytechnic school, which he quitted for the purpose of joining the secret societies. He established the *Lorgnette* and *Figaro* newspapers, and was director of the Vaudeville until it was burned down. He has written upward of 100 theatrical pieces, including *Les aristocrates*, a five-act comedy, produced at the Théâtre-Français. In 1830 he closed his theatre to join in the popular movement, and distributed the theatrical stock of arms to the people during the three days of July. He was among the most prominent to signalize his disapproval of the shortcomings of Louis Philippe's government, which cancelled his theatrical license in 1840. The *Réforme*, a daily democratic journal, was founded by Étienne Arago. He was one of the prime movers in the revolution of 1848, and placed himself in the direction of the post office, which post he held till the retirement of Gen. Cavaignac. In 1849 he was expelled from France for his participation in revolutionary movements, and went to Belgium, which country he was also obliged to leave in 1851 at the request of Louis Napoleon; and after wandering about in different countries, he settled at Turin. The amnesty of 1859 enabled him to return to Paris. He attracted much public attention in 1862 by leaving the *société des gens de lettres* upon the ground of its being controlled by the banker Mirès and other schemers. In 1870 he was mayor of Paris from Sept. 5 to Oct. 31, when the invasion of the hôtel de ville forced him to retire. Among his later productions are a poem on Spa, the Belgian watering place (Brussels, 1851); a historical novel relating to the Vendean wars, *Les Blancs et les Bleus* (2 vols., Paris, 1862); and a vindication of his course in the February revolution, *Les postes en 1848* (1867). **V. Emmanuel**, an advocate and politician, son of Dominique François, born in Paris, Aug. 6, 1812. His name as well as his opinions and tendencies caused him to be retained in several political cases of importance. In 1839 he defended Barbès and Martin Bernard. He took an active part in the revolution of 1848. When the abdication of Louis Philippe was announced in the chamber, Arago, who had penetrated thither, rose and loudly proclaimed that royalty was by this act extinct, and that the people objected to a regency. Lamartine and other deputies followed, and a provisional government was organized on the spot. Lyons being in a turbulent state on account of destitution among the working class, Arago went there as commissary general, with plenary powers, and ordered 500,000 francs to be immediately applied in relief of the distress. This action was subsequently made the subject of furious party invective. He became a member of the legislative assembly for the Pyrénées-Orientales, and was envoy in Berlin from May till December, when on Louis Napoleon's election to the presidency he resigned, and strenuously opposed

him after his return to Paris in the constituent and subsequently in the legislative assembly. After the establishment of the second empire, he devoted himself almost exclusively to the law, acquiring distinction by defending in 1867 the Pole Berzowski, who attempted to murder the czar at the time of the Paris exposition, and in 1868, together with Gambetta and Crémieux, the journalist Peyrat, who had started the project of a monument in honor of Baudin. In 1869 he was put forward for the legislative assembly in two departments, but defeated by the government candidates. In 1870 he became a member of the provisional government without portfolio, resisting the aggressions of the rioters on Oct. 31. At the age of 20 Emmanuel Arago published a volume of poems, and was for five years afterward engaged in theatrical writing.

ARAGON, formerly a kingdom, now a royal captaincy general in the northeast of Spain, bounded N. by the Pyrenees, separating it from France, E. by Catalonia, S. E. by Valencia, S. W. by New Castile, and W. by Old Castile and Navarre; area, 17,984 sq. m., pop. in 1867 (estimated), 925,773. The surface is irregular from the numerous spurs of the Pyrenees that cross it, besides which it is separated from the neighboring provinces by ranges of lofty hills, that convert it almost into a basin. The Pyrenean chain in Aragon reaches a great altitude, some peaks exceeding 11,000 feet. The province is watered by the Ebro and its tributaries, the Huecha, Jalon, Jiloca, Huerva, Aguas, Martin, Guadalupe, and Nonaspe, on the right, the Gallego, Isuela, and Cinca on the left. A canal commenced in 1528 by Charles V. stopped short of its object, which was to reach the sea at Tortosa, and furnish a maritime outlet for the province. It extends from Tudela, in Navarre, to Sastago. Its average width is 69 feet, its depth 9 feet. It is mostly lined by high, thick walls, and crosses the Jalon river by an aqueduct 4,800 feet in length. The chief productions of Aragon are grain, flax, and hemp of good quality, fruits of various kind, maize, wine, and various dyestuffs. The mineral productions are iron, quicksilver, lead, copper, cobalt, marble, and coal. The mines and quarries are indifferently worked, the chief being one of rock salt near Remolinos. Cattle are not very plentiful, but sheep and swine are bred in considerable numbers. The mountains and forests abound in game. Aragon is divided into three provinces, Huesca, Saragossa, and Teruel. The principal city is Saragossa.—After the fall of the Roman empire Aragon passed into the hands of the Visigoths. Early in the 8th century it was conquered by the Moors, from whom it was eventually taken by the rulers of Navarre. In 1035 Ramiro I., son of Sancho III. of Navarre, received it in partition and raised it from a county to a kingdom. The four succeeding kings of the same house enlarged the kingdom, which, after the acquisition of the county of Barcelona, passed from the Navarre

to the Barcelona dynasty about the middle of the 12th century. The latter gave 11 kings to Aragon, ending with Martin in 1410, and won and kept the Balearic islands, Sicily, and Sardinia. The Barcelona dynasty was succeeded in 1412 by Ferdinand I. as the first king of the house of Castile. In consequence of the marriage of Ferdinand II. with Isabella, heiress of Castile, in 1469, Aragon and Castile were united, and the consolidation of the Spanish monarchy dates from the accession of their grandson Charles V. (1516).—The Aragonese had probably the earliest representative system of Europe. Their *fueros* (constitutional charter) compelled the king to take an oath to support them, to give to his subjects half the territory he should take from the enemy, not to enact laws without their consent, nor to declare war or to make peace without the consent of his counsellors. The *fueros* provided a cortes, in which all classes of the state were represented, and also enunciated principles of self-government and popular rights not exceeded by the liberalism of the present day. To insure the sovereign's adherence to this compact, a *justicia* was provided for as guardian of the laws. He was to be appointed by king and cortes together; his decisions were without appeal, and he was only answerable to the nation at large. The cortes were composed of the nobility, the caballeros, and the commons, to whom in 1301 the ecclesiastics were added. Unanimous consent of the king and the four orders was requisite to a law. The cortes were summoned and dismissed by the king, who presided at their deliberations in person, unless unable to do so, in which case the crown prince or his lieutenant was present. He could not remain in the cortes at the taking of the votes on a measure. Every Aragonese had the right to lay before the cortes any *grievances* (grudges or grievances) in relation to a breach of the *fueros* of the kingdom, and the cortes appointed a committee to report on the grievance. After all petitions and grievances had been disposed of, but not before, the cortes voted the supplies for the services of the state. These supplies were of a limited character. In 1376 the first money grant was asked by Pedro IV. to levy a body of men-at-arms. The Aragonese cortes refused, being "accustomed," as they said, "to serve the king with their persons, not their purses." Subsequently, the same king, however, coaxed his subjects into a loan. In 1412 Ferdinand I. obtained another loan, which loans paved the way to royal aids, benevolences, and other exactions. On the dissolution of the cortes, officers called a *disputacion*, and associated with the *justicia*, were appointed by the cortes to watch over the public interests until they met again. The Aragonese had an ancient constitutional right of taking up arms as a defence against the refusal of their king to observe and protect their *fueros*. The king at his coronation having taken the oath to uphold the constitution, protect the *fueros*, and do jus-

tice, the *justicia* who administered it replied in the name of the people, "We, who are worth as much as you, take you for our king and lord, provided you keep our laws and liberties; otherwise not." The decline of Aragonese liberty began with the union of the crowns of Aragon and Castile, which increased the power of the monarchy; and the accession of Charles V. was the death blow to the liberty and privileges of the Spanish cities and provinces. In the reign of Philip II. the *justicia*, Juan de Samoza, having summoned the people to arms to protect their *fueros*, the king sent a force against him, and wrote an autograph letter to his general, directing him to take and punish the *justicia* without delay; an order which was strictly obeyed, the judge being beheaded without form of trial.

ARAGONA, a town of Sicily, in the province and 8 m. N. by E. of Girgenti; pop. about 8,000. It is a very poor place, situated on a bare plain, backed by steep hills; but it has a large castle of the princes of Aragona, and is in the neighborhood of extensive sulphur mines, and of the mud volcanoes called Maccalube, which rise about 200 feet above the plain, and are known to have been in a state of continual activity for 1,500 years.

ARAGUAY, or *Araguaya*, a river of Brazil, rises in lat. 18° 10' S. and lon. 51° 30' W., flows northward, between the provinces of Matto Grosso and Goyaz, to São João, lat. 6° 5' S., where it unites with the Tocantins, and the combined stream discharges its waters, after a course of nearly 400 m. further, into the southern estuary of the Amazon, in lat. 1° 40' S. Its whole course is about 1,300 m., of which about 1,100 are navigable. About midway in its course it separates into two arms, which enclose the island of Banana or Santa Anna, 210 m. long and 40 broad. Its principal tributary is Das Mortes, which joins it in lat. 12° S. Many tribes of warlike savages are found on the banks of the Araguay. It furnishes an uninterrupted navigation from Pará almost to the head waters of the Paraná.

ARAKTCHEYEFF, *Alexei*, count, a Russian statesman, born in 1769, died May 3, 1834. He was of an obscure family, was educated in the military school of St. Petersburg, entered the artillery, and reached in it the highest rank. He was a favorite of Paul I., and for a short time governor general of St. Petersburg, but was dismissed on account of his insufferable harshness. Paul made him commander of his favorite regiment of guards at Gatelina, an imperial residence in the environs of the capital. Suspicious of danger, Paul the day before his murder sent an order for Arakteheyeff and his regiment. The courier was detained by the conspirators, and Arakteheyeff reached the barriers of the capital too late. Alexander, the successor of Paul, kept Arakteheyeff near his person, and he remained unshaken in his master's favor. He was energetic and active, but hard and utterly distrustful. The military col-

onies introduced into Russia under Alexander, were created and organized by Arakteheeff amid bloodshed and cruelties. During the last years of the czar's reign Arakteheeff became virtual ruler of the empire, issuing laws and ukases on blanks with the imperial signature. Soon after Alexander's death he was ordered to confine his residence to his estates at Gruzino. He left the bulk of his large fortune to a military school founded by him in Gruzino, and \$20,000 to serve, with the accumulated interest, as a prize for the best history of the reign of Alexander, 100 years after his death. It is supposed that this part of the will was annulled by Nicholas.

ARAL, Sea of, a large inland sea or lake of Asiatic Russia and Turkistan, between lat. 42° 30' and 47° N., and lon. 57° 30' and 61° 30' E. It lies about 40 feet above the ocean, and more than 100 feet above the Caspian sea, from which it is 200 m. distant at the nearest point, and with which Humboldt and others suppose it to have been formerly connected. The Aral, covering an area of about 24,000 sq. m., is, next to the Caspian, the largest inland sea of the eastern hemisphere. It is shallow, with many islands. It has no outlet, but the Sir Darya or Sihoon (the Jaxartes of the ancients), the Amu Darya or Jihoon (the Oxus), and several smaller rivers flow into it. The water is brackish, but is freely drunk by horses, and is used for culinary purposes. Fish are abundant. The navigation of the sea of Aral is exceedingly difficult for sailing vessels; perfect calms alternate with violent and sudden storms, oftenest coming from the northeast. The harbors and anchorages are few and insecure. The shores are generally low and sandy, but on the northern side are small hills of clay. Its borders are generally uninhabited in summer, but in winter they are frequented by nomadic tribes from the Kirghiz steppes. The sea of Aral is in the power of the Russian empire. The Russians explored and made a map of it as early as 1740, and they sent occasional expeditions to its borders till 1847, when they built a fort at the mouth of the Sir, and began to take military possession of the principal islands of the lake. Colonies were soon afterward founded, and Russian vessels began the regular navigation which they have since continued.

ARAM (Latinized *Aramæa*), the Hebrew name of the region lying N. and E. of Palestine and Phœnicia, and extending to the Tigris, the northern and southern boundaries never having been accurately defined. It corresponded generally to Syria and Mesopotamia of the Greeks and Romans, and included parts of Chaldea and Assyria. In the Septuagint the name is usually rendered by Syria. It means highlands, for, although most of the region is a low plain, the part which immediately borders upon Palestine is elevated. That portion between the Tigris and Euphrates is specially designated as Aram-naharain, "Aram of the two rivers," answering to the Greek *Μεσοποταμία*. Here

was the original home of Abraham, whence he migrated to Canaan. From this migration dates the long separation between the Hebrews and their Aramean kindred.—The Aramaic language remained in a rude state after the separation, while the Hebrew, which was undoubtedly at first identical with it, became greatly developed; so that in the time of Hezekiah the former was unintelligible to the mass of the Jews. When the ten tribes of Israel were carried away, their place was partly supplied by various Aramean immigrants, who gradually formed a patois designated as Galilean or Samaritan. The exiles from Judah, during their residence in Babylonia, abandoned their own language and adopted the Aramaic, which they brought back with them to Judea. This formed the current language in Palestine until it was partially superseded, after the Macedonian conquest, by the Greek. Christ and his principal disciples probably spoke both languages; they certainly spoke Aramaic. In the 7th century the Moslem invasion of Syria introduced the Arabic language, which gradually took the place of the Aramaic; and the latter has become nearly extinct, existing now as a living tongue only among the Syrian Christians near Mosul. Properly speaking, the Aramaic has no literature of its own. As a written language it has been used in its two branches, the Chaldee and Syriac, only by the Hebrews and eastern Christians, and by them only in treating of religious subjects. The canonical books of the Old Testament contain two extended passages in Chaldee (Ezra vii. 12–26; Dan. ii. 4 to vii. 28). Several of the apocryphal books were written in Aramaic, although they now exist only in the Greek translation. The versions of Hebrew Scriptures known as Targums are written in Aramaic. It is not unlikely that the Gospel of Matthew was originally written in it, although we have it authentically only in its Greek form. The Talmud, as a whole, is written in Aramaic, but with such variations from the main dialects that some have proposed to give the name Talmudic to the idiom in which it is composed. (See *CHALDEE LANGUAGE AND LITERATURE*, and *SYRIAC LANGUAGE AND LITERATURE*.)

ARAM, Eugene, an English scholar, born at Ramsgill, Yorkshire, in 1704, executed at York for murder, Aug. 6, 1759. Aram enjoyed a remarkable reputation for extensive scholarship acquired under the greatest difficulties, his father having been a poor gardener. After his marriage he established himself as a schoolmaster in his native district of Netherdale. In 1734 he removed his school to Knaresborough, where in 1745 he became implicated in a robbery committed by Daniel Clark, a shoemaker of Knaresborough; and being discharged for want of evidence, he went to London. Clark disappeared mysteriously at the same time. Aram, while employed as school usher in various towns, and in an academy at Lynn in Norfolk, pursued his favorite studies, and was

engaged in compiling a comparative lexicon of the English, Latin, Greek, Hebrew, and Celtic languages, when he was arrested on the charge of murder. Aram's wife had frequently intimated that he and a man named Houseman were privy to the mystery of Clark's disappearance. Houseman, on being pressed by the coroner, testified that Aram and a man named Ferry were the murderers, and that the body had been buried in a particular part of St. Robert's cave, a well known spot near Knaresborough. A skeleton was discovered in the exact place indicated, and Houseman's evidence led to Aram's conviction. Aram refused the services of counsel, and conducted his own defence in an elaborate and scholarly manner, making an ingenious plea of the general fallibility of circumstantial evidence, especially that connected with the discovery of human bones. After condemnation he acknowledged his guilt. On the night before the execution he attempted suicide, but was discovered before he had bled to death, and his sentence was carried into effect three days after it was pronounced. Before he attempted suicide he wrote an essay on the subject, and also a sketch of his life. Of his "Comparative Lexicon" only passages from the preface are extant. He left a widow and six children. A veil of poetry has been thrown over his fate by Thomas Hood's ballad of "The Dream of Eugene Aram," and Bulwer's romance of "Eugene Aram."

ARANDA, Pedro Pablo Abarea y Bolea, count of, a Spanish statesman, born in Saragossa in December, 1718, died in 1799. He first served in the army, but subsequently devoted himself to the civil service. After officiating for seven years as ambassador of Charles III. at the court of Poland, he was appointed commander of the army in Portugal. Here he captured Almeida in August, 1762, and was afterward appointed captain general of Valencia. In 1765, after quelling an insurrection in Madrid, he was made president of the council of Castile, and soon after prime minister. He inaugurated a new municipal system, established schools, provided Madrid with a permanent garrison, strengthened the army and navy, advanced the industrial and agricultural interests of the kingdom, and reformed the financial condition of the bank of San Carlos. He established a law which made the sanction of the council of Castile requisite for the validity of the decrees of the Vatican, opposed the inquisition, and set up a political censorship in order to neutralize its influence. By a decree of April 2, 1767, the Jesuits were expelled from Spain, and their property confiscated. The hostility of the clerical party, heightened by his confidential correspondence with Voltaire, who had urged him to persevere in his work of reform, forced him in 1773 to tender his resignation as prime minister. Accepting the post of ambassador at Paris, he became noted for his opposition to England, which had indeed always been the leading

feature of his foreign policy. He prevailed upon Charles III. to join France in supporting the cause of America, and in 1783 was one of the signers of the treaty of Paris, which recognized the independence of the United States. In 1787 he returned to Spain, and in 1792 again became prime minister as successor of Florida Blanca; but under Charles IV. he was forced to surrender the place to the queen's favorite, Godoy. On occasion of the war with France, he expressed himself against its justice, and this remark was seized upon as a pretext to banish him from the capital.

ARANJUEZ (anc. *Ara Jovis*), a town of Spain, in the province and 30 m. by railway S. of the city of Madrid, on the left bank of the Tagus; pop. 3,800. It is the site of a royal palace of great beauty founded by Philip II., a favorite retreat of the monarchs of Spain during the spring, and is well supplied with gardens, cafés, hotels, and various places of fashionable amusement. The presence of the court swells the population to about 20,000. In summer the place is not healthy.

ARANY, János, a Hungarian poet, born at Nagy-Szalonta, in the county of Bihar, in 1817. He is the son of a poor Protestant, who educated him for the church. After leaving college he roamed for a while with a troop of strolling players, and then returned to Szalonta and supported himself as a teacher of Latin. In 1843, the Kisfaludy society having offered a prize for the best popular epic, Arany won it by his poem, *Az elveszett alkotmány* ("The Lost Constitution"). In 1847 he sent to the same society the first part of his greatest production, the trilogy *Toldi*. The society gave the author more than the stipulated price, and had it printed at their expense. In February, 1848, appeared his *Murány ostroma* ("Siege of Murány"). Since 1848 his chief literary works have been *Katalin* (1850), the second part of *Toldi* (1854), two volumes of lyric poems (1857), and another trilogy, *Buda hűtálla*, the first part of which appeared in 1864.

ARAPAHOE, an E. county of Colorado territory; area, 4,600 sq. m.; pop. in 1870, 6,829. The Kansas Pacific railroad passes through the county and terminates at Denver, and is connected by a branch from that city with the Union Pacific at Cheyenne. Capital, Denver, which is also the capital of the territory.

ARAPAHOES, an Indian tribe which has for many years resided near the head waters of the Arkansas and Platte rivers. They are known also as Fall Indians, and were called by the French the Gros Ventres of the south. Gallatin supposed them to be the Querechos of early Spanish explorers in New Mexico. They style themselves Atsina. This is apparently another form of Asinais or Cenis, a confederation of tribes visited by La Salle at this point, and subsequently by Spanish missionaries and French traders. The Arapahoes, like the Asinais, are by language allied to the Caddoes. At the present time they are one of the five tribes constituting the

Blackfeet confederacy. In 1822 they were a powerful tribe estimated at 10,000, but in 1842 they had dwindled to 2,500 in 300 lodges, and, with the disappearance of the buffalo, are rapidly declining.

ARARAT (Arm. *Masis*; Turk. *Agri Dagli*), a mountain of western Asia, considered a portion of the "mountains of Ararat" on which, according to Gen. viii. 4, Noah's ark rested after the deluge. It is divided into two peaks, Great Ararat on the N. W. and Little Ararat on the S. E., whose bases blend, while their summits are nearly 7 m. apart. The summit of Great Ararat lies in lat. $39^{\circ} 42' N.$, lon. $44^{\circ} 38' E.$, and is 17,323 feet above the sea level, and 14,320 feet above its base. For more than 3,000 feet below its summit it is constantly covered with snow and ice. Little Ararat is lower by about 4,000 feet, and is free from snow and ice in September and October. The

two mountains are of volcanic character, an eruption having taken place from them as lately as July, 1840. The apex of Great Ararat was visited on Oct. 9, 1829, by Parrot. Ararat is the central point of the dividing lines of Armenia, and the great landmark between Russia, Turkey, and Persia.

ARARAT, or **Pilot Mountain**, a mountain of North Carolina, in Surrey county, between the Ararat and Dan rivers. It is of a pyramidal form and one third of a mile high; and its top is a plateau one acre in extent, on which is a gigantic rock 300 feet high.

ARAS. See **ARAXES**.

ARATUS. I. A Greek poet, born at Soli in Cilicia, flourished about 270 B. C. He was educated under Dionysius of Heraclea, a Stoic, the principles of which sect he embraced. He was a friend of Ptolemy Philadelphus, and also of Antigonus Gonatas, king of Macedon, a

Mount Ararat.

whose instigation he embodied most of the astronomical knowledge then possessed by the Greeks in two philosophical poems. The first, *Phænomena*, gave a general description of the heavenly bodies and their movements, while the second, *Diosmeia*, described their influence on the atmosphere. These poems possess much merit. Aratus is the poet whom St. Paul quotes in his speech on Mars Hill, Acts xvii. 28. The best edition of his works is by Bulile (2 vols. 8vo, Leipsic, 1793, 1801).

II. A Greek general and statesman, son of Clinias, born at Sicyon, 271 B. C., died in 213. On account of the murder of his father and many of his relatives by Abantidas, their enemy in one of the political contests of the time, he was taken while very young to Argos, where he was educated till he reached the age of 20. At this period he succeeded in carrying out,

without bloodshed, a revolution he had long plotted with some Argive friends, by which Nicocles, a usurper who had made himself tyrant of Sicyon, was dethroned and the city set free. Aratus persuaded the citizens to join the Achaean league, of which he was elected general in 245. Re-elected in 243, he captured the citadel of Corinth and expelled its Macedonian garrison. Corinth was easily induced to join the Achæans, and was soon followed by Træzen, Epidaurus, Megara, Cleonæ, Argos, and Megalopolis. He now hoped to unite all the governments of Greece; but the power of the Achaean league already began to excite the jealousy of the Ætolians, and of Cleomenes III., king of Sparta, who aspired to restore the Spartan hegemony. Its first active enemy was the latter, who began a war about 224. Aratus defeated him, but only by sum-

moning to his aid Antigonus Doseon, king of Macedon, and by taking the unfortunate step of delivering to him Corinth and its citadel as the price of his assistance. Antigonus took advantage of this offer, which at once proved fatal to the power of the Achaean cities. He became general of the league, and gradually gained complete control of it, transmitting this authority to his son Philip. Aratus remained a prominent leader in spite of the Macedonian rule; but in a new war which soon broke out with the Ætolians (221 to 219), he was unsuccessful. He was tried for neglect of duty, but acquitted in consideration of his past services. From this time he was little more than an adviser of the Macedonian king, who had now made the league completely dependent upon himself; and although appointed general for the 17th time in 217, he never attained his old influence. According to Plutarch and Polybius, whose story has been doubted by many historians, he was put to death by slow poison, given by Philip's order. The Greeks paid divine honors to his memory, and celebrated twice a year games called Arateia—one on the anniversary of his birth, and one on that of his deliverance of Sicyon.

ARAUCANIANS, an Indian nation inhabiting the provinces of Arauco and Valdivia, Chili. The name is derived from the Indian word *auca*, meaning frank, or free. As offering the most successful example of Indian self-government in the presence of the European races, the Araucanians are of interest to the philosopher and the ethnologist. The chief authority with regard to them is "Molina's History of Chili," of which an English translation was published at Middletown, Conn., in 1808. Five different poems have been written by Europeans upon their patriotic struggles against the European invaders. The best are the *Araucana* of Alonso de Ercilla, a Spanish knight of the 16th century, who took part in the wars he describes, and the *Puren Indomito* of Alvarez de Toledo (Paris, 1862). The Araucanians were first invaded by the Spaniards in 1537. Valdivia founded many settlements in their country, which with their founder were destroyed in 1602. In 1641 the marquis de Baydes made a treaty with their chief, but in 1665 war commenced again, and lasted at intervals until 1773, when Spain at length acknowledged the independence of the Araucanians, and allowed them to maintain an embassy at Santiago de Chili. In the contest between the mother country and the Chilian colonists, they preserved a strict neutrality. Schmidmeyer visited them in 1820, and published his "Travels into Chili, over the Andes," in 1820-'21. Mr. Edward Reul Smith, of the U. S. astronomical expedition in Chili, published "The Araucanians, or Notes of a Tour among the Indian Tribes of Southern Chili" (New York, 1855).—The territory of Arauco has been from time immemorial divided into four *vuthanmapus* or *uthalmapus*, or provinces, each presided over by a magistrate called a *toqui*;

these four provinces correspond to the natural divisions of the country, viz., the maritime province, the plain province, the province at the foot of the Andes, and the province in the Andes. Each of these is divided into five *illarchues*, ruled by an *apo-ulmene*, and each *illarchue* is further subdivided into nine *rehcus* or townships, over each of which presides an *ulmene*, or head of a clan. The symbol of a *toqui* is an axe of porphyry or marble; of an *apo-ulmene*, a staff with a silver head and a silver ring round the middle; of an *ulmene*, the same without the silver ring round the middle. All of these dignities are hereditary according to primogeniture. No regular tribute or any predial service is payable by the clan to the *ulmene*, by the *ulmenes* to the *apo-ulmene*, or by the *apo-ulmenes* to the *toqui*. In time of war, however, military service is acknowledged as the most sacred of duties. The four *toquis*, or governors of provinces, form the grand council of the Araucanian federation, presided over by one of its own members, the grand *toqui*. This council decides on war and peace, and on emergencies calls together the general assembly. At this diet, every *toqui*, *apo-ulmene*, and *ulmene* may attend; it chooses the commander-in-chief from among the four *toquis*; but if none of them are qualified, then from the diet at large. The levy is made by the *ulmenes* upon their several clans. The army consists of both cavalry and infantry. The *toqui* Cadegnala was the first who established a regular body of cavalry, in 1585. The diet is held in a large plain which lies between the rivers Biobio and Dunqueco. The religion of the Araucanians is akin to their political institutions. Their Supreme Being is the great *toqui* of the universe; he has his subordinate *ulmenes* to look after details. These are, the god of war, the beneficent god, the god of mankind, and others. Guecubu is the god of evil. The celestials exact no tribute from their subjects here below; therefore the Araucanian builds no temples nor idols, supports no priests, and rarely offers sacrifice. After the death of the body, the soul goes into paradise, a region which lies on the other side of the Andes. Their religion, in other respects, resembles other primitive creeds. They hate the Spanish language, and their *toquis*, though well acquainted with it, will never use it on any public occasion. They make a foreigner take an Araucanian name before he is allowed to settle among them. A missionary, when preaching to them, is often interrupted in the midst of his discourse, if he commits a blunder. The Araucanians are stoutly built, and of moderate height. Their complexion is olive, and lighter than the other South American Indians; they have a round face, low forehead, short, broad nose, small, fiery eyes, small lips, and long head. The women do all the home and field work; the men hunt, fight, and tend the flocks. They live in wooden or reed plastered houses, well built, and often 60 feet by 25 in

size, not in villages, but in the centre of their plantations. They raise wheat, maize, and barley, peas and beans, potatoes, cabbages, and fruit, as well as flax, and keep numbers of cattle and horses. Before the arrival of the Europeans they wove ponchos and coarse woollen cloths of very good workmanship. Their language is very wide-spread, and had nine recognized dialects. It was spoken from lat. 25° S. to Cape Horn, and eastward to Buenos Ayres. The best grammar is the Chilian grammar of Febres (Lima, 1765; Santiago, 1846). Molina's account has been accused of exaggeration, and may be compared with the works of Gilj, Ilavestadt, Falkner, &c.—In 1861 a Frenchman named De Tonneins, having ingratiated himself with the tribes, was proclaimed king of Araucania under the title of Orélie Antoine I. He was soon at war with Chili, and was captured in January, 1862, on Araucanian territory. The arrest was pronounced illegal, but the Chilian government held him some time as a lunatic, permitting him finally to go to France, where the validity of his regal title was formally recognized in the course of a lawsuit. He published *Orélie-Antoine I^{er}, roi d'Araucanie et de Patagonie, et sa captivité au Chili* (1863). He afterward returned to Araucania, and in 1869–70 was again at war with Chili; but in 1871 he was once more in France, and began publishing an official Araucanian journal at Marseilles, striking medals, establishing orders of knighthood, &c. He left in Araucania a deputy, one Planchut, who soon usurped the regal title.

ARAUCO, a southern province of Chili, divided into the three departments of Arauco, Laja, and Nacimiento; area, 13,500 sq. m.; pop. in 1868, 82,709, besides some 35,000 Indians. Capital, Arauco, on a bay of the same name, 300 m. S. of Valparaiso. This province was created by decree of Dec. 7, 1852; but the Araucanian Indians still maintain their independence in the interior.

ARAXES (now *Aras*), a river in Armenia, rising about 25 m. from Erzerum, in lat. 41° 30' N., lon. 41° 10' E., between the E. and W. branches of the Euphrates. It flows E., S. E., and N. E., and after a course of about 425 m. unites with the Kur about 75 m. from its mouth in the Caspian. It is notable for the impetuosity of its current. Virgil describes it as "disdaining a bridge," but it is now crossed by four stone bridges. There can be little doubt that the Aras is the river descended by Herodotus under the name of Araxes, although Rennell thinks the Jaxartes was meant; and it has been supposed also to be the Oxus, and even the Volga. By Araxes Xenophon probably intended the Chaboras, an affluent of the Euphrates.—The river now known as the Bendamir was also called Araxes. It rises in central Persia, flows past the ruins of Persepolis, and after a course of about 150 m. falls into the salt lake of Bakhtegan or Negris, in lat. 29° 30' N., lon. 52° 30' E.

ARBACES, the founder of the Median empire, according to Ctesias, who asserts that Arbaces, jointly with Belesis of Babylon, captured Nineveh and overthrew the empire of Sardanapalus (876 B. C.), that he reigned 28 years, and that his dynasty numbered eight kings. These statements differ from those of Herodotus.

ARBALAST, or **Crossbow**. See **ARCHERY**.

ARBELA, the ancient name of Arbil or Erbil, a small village in Turkish Kurdistan, which lies on the usual route between Bagdad and Mosul, about 40 m. E. by S. of the latter city, in lat. 36° 11' N., according to the elder Niebuhr's observations. The third and last of the great battles between Alexander and Darius (331 B. C.) is called after this place, though it was not actually fought at Arbela, but at a place 36 m. W. by N. called Gangamela, now Karmeliss.

ARBITER, a Roman umpire, chosen by an agreement (in the Roman law *compromissum*) between contending parties, to decide their differences. His decision was called the *arbitrium*. Such a judge, chosen by the parties themselves, was an *arbiter receptus*. An *arbiter datus* was appointed by the praetor to decide in matters purely of equity, while the *judex* decided in matters of law and precedent. The duties and rights of these officers, with the extent to which the decisions of an arbiter could be enforced, were sharply defined by the Roman law.

ARBITRATION, the decision by a private person of matters of difference submitted to him by the parties. References differ from arbitrations in that they are made with the sanction of the court, or at least are more directly under its control and are governed by the rules of law more strictly than arbitrations are. The law is not disposed to take away the ordinary means of relief by action or other proceedings at law, unless suitors have clearly signified their intention to give them up in favor of arbitration. The New York court of appeals has held void an article of the constitution of a grand lodge of odd fellows, which created certain members a tribunal to pass upon violations of the rules of the order, with power to forfeit the delinquents' right to property. Even if the defendants had signed such a constitution, the court said it would be against public policy to hold them bound by it, and that courts would not enforce the decision of tribunals created by private compact, except in those cases where the parties had expressly submitted to arbitration definite matters of controversy. In a recent case in New York city, the court held that the so-called "arbitration clause" in the articles of association of the board of brokers could have no other effect than an ordinary agreement to submit; and the court declined to give a remedy against a member of the board who declined to submit to its jurisdiction, for that was only the exercise of the ordinary power of revocation.—As a general rule, all matters in dispute concerning personal rights which may be the subject of actions may be referred to

arbitration; such, for example, as breaches of contracts, differences about partnership affairs, the value of property, and questions of damages in cases of wrongs like assaults, trespass, or slander, where damages might be recovered by suit. Claims relating to real estate might at common law be submitted to arbitration. In such a case an arbitrator might direct that one party convey or release to the other. But a practical objection to this proceeding, so far at least as titles to land are concerned, is that the property in the land cannot pass by the award. In some of the states the statutes relating to arbitrations forbid the submission of certain matters pertaining to real estate. Thus in New York no submission can be made of claims to the fee or to life estates in realty; but the same restraint is not imposed as to interests in terms for years, nor to controversies as to boundaries, partitions, or the measurement of dower. Nor are equitable rights relating to real estate withdrawn from arbitration. The policy of the statute in these respects has been said in New York to be to withdraw from the unlearned forum of arbitration those questions of title to lands which depend on strict technical rules; and that, since equitable claims even in respect to titles depend rather on the general principles of justice, they may be well submitted.—In general, a crime cannot be withdrawn from the cognizance of the courts. But where a person has a remedy by action for private damages, collateral to the public remedy by indictment, as in cases of assault, libel, or nuisance, he may submit the question of his personal interests to arbitrators.—Persons who are competent to contract are also capable of submitting their affairs to arbitration. It was the general rule at common law that married women could not make a submission, though there were exceptions to that rule in favor of women whose husbands were civilly dead or alien enemies. But since the enabling acts which have been lately very generally introduced, giving to married women separate estates, and independent powers and capacity to contract in respect to them, they have been held capable of consenting to arbitrations. An infant's submission is at common law, like most of his contracts, voidable by him. But it has been held with regard to such agreements of infants, and of married women too, who had not the liberty of contracting which is conferred by the recent married women's acts, that if an award is made against a party who entered into an arbitration with either of them, it will bind him, even though the woman or the infant cannot be held by it, because he must be presumed to have known that at the outset, and if he did not intend to be bound, he should not have joined in the submission. Whether one partner can bind his copartners by an agreement to arbitrate has been much discussed, and the weight of authority seems to be against his power to do so. But such an agreement may bind the

partner who made it, and he may be held for the damages resulting from the refusal of his copartners to perform the award.—In the absence of statutes to the contrary, the submission need not be in any special form, nor even in writing. But in most of the states, under the statutes on the subject, a submission may be made a rule of court; that is to say, the parties may agree that the proceeding be entered of record in a court, and then the award upon confirmation has the effect of a judgment of that court, and may be enforced with the same legal remedies provided for judgments. These statutes require the submission to be in writing and executed with certain formalities. The statutes usually require that the arbitrators shall be sworn, and that the witnesses shall be sworn also, either by them or by justices of the peace or other competent persons; and that the attendance of witnesses may be compelled by subpoenas issued either by the arbitrators themselves or by justices or other judicial officers. But it has been held in New York, though its statute requires the arbitrator to be sworn, that this is not an essential prerequisite to his jurisdiction, and that the omission of the oath is only an irregularity. When the submission provides for the appointment of an umpire by the arbitrators to decide between them if they disagree, this third person should be agreed upon before proceeding with the arbitration.—The hearings by the arbitrators should be on notice to both parties; and if they proceed *ex parte* and without notice to the party against whom the award is made, it is void. All the arbitrators must concur in the award, unless it is otherwise provided by statute or by the submission; and when it is provided that, in case of their disagreement, the decision of the umpire shall be final, the award should in case of such a reference to the umpire proceed from him and be signed by him. The award must dispose of all the questions contained in the submission, and must conform to its terms in all respects. If it includes matters not covered by the submission, it will be good for so much as is authorized by it, if that part can be separated from the rest; but if it departs essentially and incurably from the submission, it is fatally bad. The award must be certain in its terms; that is, it must inform each party precisely what he is to do. It must also be final and conclusive in all respects.—The statutes of the several states usually define the grounds on which awards may be set aside. In New York they may be vacated, on application to the court, for corruption or fraud or partiality on the part of the arbitrators; or if they were guilty of misconduct in refusing postponements, or in rejecting proper evidence, or exceeded their powers or imperfectly executed them in material points. And in the same state awards may be corrected for evident mistakes or for other imperfections. Very similar statutory provisions exist in Illinois, Missouri, and other

states. In several of the states it is also provided that an award may be vacated by the courts for any legal defects appearing on its face.—The chief vice or weakness in the proceeding by arbitration is the power which either party has to revoke the authority given by him to the arbitrators. The only practical penalty for such a breach of the agreement, and even when there are bonds fixing precise sums by way of liquidated damages, is that the party who revokes must pay the expenses incurred by the other up to the revocation. In some of the states, as in Massachusetts and Maine, the statutes provide that neither party shall revoke the submission without the consent of the other. But in other states, as in New York and Missouri, the only restraint is, that no revocation shall be made after the cause is finally submitted to the arbitrators upon the evidence. The death of a party pending the proceedings operates as a revocation, unless it be expressly provided otherwise by the submission, or, as is the case in some of the states, by statute.—A submission suspends, and an award bars, the right of suit on the original cause of action. The award must be made within the time directed by the agreement, and it is a nullity if made after that time, unless the parties consent to an extension of the time. The power of the arbitrators is exhausted by delivery of the award, and though in making it they have exceeded their powers or otherwise erred, they cannot recall it or make another one. The courts have repeatedly held that when not limited by the terms of the submission, the decisions of the arbitrators upon law and fact alike, provided that they act within the scope of their authority, are conclusive. If the award is within the submission, and contains an honest and fair decision, a court of equity will not set it aside for error either in law or in fact. Judge Story and other high judicial authorities have further declared that arbitrators are not bound to award upon the mere dry principles of law applicable to the case before them, but may make their award upon principles of equity and good conscience. On the other hand, if the submission expressly provides that the case shall be decided according to the law, and the arbitrators make a mistake in that respect, this will subject the finding to revision by a court. In Pennsylvania, under a statute enacted in 1836, either party to a civil action may compel a submission of it to arbitrators by filing a rule in the prothonotary's office calling for such a reference, and by serving a copy of the rule on his opponent. The number of the arbitrators, three or five or one, is fixed by the parties, or, if they cannot agree, by the prothonotary. The parties then by alternate nominations select the arbitrators; but if they cannot agree upon these, the prothonotary makes up a list containing five names for each of the number of the arbitrators, from which the parties alternately select the requisite number.—In England a statute

of 1867 provides for councils of conciliation and arbitration, which may be formed by masters and their workmen. These councils exercise powers granted by former statutes of similar tenor (1 Victoria, ch. 67, and 8 and 9 Victoria, ch. 77, 128), and by the present statute are authorized to hear and determine all questions of dispute and difference between the workmen and their masters; and their awards are final and not subject to review or challenge in any court. No attorneys, solicitors, or counsel are allowed to attend any hearing before the councils, without the consent of both sides. The courts of *prudhommes* are courts of a similar sort in France. They are established in Paris and Lyons and some of the other large cities, and take cognizance of disputes between master manufacturers and their workmen, and between workmen and their apprentices. The court is composed of master workmen or manufacturers and of foremen, six of each, one half of the number going out each year. The court acts first as a court of conciliation; and if it fails to bring the parties to an agreement, it has jurisdiction to the amount of 200 francs without appeal, and to any higher amount subject to appeals to a tribunal of commerce. It is said that almost all the cases brought before these courts are settled by conciliation.

ARBLAY, Madame d' (FRANCES BURNEY), an English novelist, daughter of Charles Burney, born at Lynn in June, 1752, died Jan. 6, 1840. In her childhood she was silent and timid, and was considered uncommonly dull. In 1760 her father removed to London, and was much sought as a music teacher. After her mother's early death Frances was left to educate herself. Dr. Johnson was her father's friend, and Garrick his frequent guest, and the brilliant social circle in which he moved afforded rich material for genius to work upon. Miss Burney soon gave evidence that she rightly appreciated her privileges. In 1778 her novel "Evelina" was published, under an assumed name, by a Mr. Lowndes, who gave her £20 for the copyright. Though the author of the book was unknown, and the publisher was not eminent, its success was marvellous, and Miss Burney was at once classed among the first writers of fiction. "Evelina" was followed by a comedy, "The Witlings," which was never acted, nor even printed, and in 1782 appeared the novel of "Cecilia," which was successful. Three years after this she was appointed keeper of the queen's robes. After five years' service she resigned this post on account of her failing health, and in 1793 married Alexandre Richard d'Arblay, a French artillery officer, whom the revolution had made an exile. In 1796 "Camilia" was published in five volumes, bringing the author a handsome sum of money, but no increase of fame. Ten years, 1802-12, she passed in Paris, her husband having given in his allegiance to Napoleon's government. At the expiration of this term she returned alone

to England and produced another novel in five volumes, "The Wanderer," which had little popularity, and is now almost forgotten. At the peace her husband, now Gen. d'Arblay, joined her, and remained with her till his death, at Bath, in 1818. In 1832 Madame d'Arblay published the memoirs of her father, written in a turgid style, entirely at variance with her earlier diction. This was the closing work of her long life, which ended when she was 87 years old. The literary fame of Madame d'Arblay rests upon "Evelina" and "Cecilia," her earliest works.

ARBOGAST (ARBOGASTES), a Gaul in the military service of the Romans during the latter half of the 4th century. In 388 he accompanied Theodosius on his expedition to support Valentinian II. against the usurper Maximus. After the revolt was reduced, Arbogast, by the order of Theodosius, remained with Valentinian as adviser; and when the latter attempted to recover his independence, Arbogast put to death all his partisans, and finally the emperor himself. Not daring to seize upon the imperial purple, he gave it to Eugenius, going himself to fight against Marcomir, chief of the Franks. Theodosius marched into Italy to avenge his cousin, and Arbogast and Eugenius were defeated in the passes of the Julian Alps, in 394. Eugenius was captured and executed. Arbogast escaped into the mountains, but soon despairing, committed suicide.

ARBOIS, a town of France, in the department of Jura, situated in the deep valley of the Cuisance, 25 m. N. E. of Lons-le-Saulnier; pop. in 1866, 5,895. The town has a college, and produces a noted wine.

ARBOR VITÆ, a coniferous tree (*Thuja*), with compressed evergreen foliage forming flattened branches, strongly aromatic. Varieties are

American Arbor Vitæ.

found throughout the northern temperate regions of both continents. The tree bears pruning well, and may be trimmed into conical or pyramidal standards, or worked into an excel-

lent hedge. In its wild state the American arbor vite (*T. occidentalis*) has loose spreading branches when growing on the edges of streams, but it becomes bushy in cultivation. Its height varies from 20 to 50 feet, and it is one of the largest of all the species. The Chinese, Nepaulese, Siberian, and Tartarean are all beautiful varieties and easily cultivated, although in northern New England they are apt to lose their branches by frost. The *Thuja plicata* is a curious variety from Nootka sound, with singular foliage. The cone of *Thuja* is small, and in ripening assumes a vertical position on the branches.

ARBRISSEL, Robert of, founder of the order of Fontevrault, born at Arbrissel, Brittany, in 1047, died at Orsan in 1117. In 1085, upon his appointment as vicar general of the bishop of Rennes, he began sweeping reforms among the clergy and people of the diocese, which brought him into such bad odor that upon the death of his superior in 1089 he retired to Angers and gave instructions in theology. At the expiration of two years, disgusted with the world, he retired into the forest of Craon, where he lived as a hermit. Numerous anchorites soon placed themselves under his direction, and he gave his followers the name of "The Poor of Christ." In 1096 he founded the abbey of La Roe, of which he became the first prior, but soon relinquished this peaceful life to travel barefooted through the country, preaching repentance and penance to the people. He soon had several thousand followers of both sexes, for whose accommodation he built a number of abbeys, the most celebrated of which is that of Fontevrault, near Poitiers, established in 1099.

ARBROATH, Aberbrothwick, or Aberbrothock, a royal and municipal burgh of Forfarshire, Scotland, on the North sea, at the mouth of the Brothwick or Brothock, 58 m. N. N. E. of Edinburgh; pop. in 1871, 19,974. The town has a signal tower communicating with the Bell Rock lighthouse, which has been celebrated by Southey as the Inch Cape Rock under the pious care of the abbot of Aberbrothock. The once powerful abbey of Arbroath, founded in 1178 by William the Lion, who is buried here, in honor of Thomas à Becket, was destroyed by the reformers in 1560. All that remains of it is the ruined church with its cloisters, and an east window with a circular light at the top, a conspicuous mark for sailors, who call it the "round O of Arbroath." The small harbor is protected by a breakwater. Between 400 and 500 vessels enter and leave the port annually, with between 30,000 and 40,000 tons. There are four annual fairs and a weekly market. The imports are tallow, flax, hemp, and linseed; the exports grain, paving stones, and the local manufactures of sailcloth, thread, and leather.

ARBUTHNOT, John, a Scottish physician and writer, born in Kincardineshire about 1675, died in London, Feb. 27, 1735. He was the son of a Presbyterian clergyman, took his doc-

tor's degree at the university of Aberdeen, and going to London, supported himself for a while by teaching mathematics. He made his first literary venture in 1697 in a critical essay entitled "An Examination of Dr. Woodward's Account of the Deluge," in which he aimed to show that a universal deluge was inconsistent with philosophical truth. The reputation which this work gave its author was considerably heightened in 1700 by his "Essay on the Usefulness of Mathematical Learning." He now began to practise as a physician, and quickly attained a high position in the profession, aided not a little by his witty conversation and agreeable manners. In 1704 he contributed to the royal society a paper concerning the regularity of the birth of both sexes, which procured his election into that body. In 1709 he was appointed the queen's physician in ordinary, and the next year was admitted a member of the royal college of physicians. He lived in constant intercourse with Pope, Swift, Gay, Parnell, Gray, and Prior, in whose brilliant circle he was unequalled for learning and wit. In 1712 he wrote the "History of John Bull," a political allegory, designed to ridicule the duke of Marlborough and render the war unpopular. It is the most durable monument of his fame, and one of the best humorous compositions in the English language. He formed in 1714, in conjunction with Swift and Pope, the plan of writing a satire on the abuse of human learning in every branch. The design was to be executed in the humorous manner of Cervantes, in the form of a history of feigned adventures. It was frustrated by the death of Queen Anne, by which Arbuthnot lost his place, and a serious blow was given to all the political friends of the associated wits. The design was never carried further than an imperfect though witty and original essay, written chiefly by Arbuthnot, under the title of "First Book of the Memoirs of Martinus Scriblerus." Dr. Arbuthnot visited Paris immediately after the death of the queen, and on his return continued his literary occupations and his medical practice. In 1717 he and Pope gave assistance to Gay in a farce entitled "Three Hours after Marriage," the failure of which is explained in part by the peculiar character of Arbuthnot's humor, which was something too refined and rare to be generally appreciated. In 1723 he was chosen second censor of the royal college of physicians, and in 1727 was made an elect of the college, and pronounced the Harveian oration. In 1727 also appeared the most valuable of his serious performances, entitled "Tables of Ancient Coins, Weights, and Measures." He continued to write humorous papers, among them a remarkable epitaph upon the infamous Col. Charteris. In 1732 he contributed toward detecting and punishing the impositions of the so-called "Charitable Corporation," and shortly afterward published his essays concerning "The Nature and Choice of Aliments," and "The Effects of Air on Human Bodies." He was

then living in great debility at Hempstead, and, failing to obtain relief, returned but a short time before his death to London. His last humorous work was an entertaining and scholar-like paper on "The Alteration or Scolding of the Ancients." Arbuthnot was equally admired for his amiability and his wit. Some of his writings are so blended with those of his confederates that they are not easily distinguished.

ARBUTUS, a genus of evergreen shrubs belonging to the natural order *Ericaceæ*. The fruit is a berry containing many seeds. The most remarkable species of this genus is the arbutus of Virgil, called the *A. unedo*, or the strawberry tree, the berries of which bear a strong resemblance to the common strawberry. It is a native of the south of Europe and the Levant. In northern Europe it is a hardy evergreen, sometimes attaining to a height of 20 feet, bearing greenish-yellow blossoms in October and November, and bright yellow and red berries in November and the following

Arbutus unedo, or Strawberry Tree.

months. At the lake of Killarney in Ireland there are beautiful groves of this species of arbutus, which give a charming aspect to the country. Its berries, if eaten freely, are apt to produce stupefaction. In Corsica a pleasant wine is said to be prepared from them. Its bark and leaves are astringent. The oriental arbutus, *A. andrachne*, is a native of the Levant, and has similar narcotic qualities. It is superior in beauty, but much less hardy in cold climates, not bearing fruit in northern Europe. Its leaves are broader and less serrated; its bark peels off so as to leave the stem always smooth, and of a clear bright cinnamon-brown color. The mule arbutus, *A. hybrida*, apparently a cross between these two, has great beauty of foliage, and in moderately cold regions grows well, but does not bear berries in northern Europe. *A. procera* is a native of California, cultivated as an ornamental evergreen in the gardens of Great Britain.—The trailing arbutus (*epigæa repens*) is

a plant of the same order, but of a different genus. It takes its generic name (Gr. *ἐπί* and *ῥῆ*, upon the ground) from its trailing lowly habit, and its common name Mayflower from

Trailing Arbutus (*Epigaea repens*).

the season of its blossoming. The leaves are alternate, coriaceous, and evergreen; the stems and other portions of the plant are covered with reddish, bristling hairs; and the cluster of very fragrant white or pink flowers appears in the axils of last year's leaves. It is found throughout New England, especially near the coast, on the edges of pine forests, and it also grows in great perfection in the valley of the Connecticut. It is also called ground laurel.

ARC (Lat. *arcus*, a bow), the name of any portion of a curved line; thus, an arc of a circle is a portion of the circumference. To rectify an arc is to give the length of the straight line to which it would be equal if it were made to have the same length in a right direction which it now has in a curved. Two arcs are said to be equal when, being rectified, they have the same length; and similar when, being taken from different circles, they have the same number of degrees—that is, are equal fractions of their respective circumferences. The arcs of a circle serve to measure the angles (see **ANGLE**); if from the vertex of the angle as a centre, with whatever radius, a circumference be described, the number of degrees of the arc intercepted between the two lines which form the angle will be the measure of the angle. Thus, for instance, as the arc of 90° corresponds to a right angle, if we find that the intercepted arc contains 15° , we conclude that the angle is to a right angle in the ratio of 15° to 90° , or that it is the sixth part of a right angle. The chord of an arc is the right line which joins its extremities; a segment is the area included between an arc and its chord; and a sector is the area included between an arc and the two radii going from its extremities to the centre of the circle.

ARC, Joan of. See **JOAN OF ARC**.

ARCACHON, a village of France, in the department of Gironde, 35 m. by railway W. S. W. of Bordeaux; pop. about 2,000. It is situated on a landlocked bay or lake (*bassin d'Arcachon*), about 60 m. in circumference, connected with the gulf of Gascony by a narrow strait. Since 1854 the village has been converted into a watering place by the Pécere family, who bought the surrounding woods and swamps, and drained part of the bay. Previous to the Franco-German war the visitors annually averaged 5,000. Persons suffering from diseased lungs are much benefited in winter by the mildness of the climate. The beach is very fine, and sea bathing attracts in summer many visitors. The pine woods extend almost as far as Bayonne, and abound with game.

ARCADIA, the central and, next to Laconia, largest of the ancient divisions of the Peloponnesus; area about 1,700 sq. m. It included the most picturesque and beautiful portion of Greece. The country embraced by its ancient boundaries is mountainous, with many forests, but it contains also rich meadow lands, and rivers and brooks abound. Mount Cyllene in the northeast, Erymanthus in the northwest, and Lycaeus in the southwest, are some of its mountains most frequently mentioned by the ancients. The Alpheus was its principal stream, and Stymphalis its largest lake. It had neither seaports nor navigable rivers. Pausanias says its name was derived from that of Arcas, son of Callisto. In the most ancient times its inhabitants, of Pelasgic origin, were hunters and rough shepherds; but they gradually turned their attention to agriculture and to raising cattle. Their habits were simple, and the quiet and happiness of their life among the mountains, their fondness for music and dancing, their hospitality and pastoral customs, made the Arcadians pass among the ancients for favorites of the gods. Pan and Diana were their principal deities. The poets have chosen Arcadia for the scene of many idyls, until its name has become the synonyme for a land of peace, simple pleasures, and untroubled quiet. In spite of this the Arcadians were, like nearly all mountain races, a brave and martial people, and, though they produced no great military leaders, were almost constantly engaged in war, either on their own account or as the mercenaries of others, fighting bravely even against their own countrymen for those who hired them. They fought in the ranks of both contending parties in the Peloponnesian war, and at the battle of Issus thousands of them were slain in the army of Darius, by Alexander. The principal cities of Arcadia—Mantineia, Tegea, and Orchomenus—engaged in frequent and injurious disputes among themselves. Against the Spartans the Arcadians (about 370 B. C.) built the city of Megalopolis, and organized a general assembly. They subsequently became confederates in the Achaean league, and on its final defeat in 146 B. C. fell

under the Roman power. Thenceforth they have no separate history from that of the empire, and of mediæval and modern Greece.—At present Arcadia, comprising the larger part of the ancient division, with the addition of the ancient district of Cynuria and a part of Laconia, forms one of the nomarchies of the kingdom of Greece, bounded E. in part by the gulf of Nauplia; area, 2,028 sq. m.; pop. in 1870, 131,740. Capital, Tripolitza.

ARCADIUS, the first of the Byzantine emperors, born in Spain, A. D. 383, died in Constantinople, May 1, 408. He was the elder son of Theodosius the Great, the last ruler of the whole Roman empire. In 395, a few months before his death, Theodosius divided the empire between his two sons, Arcadius and Honorius, giving to the former the eastern part, extending from the Adriatic to the Tigris and from Scythia to Ethiopia. Arcadius ruled at first under the regency of Rufinus, who was soon assassinated at the instigation of his rival, Stilicho, the regent of Honorius. Eutropius, a eunuch, afterward became regent, and held the place till 399, when Tribigild, a Gothic chief in Phrygia, revolted and compelled Arcadius to put his favorite to death. Tribigild and his tribe also obtained permission to pass the Bosphorus and settle on the European side; but being Arians, they were massacred or driven out by the people of Constantinople. In revenge for this the empress Eudoxia, who had now acquired the absolute control over her husband, caused Chrysostom, the great adversary of Arianism, to be banished to Comana in Pontus (404). Arcadius was a contemptibly feeble man, but of strict religious orthodoxy.

ARCESILAUS, a Greek philosopher, the founder of the Middle Academy, born at Pitane in Æolis about 316 B. C., died about 241. He was originally intended for a rhetorician, but while pursuing his studies at Athens decided to devote himself entirely to philosophy, and succeeded Crates in the chair of the academy of Athens. From the little we know of his opinions, it seems that he was a skeptic, but not in the Pyrrhonic sense of that term; and his celebrated saying, "that he knew nothing, not even his own ignorance," seems to have been but an utterance of humility. He was also distinguished from the pure Pyrrhonists by his predilection for questions appertaining to practical life, and by the undeviating moderation of his tone.

ARCH (Lat. *arcus*, a bow), a curved structure supported by its own curve. An arch is distinguished from a vault by its length being much less than its width, as is the case with the arch forming the roof of a door or of a window; but this distinction does not apply to structures built entirely above ground and open on both sides, as the arch of a bridge or a triumphal arch. It was long supposed that domes were unknown to the Egyptians and early Greeks, the first arched monument on record being the *cloaca maxima* of Rome, built

in the age of the Tarquins; but it is now certain that arches were used by the Assyrians and Babylonians long before the foundation of Rome, and also that the Egyptians were acquainted with the principle of the arch, though they did not see fit to make use of it to any great extent.—The earliest arches in Italy were built by the Etruscans. The original Etruscan dome was supported by a few pillars, under which stood the augurs; the object was to protect the priest against the sun and rain, and at the same time allow him to study the horizon and be seen by the people. The Romans scarcely deviated from the semicircle, which is the simplest form of the arch, and in building it did not follow true mechanical principles; so that the great strength of their numerous aqueducts, viaducts, and monuments is to be ascribed to their massiveness and to the good cement employed. It was not till the middle ages that the arch was properly built and widely used. Strong abutments are generally found around the monuments of that period, which consist of a succession of arches built one above the other, from the ground to the top of the monument, the uppermost one being used as an aqueduct for the roof gutters, appearing from below as light as if made of tin plate. The roofs of many of these edifices are formed of large arches as main ribs, which sustain smaller arches abutting on them; they are as slender as possible, and so appropriately shaped and ornamented as to appear much lighter than they are. The wedge-shaped stones of which an arch is composed are called voussoirs; the uppermost is the keystone; the two blocks of masonry on which the arch rests are the abutments; the line from which the arch springs is called impost; the inner curve, intrados or soffit; the curve outside the voussoirs, extrados; the span is the distance between the piers; the distance of the keystone above the impost is the height of the arch. The names of the parts of the arch proper are, the springs of the arch, the haunches, and the crown. When the arch has only to support itself, each voussoir sustains the weight of those placed above it, and consequently they must be made larger and larger from the crown to the spring; but when the arch has to support weights, the various modes in which they may be disposed require as many different constructions, and the finding of the resulting force acting on each part is one of the most difficult tasks of the architect. The use of arches in the form of an arc smaller than a semicircle is comparatively recent, and superior for many purposes to older forms. In bridges, for example, it leaves in ordinary times a larger passage for boats, and in times of freshet offers less resistance to the water, and the bridge runs less risk of being carried down. Since the introduction of cast iron in architecture, arches of that metal and of a single piece have been built; in such cases the arch is used only to please the sight, as the solidity of the struc-

ture depends entirely on other portions of the work.—A triumphal arch is a monumental structure erected in honor of some celebrated person and his deeds, or to commemorate some great event. Triumphal arches probably originated with the Romans, and L. Stertinius is the first recorded who erected such a monument. Two were built by him, one about 196 B. C. in the Forum Boarium, and another in the Circus Maximus. A few years later, Scipio Africanus built one on the Clivus Capitolinus, and in 121 Q. Fabius Maximus erected one on the Via Sacra. Of these none remain. Different writers record 21 as having been built in the city of Rome. The most celebrated Roman arches are those of Augustus at Rimini, of Trajan at Beneventum and Ancona, and those of Titus, Drusus, Septimius Severus, and Constantine at Rome. That of Titus is one of the best. It is situated at the foot of the Palatine, and was probably completed after his death and apotheosis, as in the inscription he is called Divus. It commemorates his conquest of Judea. Remains of Roman arches are to be seen in Spain, Greece, and other countries. The custom of raising magnificent triumphal arches began under the first emperors. During the republic arches were decreed to victorious generals, but not to the dead. When Augustus was emperor, the senate proposed to have one built in honor of Drusus the elder, who died in Germany. Augustus consented, and a marble arch was constructed on the Appian Way.—Paris, of all modern cities, has the most numerous and the most beautiful arches. The Portes St. Denis and St. Martin were erected in 1673-4; the arc du Carrousel in the years 1806-9, in honor of the armies of France. The latter is at the W. entrance of the Tuileries; its height is 47 feet, its breadth 55. Its two principal faces have each eight Corinthian columns, surmounted by statues. The most magnificent is the arc de l'Étoile, at the extremity of the avenue des Champs Élysées, built for the purpose of commemorating the victories of Napoleon. (See PARIS.) The arch at Hyde Park corner, with the equestrian statue of the duke of Wellington, and Cumberland gate, are the only specimens in England.

ARCHEOLOGY (Gr. ἀρχαία, ancient things, and λόγος, discourse), the science of antiquities, and especially of human antiquities in general. The primeval period of man has been divided into the stone, the bronze, and the iron ages. Sir John Lubbock, in his "Introduction" to Nilsson's "Primitive Inhabitants of Scandinavia," subdivides the stone age into the palæolithic and neolithic, the former the older and the one in which the stone implements are not polished, as they are in the latter. The antiquities of this epoch are found in beds of loam and gravel extending along the river valleys of central Europe (the *loess*), sometimes 200 feet above the present water level; they were evidently deposited by existing rivers, which ran then as now and drained the same

areas; they contain no marine remains, and each valley is characterized by fragments of the rocks in its special area. The geography of western Europe was very much the same as now, the only variations being in the ever-changing coast line and the depths of the river valleys. The animals then living were the hairy mammoth, woolly rhinoceros, hippopotamus, and most of the existing mammals, especially tigers, hyænas, and bears, ruminants and rodents, of very great size. The climate was then colder than now, as the musk ox, woolly pachyderms, reindeer, and lemming extended to the south of France. It must have taken a very long time for the extinction of these large mammalia; there is not the most vague tradition of their presence in western Europe, and there are no marks of sudden destructive cataclysms. It must have required many centuries for rivers to excavate their valleys more than 200 feet. The presence of man is indicated at this period in western Europe by his bones and implements of unpolished flint, without pottery or any of the metals; similar implements have been found in the caves of France and Spain. (See **BOXE CAVES**.) From all the evidence collected by the above-named authors, it would seem that the people then living in the south of France resembled the Esquimaux of the present day, their chief food being the flesh of the reindeer; they were ingenious workers in flint, bone, and horn, and fond of making rude drawings on the horn of the mammoth and other existing animals. A cold climate is also indicated by their habit of allowing bones and offal to accumulate in and near their cave dwellings. The cave period is probably less ancient than the gravel epoch, and, from the abundance of their remains, is often called the "reindeer" period. In the *Reliquie Aquitanica*, by Messrs. Lartet and Christy, there is a full account of the archaeology of the old stone age, as exhibited in the south of France, especially in the caves in the valley of the Dordogne and of Cro-Magnon and Moustier. These caves belong to the age of simply worked stone, without the accompaniment of domestic animals or implements of polished stone; bones of the reindeer are abundant, and the coexistence of man with this animal in latitudes so much lower than its present habitat implies a certain degree of elevation above savages, as not only food, clothing, and implements, but materials for ornamentation were obtained from it. In the earlier gravel period, the mammoth, rhinoceros, horse, and ox predominate, the reindeer prevailing in the Dordogne caves, but in neither are found remains of the dog, goat, and sheep; the same is true of the gravels and caves in England, in central France, and in South Wales. Birds and fishes, especially the salmon, were eaten; and everything shows that food was not so scarce as to demand any struggle for existence. The domestic economy of these early races is shown by their hearths, boiling

stones, rough hammers, and hollowed dish-like pebbles; there is a total absence of pottery. The remarkable similarity of the stone implements from different parts of the world is worthy of notice; this form of primitive industry has been traced in Europe from Greece to Scandinavia, and from the Atlantic coast to the steppes of Russia; in Asia, it appears from Palestine to the Malay archipelago, in India and Japan, and on the shores of the Arctic ocean; in America, from Behring strait to the plateau of Mexico, from Colombia to the Atlantic, from Peru to Tierra del Fuego, along the valley of the Amazon and its tributaries, in central Brazil, and in the West Indies; and the ancient weapons resemble those now used by the natives of New Caledonia and the Esquimaux. M. Pruner-Bey, from the examination of skeletons found in the cave of Cro-Magnon, maintains that the crania of the reindeer age, which he calls Mongoloid, belong to a double series, one approaching the Lapp and the other the Finn of the present day; the skulls of the Dordogne caves, different from both these, he refers to the Estonian type. From the low and projecting bony palate, he thinks the language of the cave dwellers was neither Aryan nor Semitic, but analogous to that of the Finnish races. He concludes that they had massive bones, long and flat feet, comparatively short arms and long forearms, with powerful muscles, greatly developed jaws, widely opened nostrils, and were of unbridled passions. Prof. Broca found the human thigh bones in their width approaching those of the highest apes, and a remarkable transverse flattening of the tibia; the ascending branch of the lower jaw was very wide, and the cranial capacity equal to that of high races of the present day. In reply to M. Broca, M. Quatrefages cautions anthropologists against too hastily giving undue significance to assumed agreements between fossil man and apes, from any preconceived views of the origin and descent of the human race.—The neolithic or polished-stone age was separated by a considerable interval of time from the old stone age. Many thousand polished-stone implements are collected in the museums of northern Europe and America; they are not found in the river-drift gravels, and are especially abundant in Denmark and Sweden, while the ruder implements of the palæolithic age are unknown there, indicating that these northern countries were not inhabited during the earlier period. No bones of the reindeer nor of the great extinct mammals are found with the polished implements, and nothing made of metals; arrow heads and rough chisels would continue to be made in this, and even in the next and the present ages, while the metals were rare and costly. The Danish shell mounds are the refuse heaps of the people around their dwellings or temporary stopping places; they contain no remains of reindeer, but bones of the domestic animals, and all kinds of household objects lost or bro-

ken, including rude pottery made by hand. Similar shell heaps have been found in the United States, especially along the seacoast, marking the former dwelling places of the aborigines of this continent; several of these have been described by Prof. J. Wyman in vols. i. and ii. of the "American Naturalist" (1868). They are found from Maine to Florida, and are made up of the shells of the mollusks used by them as food, especially the clam and quahog, with bones of the elk, deer, beaver, bear, dog, various fur-bearing mammals, birds, and especially the great auk, now believed to be extinct; occasional pieces of charcoal, and implements of bone and stone, but no human remains, are found. The growth upon them of large trees proves that they must be several centuries old, though not so ancient as the shell heaps of Denmark; they show a great variety of animal food, to say nothing of the vegetable; they afford no trace of any intercourse with European nations. The layers are from $\frac{1}{2}$ to 3 feet thick, and sometimes 250 feet long and 40 or 50 wide, and near the seashore, which has evidently been raised since their deposition; there are sometimes several layers, separated by earth, indicating successive occupations. Some of the lake dwellings of Switzerland (see LAKE DWELLINGS) belong to this age, while those yielding metal implements belong to the next or bronze age. There are evidently two classes of these lake dwellings. Many burial mounds contain flint daggers and stone implements, and none of metal. Bodies in the stone age were either buried in the sitting posture or were burned; they were rarely, if ever, extended at length. Bones of the dog in the shell heaps, and of the ox, sheep, goat, and pig in the lake villages, lead to the belief that these animals were then domesticated; the domestic fowl and the cat were unknown. The hunting had by this time given place to the agricultural state, as we find corn-crushers, blackened wheat, barley, and flax in the lake dwellings, but no oats, rye, nor hemp; tissues of woven flax are met with. Even at this early period two kinds of skulls are found, one long and the other round, indicating the existence of at last two human races, the first perhaps belonging to men of the stone age, and the last to the bronze period, which was now coming on. In the villages of the Swiss lakes the houses were built on wooden platforms extending over the water, resting on piles driven into the mud. Similar villages have been found in Italy, Savoy, the French Jura, Germany, Scotland, and Wales; and from their number and size they must have been the centres of a numerous population, a single one having had more than 40,000 piles. Some of the people on the coast of Borneo and in parts of Polynesia make their huts on similar platforms at the present day. The charred posts and grains indicate that these villages were destroyed by fire.—In the succeeding or bronze age, implements and arms of this alloy were extensively

used, and many are preserved in collections; stone implements and arrow heads are found with the bronze, showing that the former serviceable material was still used. The later Swiss villages and many tumuli or mounds belong to this period. Bones of the domestic animals and cultivated plants are found instead of wild ones; the piles of the villages are cut squarely with metal, and not irregularly by stone or charred by fire; the pottery shows marks of the wheel; gold, amber, and glass were used for ornamental purposes, though silver, lead, zinc, and iron appear to have been unknown; there were no coins in use, and there are no signs of writing or inscriptions; skins were worn, though tissues of flax and wool were also used; the ornamentation is geometrical, consisting of lines, circles, zigzags, and triangles, much as is now seen on the mats made by the tribes of central Africa; the handles of the arms and bracelets indicate a small race. The use of bronze proves commerce, and the tin must have been brought from Cornwall, and copper must have been used before bronze. As copper implements are not found in western Europe, it is probable that the knowledge of bronze was introduced into and not discovered in Europe; it could not have been introduced from Italy, as the Romans never entered Denmark, and such implements have rarely been found in Italy, and none of the peculiar leaf-shaped bronze swords, so common now in the north, are seen in southern museums. If such are of Phœnician origin, as Prof. Nilsson maintains, it must have been before their historic period, as they were familiar with iron from the earliest known times.—After a transition period, during which bronze was used with iron, as proved by iron instruments with bronze handles, though never the reverse, we come to the iron age, which leads directly to the historic. In this the weapons and cutting instruments were generally made of iron; such were in use by the Britons at the time of the Roman invasion; coins were employed, and silver was used for ornamentation of the person and of implements; the pottery was much better, and the weapons were more artistically made and ornamented. Neither bronze nor stone weapons were used in northern Europe at the beginning of our era, and the people of the north and west were considerably above the savage state. The resemblance of the rude implements in the old and in the new world, in the same stage of civilization, is very striking.—M. Lartet makes only two prehistoric ages, the stone and the metal. The stone age he divides into—1. that of the extinct mammals, like the mammoth and the cave bear; 2. that of the migrated existing animals, the reindeer epoch; 3. that of the domesticated existing animals, the polished-stone age. The metal age he subdivides into the bronze and the iron ages. According to him, primitive man lived in a comparatively cold, barren, and wet earth, presenting no fruits for

his sustenance, and no opportunity for agriculture; essentially predaceous and carnivorous, an eater of raw flesh, and a cannibal, like many savage races of the present day; with small skull and brain, retreating forehead and prominent jaws, short but robust, below even the New Zealander and Australian of to-day; and paying a great and superstitious respect to the dead. In the reindeer period there was an advance, as shown by the more symmetrical though unpolished weapons, but as yet no agriculture; the great mammals began to disappear, and to be replaced by smaller and more useful forms. The mastodon was evidently known to the founders of the Central American cities, and its figure is pictured on their walls; as the mastodon survived the mammoth, the former came down almost to the historic period. During the reindeer epoch the glaciers again advanced, and the climate became cold, though to a less degree and for a shorter time than before; after this came another warmer period, when the glaciers melted, causing the floods which as deluges enter into the traditions of so many nations; then the great mammals were exterminated, and the reindeer and the arctic animals retreated to the north, where they have since remained. In the next epoch, with a continued mild climate, man became agricultural, had polished implements, and made the dog his companion. In the bronze age man made still greater advances, domesticating animals, cultivating grains and fruits, and smelting metals, especially copper. The iron age insensibly merges into the historic period. The mound-builders M. Lartet considers intermediate in civilization between the polished-stone and the bronze epochs of Europe, not in time, but in stage of advancement; they lived in towns, and were not only hunters, but miners, potters, weavers, agricultural, artistic, and commercial. The stone, bronze, and iron ages do not indicate definite periods of time in man's civilization; every race goes through these ages, some more rapidly than others. Some eastern nations had probably passed out of their stone age at least 3,000 years B. C.; some in northern and central Europe were in this age when Cæsar subjugated Gaul; the Sandwich islanders were in their stone age in the time of Capt. Cook; the Esquimaux and the North American Indians generally are now in their stone age; it is simply the age of the infancy of the race. In America the copper preceded the bronze age; the latter existed when the Spaniards first visited Mexico and Peru. The mound-builders of the Mississippi valley used implements of pure copper, hammered cold, obtained from the region of Lake Superior; they preceded the Aztecs. Judging from the forests overlying this old civilization, the copper age must have been at least 1,000 years ago. Africa had no bronze age, passing from the stone to the iron age, on account of the exceptional occurrence of iron there, which the natives work skilfully both

cold and hot. The men of the iron age in Europe were probably the Celts, conquered and described by the Romans. The Esquimaux, the Australian, and the North American Indian will probably never pass beyond the stone age, and will finally become extinct, the first from climate, and the last two from contact with superior races with which they cannot compete. It is most likely that the savage Ligurians and Iberians described by Cæsar as living in caves, and conquered by him, were the southern representatives of the old stone age, while the Finns and Lapps are the more modern and northern remains of the later stone age. The American Indians, the shepherds of Tartary, and the African races have no written history of their own; this has been attained only in comparatively recent times even by the civilized nations of Europe. From geographical causes the Tartars have always been migrating shepherds, occasionally uniting in formidable hosts, the scourges of more civilized races, as when eastern Europe was overrun by the hordes of Genghis Khan and Tamerlane.—For full information on the subject of archæology, the reader is referred to the writings of Christy, Lartet, Boucher de Perthes, and Quatrefages in France; Schaffhausen, Virchow, and Lindenschmit in Germany; Thomsen, Engelhardt, Steenstrup, and Nilsson in Denmark; Troyon, Keller, Morlot, Vogt, and Desor in Switzerland; Gastaldi, Canestrini, and Forci in Italy; Schoolecraft, Squier, Foster, Davis, Whittlesey, and Wyman in the United States; Crawford, Prestwich, Boyd Dawkins, in England, and especially to Lyell's "Antiquity of Man," and Lubbock's "Prehistoric Times." For details on the stone age, see "Primitive Inhabitants of Scandinavia," by Sven Nilsson (London, 1868).

ARCHLEOPTERYX (Gr. ἀρχαῖος, ancient, and πτέρυξ, wing), the name given by Owen to the recently discovered long-tailed or reptilian bird

along each side, the feathers being in pairs corresponding to the number of vertebrae, and diverging at an angle of 45°; the last pair extended backward nearly in the axis of the tail, and 3½ inches beyond it. The wing appears to have had a two-jointed finger, and its breadth was made by feathers as in birds, and not by an expanded membrane as in the pterodactyl and other flying reptiles; the feet were also like those of birds, and its body was covered with feathers. As we know comparatively little of the terrestrial reptiles of the triassic or preceding period of the mesozoic age, and very little of its bird-like forms beyond that afforded by the footprints in the Connecticut valley, it is expected by naturalists friendly to the doctrine of evolution that future researches will reveal birds more reptilian than the archæopteryx, and bird-like reptiles, which will go far toward filling the gap which now exists between reptiles and birds.

ARCHANGEL (Russ. *Arkhangelsk*). I. The northernmost government of European Russia, bounded N. by the White and Polar seas, E. by the Ural mountains, and S. and W. by Vologda, Olonetz, and Finland. It includes the islands of Nova Zembla, Vaygatch, Dolgoi, and Kolguyev, and has a continental area of about 290,000 sq. m., and an estimated total area of about 340,000 sq. m.; pop. in 1867, 275,779. It is watered by the Petchora, Mezen, Dwina, and Onega, all of which flow north. Lapps, Finns, and Samoyeds, many of them still heathen, form the native population, living independently among the conquering Russian settlers. The country is covered with immense forests. The soil yields vegetables, oats, barley, hemp, and flax. The principal towns besides the capital are Kola, Kem, Onega, Pinega, and Mezen.

II. The capital of the preceding government, named after a monastery dedicated to the archangel Michael built there in 1584, situated on the river Dwina, 30 m. from its mouth in the White sea, 450 m. N. E. of St. Petersburg, in lat. 64° 32' N., lon. 40° 33' E.; pop. in 1867, 20,178. It has a military and a civil governor, an archbishop, a high school or gymnasium, a navy yard, and several private ship yards. For nearly a century and a half, previous to the construction of St. Petersburg, Archangel was the principal and indeed the only mart of the Russian import and export trade. As early as the time of Queen Elizabeth English merchant ships occasionally entered the mouth of the Dwina, and they were soon followed by those of the Dutch and the German Hansa. The harbor is large and one of the best in northern Europe, though somewhat obstructed by a sand bank at the entrance. Archangel is still one of the principal points for the trade with the interior of Russia and with Siberia, the Dwina being connected by canals with the Volga, and thus with Moscow and Astrakhan. The ice disappears in April, and the navigation closes in September. The principal objects of trade are fish, fish oil, tallow, linseed, furs,

Archæopteryx, Restored.

of Solenhofen, one of the connecting links between the reptile and the bird, which made its appearance, as far as known, during the oolitic epoch of the jurassic period. In the mesozoic age, not only the mammals but the birds had reptilian characters, and the earliest birds had long vertebrated tails. The tail in *A. maerurus* (Owen) was 11 inches long and 3½ wide; it consisted of 20 vertebrae, with a row of feathers

hides, lumber, wax, iron, linen, bristles, and caviare. In 1855 the harbor of Archangel, defended by a fort, resisted the English attacks. Archangel, being able to receive the largest men-of-war, soon afterward became one of the chief places for the construction and maintenance of the Russian navy. The buildings of the admiralty or navy board, as well as the barracks for sailors, are situated on the island of Solombalsk. In summer Archangel sends out numerous fishing boats, and in winter hunters to the utmost northern regions, such as Spitzbergen, Nova Zembla, and the mouth of the Lena in Siberia. A special company has been formed in Archangel for the herring fishery. In 1868 the exports to Great Britain, consisting chiefly of linen goods (305,890 pieces) and oats (8,728,244 bushels), were valued at £960,938, and the total exports at £1,504,211.

ARCHBISHOP (Lat. *archiepiscopus*), the chief of the bishops of an ecclesiastical province. The first formal sanction of this authority was by the council of Nice, in 325, which distinguished the bishops of the capitals as metropolitans, and the more eminent of the metropolitans were termed archbishops or patriarchs. In the 8th century the title was applied to every metropolitan and to the more eminent of the bishops. Since that time, in Roman Catholic countries, the archbishops have had a more definite position in the hierarchical scale, ranking next below patriarchs, although their prerogatives have considerably varied. They possess a double character, exercising over their own diocese ordinary episcopal functions, and also having a limited jurisdiction over the bishops of their province, who are termed suffragans. They claim the right of calling provincial synods, of presiding at them, and publishing their acts; also the right of supervision; and an appeal lies to them from the decisions of the bishops. The archbishop also supplies benefices left vacant by the bishops for a longer time than that prescribed by the canons, and receives the bulls of the pope, which he announces to his suffragans. The symbol of his superior authority is the pallium, a band of white woolen worn around the shoulders.—The archiepiscopal dignity has been retained in the Greek and Anglican churches. The ecclesiastical government of England is divided into two provinces, Canterbury and York. The archbishop of Canterbury is the chief primate and metropolitan of all England, first peer of the realm, and member of the privy council. It is his prerogative to crown the king, and he is consulted by the ministry in all ecclesiastical affairs, and generally delivers in parliament the sentiments of the bench of bishops. The archbishop of York crowns the queen, and is her chaplain. He also belongs to the privy council, but his inferiority to the archbishop of Canterbury is recognized in his being styled simply primate of England, while the latter is styled primate of all England. The two archbishops have precedence of all temporal peers except-

ing those of the blood royal, and excepting the lord chancellor, who in processions is interposed between them. The archbishop of St. Andrews was the metropolitan of Scotland while episcopacy prevailed in that country, and the archbishop of Armagh is primate of all Ireland.—In Denmark the bishop of Copenhagen has precedence of the others, but the bishop of Seeland is the metropolitan, and anoints the king. In Sweden the bishop of Upsal is the sole archbishop. In Germany, three of the archbishops, those of Treves, Cologne, and Mentz, were electors of the empire.

ARCHDEACON (Gr. *ἀρχιδιάκονος*, chief minister), an ecclesiastical dignitary, the assistant of the bishop. At the beginning of the 4th century there was in almost every diocese an archdeacon, invested with authority by the bishop, particularly in the administration of temporal affairs. To him belonged the care of preserving public order and propriety during the divine service, of guarding the ornaments of the church, and of tending the poor throughout the diocese. He was called the hand and the eye of the bishop, and, from his influential position, became recognized as superior to the priesthood, though retaining only the deacon's consecration. As overseer of the deacons and of the younger clergy who were not yet consecrated, he had the supervision of their education and studies, so that a certificate from him was required before their ordination to the priesthood. When the dioceses began to enlarge, and the metropolitan churches to attach to themselves the neighboring country congregations, it became necessary to divide the diocese into a number of archdeaconries. The archdeacons increased in independence and power till the 13th century, when they claimed a jurisdiction proper to themselves, and the right to appoint their own subordinates. Several synods sought directly to limit their prerogatives, and it was finally decreed by the council of Trent that henceforth the archdeacons should hold their right of supervision only by the bishops' permission. From that time they have gradually disappeared from many dioceses. England is divided into 67 archdeaconries, and it is imperative upon each archdeacon to visit his district at least once in three years. It belongs to him to see that the churches and chancels are in repair, that everything is done conformably to the canons, and to hear from the churchwardens any representations of public scandal. The archdeacons are appointed by their respective bishops.

ARCHDUKE (Ger. *Erzherzog*), a German title in use from very early times. We find among the Franks archdukes of Austrasia. The title also existed in Lorraine and Brabant, and was especially assumed by the house of Austria, though there is no positive historical record as to when or why it was granted to them by the emperors. The Kahleberg branch of the house of Austria or Hapsburg has used the title since 1156, but without special privileges.

It became hereditary in that line after the promulgation of the golden bull, but the electors did not recognize its validity till 1453. It is supposed, however, that Maximilian I. extended this dignity to his branch of the family, attaching to it various privileges, and placing the archdukes in every respect above all other crowned vassals of the German empire. The Hapsburgs have preserved it ever since; and since the assumption by the emperor Francis of the title of emperor of Austria (1804), all the male and female members of that house have been called archdukes or archduchesses.

ARCHELAUS. I. Surnamed Physicus, or the Naturalist, a Greek philosopher, supposed by some to have been a native of Athens, by others of Miletus. He flourished about the middle of the 5th century B. C., and was a pupil of Anaxagoras. Archelaus is said to have been the first philosopher who taught physics in combination with ethics, at least in Greece. He held that the antagonism of heat and cold caused the separation of fire and water, and produced a slimy mass of earth; that the action of heat upon the moisture of this mixture generated animals, originally nourished by their native mud, and gradually becoming capable of propagating their species; that these animals were all endowed in different degrees with intellect; and that man, separating in time from his brother animals, rose to his superior condition. He held also the doctrine that "right and wrong are not from nature, but from custom." After the banishment of Anaxagoras from Athens, Archelaus established himself in that city, and is said to have instructed Euripides and Socrates. **II.** A king of Macedon, from 413 to 399 B. C. He was, according to Plato, an illegitimate son of Perdiccas II., and a monster of cruelty. If we may believe Thucydides, however, Archelaus, by erecting fortresses, forming roads, and adding to his military strength, established the basis on which Philip and Alexander raised the superstructure of Macedonian power. He instituted public games at *Ægæ*, or at *Diium*, which he dedicated to the muses and Zeus. He was a lover of literature, science, and the fine arts. His palace was adorned with paintings by the greatest Grecian masters, and was the resort of Euripides, Agathon, and other distinguished men. Archelaus is said to have been slain at a hunting party by his favorite Craterus, but whether accidentally or deliberately is not known. **III.** The greatest of the generals of Mithridates the Great of Pontus, born in Cappadocia. He commanded the army which his master sent against Nicomedes, king of Bithynia, whom he encountered in Paphlagonia, and completely defeated. On the outbreak of the terrible struggle known in Roman history as the first Mithridatic war, he was sent with a naval and military force into Greece. He subdued many of the *Ægean* islands and compelled the Athenians to take part against the Romans; but when Sylla became his opponent

his triumphant career terminated. At *Chæroneia* and *Orchomenus*, in *Beotia*, his Asiatic myriads were overthrown and almost annihilated (86 B. C.), and he was himself driven to flight and concealment. Mithridates now commissioned Archelaus to negotiate with his conqueror. The two generals met at *Delium*, where Sylla is said to have vainly endeavored to induce Archelaus to betray his sovereign. Afterward a preliminary treaty was concluded, which was not approved by Mithridates; but Sylla by the advice of Archelaus had an interview with the king at *Dardanus* (84), and there made with him a treaty so favorable to the Romans, that henceforward Archelaus, the principal mediator in the matter, was regarded as a traitor, and had ultimately to take refuge with his former antagonists from the vengeance of his king. **IV.** Son of the preceding, was made by Pompey in 63 B. C. priest of the goddess of war at *Comana* in *Cappadocia*. This office conferred on him the power of king over *Comana* and its territory. When *Berenice*, queen of *Egypt*, proclaimed that she was desirous of marrying a prince of royal blood, he pretended to be the son of Mithridates, won her hand, and presently found himself king of *Egypt*. *Gabinus*, the proconsul of *Syria*, having espoused the cause of *Ptolemy*, marched an army into *Egypt*, where a battle was fought in which Archelaus lost his crown and his life after a reign of six months. **V.** Son of the preceding, succeeded to the office of his father at *Comana*. In 51 B. C., having aided the insurgents in *Cappadocia*, he was expelled from his dominions by *Cicero*, then proconsul of *Cilicia*. After the *Alexandrian* war he was deprived of his office by *Julius Cæsar*, who gave it to one of his own adherents. **VI.** Son of the preceding, was made king of *Cappadocia* by *Mark Antony*, in 36 B. C. *Augustus* confirmed him in the possession of his kingdom, and even added to it a portion of *Cilicia* and *Lesser Armenia*. Archelaus was once accused at *Rome* by his own subjects, but he had *Tiberius* for an advocate on the occasion, and was acquitted. But afterward, while sojourning in *Rome*, Archelaus was so impolitic as to offend *Tiberius*, and when the latter became emperor he invited the king to visit *Rome* once more, and, as soon as he came, had him accused before the senate of meditating treason. His old age saved his life, but he was compelled to remain in *Rome*, where he died soon after (A. D. 17). On his death *Cappadocia* was converted into a Roman province. **VII.** A son of *Herod the Great*, was proclaimed king by the army on the death of his father (4 B. C.). Shortly after his accession a sedition broke out, in the suppression of which he manifested the cruelty of his nature. He then went to *Rome* to solicit from the emperor the confirmation of his title, which was disputed by his brother *Antipas*. Dividing the kingdom between them, *Augustus* gave Archelaus the sovereignty of *Judea*, *Samaria*, and *Idumea*,

with the title of ethnarch. On his return from Rome he transgressed the Mosaic law by taking to wife Glaphyra, the not childless widow of his brother Alexander. In the 10th year of his reign he was accused by the Jews before Augustus of various crimes, and being found guilty, was deprived of his dominions, and banished to Gaul (A. D. 8), where he died. **VIII.** A sculptor, a native of Priene, and the son of Apollonius. He is supposed to have lived in the reign of Claudius. He made the marble bass-relief representing the apotheosis of Homer. This work is now in the British museum.

ARCHENHOLZ, Johann Wilhelm, baron, a German author, born at Langenfurt, a suburb of Dantzic, Sept. 3, 1745, died near Hamburg, Feb. 28, 1812. He served in the Prussian army from 1760 to 1763, and afterward spent 16 years travelling over Europe. On his return to Germany he devoted himself to literary pursuits, and lived successively at Dresden, Leipsic, Berlin, and finally at Hamburg. His work on "England and Italy," and his histories of Queen Elizabeth and Gustavus Vasa, enjoyed popularity; but his most valuable work is that on the seven years' war. His "Annals of British History since 1788" are piquant and full of anecdote. In his "Historical Essays" he gives an account of the filibusters and pirates who infested the West Indies during the 17th century. From 1782 to 1791 he edited a periodical called *Literatur und Völkerkunde*, and from 1792 to the time of his death he was editor of the *Minerva*.

ARCHER, an unorganized county in N. W. Texas, near the Indian territory, watered by branches of the Wichita river; area, 900 sq. m. This county was returned as having no population in 1870, its settlement having been delayed by Indian depredations. It has but little good farming land, but is well adapted to stock raising, having fine grass in abundance and plenty of water. The county is regarded as one of the most valuable in the state for its minerals, among which is bismuth.

ARCHERY, the art of shooting with the bow, which is probably the oldest weapon for use in other than hand-to-hand combats, and the

earliest implement of the chase. The mention of the bow in the oldest portions of the Hebrew Scriptures, and its constant appearance in the sculptures of Nineveh and of Egypt, show that it was used by the oriental nations from the earliest times; and these nations long preserved their superiority in its use; for the Greeks and Romans, who themselves made little use of the bow, though they employed foreign archers as mercenaries, found in their wars with eastern races that bowmen formed the chief strength of their enemies. The Cretans, however, excelled in the use of that weapon. The Persians, Parthians, and Numidians were among the best archers of antiquity of whom we have authentic record. In India and China the bow was also the chief weapon; and it was probably of the same form as those

Chinese Bow and Ornamented Quiver.

Bow and Arrows used in India.

now known in these countries, though seldom used.—But the great period of archery began with the Norman conquest of England, when the longbow, originally a weapon of the Norse tribes, and brought into western Europe by Duke Rollo, was used with such effect by the Normans that the Saxons found no weapon to successfully oppose it. Upon the amalgamation of the two peoples into one nation, it became the English national weapon, and was rapidly made famous. The proper length of the longbow was the height of the archer using it. The arrow was half as long as the bow; from 60 to 90 lbs. was the force needed to draw a fitting arrow to the head on a bow six feet long. Such an arrow was called "a cloth-yard shaft," from the measure, a cloth yard or three feet. The longbow was made of Spanish yew, English yew, or ash—mentioned in the order of their excellence for the purpose. Arrows were made of ash, oak, and yew, weighed from 20 to 24 pennyweights, were tipped with steel and feathered with goose feathers. The bowstrings were of plaited

English Longbow.

silk. The power of flight, correctness of aim, and penetration of these terrible missiles were prodigious. In shooting matches, 300 yards was the common range, and the ordinary mark was a straight willow or hazel rod, as thick as a man's thumb and five feet long; and such a mark a good archer held it a shame to miss. At 200 yards no armor but the best Spanish or Milan steel plate could resist the English arrow; and the legends of men and horses shot through and through are proved by corslets of the stoutest plate, preserved in several collections, where the shafts have been driven through the breastplate and the whole body of the wearer, and then through the steel backplate, not inferior in strength to the breastplate. In shooting, the longbow was held perpendicularly at arm's length, and the bowstring drawn back until the arrow feathers were opposite the right ear.—While the English archers were the best in the world, and their longbow was the most formidable weapon, several nations of continental Europe acquired great dexterity in the use of the crossbow

famous crossbowmen, and several provinces of France furnished good archers.—Archery disappeared as firearms came into use; and as an instrument of war and the chase, the bow is now confined to the most savage tribes. Many of the North American Indians were expert with the bow; but they early adopted the musket or the rifle, and now, except among the most remote frontier tribes, the bow

Crossbow.

arbalast. This consisted of a bow fixed transversely at the end of a wooden stock somewhat resembling a modern gun stock; along the top of the stock ran a barrel slit nearly to the muzzle, in such a manner that the string of the bow could pass through the slit and be drawn along it until caught by a trigger; this latter being pressed, the string was released, and swept forward with great force along the slit barrel, discharging the bolt or arrow which had been placed in it. Sometimes the arrow was placed in a simple groove in the top of the stock, along which the released string swept. This bow was generally of steel, and so strong that a steel winch was often fixed to the stock for the purpose of drawing back the cord. In shooting, the crossbow was aimed from the shoulder, like a musket. The Genoese were

African Bow.

is never seen unless in the hands of children or as an implement for catching fish. The Comanches, however, are an exception, for to this day their force consists in their skillful archery. Their bows are short, and their arrows clumsily pointed; but they are properly feathered, and the warriors discharge them with such force that they have been known to pass entirely through the body of a bison. Among many of the African tribes, too, the bow is still in use.

ARCHES, Court of, one of the ten English ecclesiastical courts, so called because its sittings were formerly held in the church of St. Mary-le-Bow (*Sancta Maria de Arcubus*) in London, whence they were in 1567 transferred to the hall of the doctors' commons. This court has original jurisdiction in most ecclesiastical causes arising in 13 parishes in London, which form a deanery. The presiding officer, called the dean of the arches, is also the deputy of the archbishop of Canterbury, so that the court of arches has an appellate jurisdiction in all ecclesiastical causes arising out of the diocese of York. Formerly the jurisdiction of this court was very extensive, especially in matrimonial and testamentary matters; but these have within a few years been transferred from the ecclesiastical courts to the crown, and divorces to the divorce court. The practitioners in the ecclesiastical court are styled doctors, advocates, and proctors, and must before admission to practice obtain the fiat of the archbishop, and then be duly admitted by the dean of the arches. This court has now but little business to do; but the dean, as president of the college of doctors of law, is usually constituted principal judge in admiralty.

ARCHIAS, Anus Licinius, a Greek poet, born at Antioch toward the close of the 2d century B. C., and well known to us only through the oration of Cicero in his defence. When a young man he went to Rome, and was treated with much attention by the leading men of the republic, and especially by the Licinian family, whose name he assumed as a token of respect. He attended Licinius Lucullus, the praetor, to Sicily, and afterward to Heraclea in Lucania, whither his patron was banished for his conduct in the servile war. He was with the younger Lucullus in Asia during the first and third Mithridatic wars, and in the interim he accompanied him into Africa. He at length returned to Rome, where an accusation was brought against him for having assumed without just title the privileges of a Roman citizen. The case was tried before Q. Cicero, who was then praetor, and whose relative, Marcus Tullius, undertook the defence. The result is unknown. Cicero and Quintilian assert that the poems of Archias were equally remarkable for beauty of style and variety of thought. They are all lost, except some epigrams preserved in the Greek Anthology, if indeed these be justly attributed to him.

ARCHIATER (Gr. *ἀρχίατρος*, chief physician), a title which seems in the first place to have been purely honorary and not official. In the times of the Roman emperors Greek physicians were encouraged to come to Rome and enter the imperial service; and it was to one of these, Andromachus the elder, that the title archiater was first given by Nero. What was intended only as a personal compliment to Andromachus passed rapidly into an institution, and archiater became a designation of a class. The archiatri were divided into two classes, the city archiatri and the court archiatri. Later it came to be a civil requirement (under Antoninus Pius) that small cities should have five archiatri, large ones seven, and the largest ten. The archiatri were salaried officers, and were expected to treat the poor gratuitously. As perquisites, they charged the rich for practice, and also had certain stipends called *annuaria commoda*. It was also considered a part of their duty to teach medical science, and to exercise a general supervision over the health of their medical dioceses and the practice of the inferior physicians. The archiatri were usually elected by the suffrages of physicians. In Sweden and Denmark the order still exists.

ARCHIBALD, Adams G., a British colonial statesman, born at Truro, Nova Scotia, May 18, 1814. He studied law in Halifax, was called to the bar in 1839, was elected a member of the legislature of Nova Scotia for the county of Colchester in 1851, and was re-elected in 1855. Next year he became solicitor general in the government of Mr. Young, then a leader of the liberal party, and was re-elected to the legislature by acclamation. Mr. Archibald had a large share in breaking up the mining monopoly which, under a grant

of George III. to the duke of York, held all the coal and other mines of Nova Scotia, under the name of the general mining company. In 1863 he carried a bill through the legislature of Nova Scotia which substituted for the universal suffrage a somewhat restricted franchise. He was one of the delegates to the intercolonial convention held at Quebec in 1864; and his advocacy of that scheme of union cost him his seat when he next appeared for reelection. In the cabinet of Sir John Young, which was formed in 1867, he was president of the council and secretary of state for the provinces, and in 1871 he was appointed lieutenant governor of Manitoba. This office he resigned in the beginning of 1872.

ARCHIDAMUS, the name of five kings of Sparta, of the Proclid or Eurypontid line. The first of the name, son of Anaxidamus, lived during the war with Tegea, about 668 B. C. The second, son of Zeuxidamus, reigned 469-427 B. C. In 464 occurred the terrible earthquake which almost destroyed Sparta, when Archidamus by his energy probably saved the surviving citizens from massacre by the helots. He commanded in the wars against the revolted Messenians. In the discussions at Sparta and Corinth prior to the rupture with Athens he was prominent as an advocate of peace and moderation. In the Peloponnesian war he commanded three expeditions against Attica and one against Plataea. His grandson Archidamus III., son of Agesi-laus II., reigned 361-338 B. C. In 367 he had defeated the Arcadians and Argives in the "tearless battle," so called by the Spartans because they did not lose a man; and in 362 he had successfully defended Sparta against Epaminondas. In the sacred war he aided the Phocians against the Macedonians with money and men, but toward its close he retired on the approach of Philip, leaving the Phocians to their fate. He was killed in Italy, in a battle fought in aid of the Tarentines, on the day of the battle of Cheronæa. **ARCHIDAMUS IV.**, his grandson, and son of Endamidas I., is only known from his defeat by Demetrius Poli-orcetes in 296 B. C. **ARCHIDAMUS V.**, last of the Proclid line, son of Endamidas II., possessed himself of the throne in 240 B. C., but was soon slain by the murderers of his brother and predecessor Agis IV.

ARCHIL, or **Orchil** (Span. *orchilla*; Fr. *orseille*). The red, violet, and blue colors which are known in commerce under the names of archil, cudbear, and litmus are supplied by different species of lichens, *rocella*, *variolaria*, *lecanora*. The *rocella* tribe grow upon rocks on the seacoast in the Canary islands, Sardinia, and Corsica, at the Cape of Good Hope, and on the W. coast of South America. Archil is prepared by digesting the lichens in a hot solution of ammonia, allowing it to stand for a few hours, and exposing the clear solution, which is drawn off from the lichen, in deep jars, to the air for about three weeks; the solution

when concentrated by evaporation forms the archil liquor of commerce. The dye is also met with as a violet paste, and when dissolved in alcohol is used to color spirit thermometers. In consequence of its want of permanence, archil is rarely employed with any other view than to modify, heighten, and give lustre to other colors.—Some confusion exists in reference to the trade names of the different dyes prepared from lichens, but the best authorities confine the use of the word archil to the liquid or pasty dye obtained from the *rocella* tribe. Cudbear is the equivalent of *persia*, and is chiefly made from the *lecanora tartarea*, while litmus is derived from the *rocella tinctoria*.

ARCHILOCHUS OF PAROS, one of the earliest Ionic poets, and the first who wrote in the iambic measure, flourished 714–676 B. C. His father was of noble descent; his mother was a slave. After he had acquired fame by a hymn to Ceres, he became suitor to the daughter of Lycambes, a noble of Paros, who was promised him in marriage, but her father afterward revoked the promise. The poet thereupon composed a lampoon upon the family so bitter that it is said the daughters of Lycambes committed suicide. He subsequently emigrated to Naxos, where he wrote fierce diatribes against his native land. He was no better satisfied with the country of his adoption. In a battle with the Thracians he flung away his shield; for this he endeavored to justify himself by writing a poem in which he said it was better that one should throw away his arms than lose his life. He acquired a high reputation, but his poems were so unbridled that they were prohibited in Sparta. He led a wandering life for years, his journeys extending as far as Italy. Returning to Paros, he was killed in a battle between the Parians and Naxians. The Delphian oracle, which had before his birth promised to his father an immortal son, pronounced a curse upon the man who killed him, because he had “slain the servant of the muses.” Notwithstanding the license of his satires, he was ranked high by Plato, and Horace mentions him in terms of admiration. The fragments of his poems extant have been collected and edited by Jacobs, Gaisford, Bergk, and better by Liebel, *Archilochi Reliquiæ* (Leipsic, 1812).

ARCHIMANDRITE (Gr. prefix *ἀρχι*, and *μάνδρα*, fold or cloister), a superior or general abbot in the Greek church, exercising supervision over several abbeys and monasteries. In the Greek church the archimandrite is subordinate to the bishop of the diocese, having, however, some episcopal functions in the ceremonial of worship. In Sicily, some abbots of monasteries of the order of St. Basil, founded by the Greek church, are called archimandrites. Abbots of monasteries of the United Greeks, established chiefly in Russian Poland, Galicia, and Hungary, are also called archimandrites.

ARCHIMEDEAN SCREW, an apparatus used for raising water. It consists of a screw blade turned around a solid axis, similar to a winding

staircase, and enclosed in a hollow cylinder. When placed in an inclined position, with the lower end in water, the latter will be caught between the screw blades, and the cylinder being turned in the proper direction, the water will be raised and discharged at the upper end. Our first figure represents such an apparatus, with

FIG. 1.—Archimedean Screw with Spiral Blade.

one half of the enclosing cylinder removed, so as to expose the interior arrangement and form of the screw blade. It is still occasionally used, when water is to be raised to a limited height of 10 to 15 feet or less, and the quantity is so large that a dozen pumps would be required; in this case an Archimedean screw turned by two or three men will economize greatly the labor, as with it each man is able to raise per minute 40 gallons of water 10 feet high, or in general to produce the labor of nearly 4,000 foot pounds per minute. This is a larger amount of work than generally can be done with pumps, in which the friction is always considerable when compared with that of the pivots on which the Archimedean screw turns. If water is to be raised to great heights, however, say 90 or 100 feet, this apparatus is not practicable, and pumps are requisite.—Another form of this apparatus is represented in our second

FIG. 2.—Tubular Archimedean Screw.

figure. It consists of a tube wound spirally around a core, and operates on the same principle as the former; but it has a much smaller capacity, and is therefore seldom used on a large scale for practical purposes.

ARCHIMEDES, the most celebrated mechanician of antiquity, born in Syracuse, Sicily, about 287 B. C., died in 212. He is said to have visited Egypt in early life, and to have in-

vented there several useful hydraulic machines, including the Archimedean screw, which he applied to drainage and irrigation. Vitruvius says that King Hiero, suspecting that a golden crown had been fraudulently alloyed with silver, asked Archimedes to discover if it were so. Going one day into the bath tub, it chanced to be full of water, and he instantly saw that as much water must run over the edge of the tub as was equal to the bulk of his body. Perceiving that this gave him a mode of determining the bulk and specific gravity of the crown, he leaped out of the bath and ran home, crying *Eureka, eureka*, "I have found it, I have found it." This was the origin of his discovery of the important principle that a body plunged in a fluid loses as much of its weight as is equal to the weight of an equal volume of the fluid. In his old age he defended his native Syracuse against the Romans under Marcellus with great mechanical skill, and later historians say that he burned the Roman ships by concentrating upon them the sun's rays from numerous mirrors. His purely mathematical works still extant demonstrate him to have far excelled all those who preceded him. The most celebrated are those on the ratio of the sphere and cylinder, on the ratio of the circumference to a diameter, on spiral lines, and on the parabola. He requested a cylinder and sphere to be placed upon his tombstone, and when Marcellus had stormed Syracuse, and Archimedes had been killed by a Roman soldier, the Roman general conferred upon him an honorable burial, and caused the tombstone to be inscribed as he had desired. Cicero, about 140 years afterward, being appointed quaestor over Sicily, sought and found the tomb of Archimedes, overgrown with weeds and thorns.

ARCHIPELAGO (Gr. prefix *ἀρχι*, main, and *πέλαγος*, sea), originally a specific name applied to the Ægean sea, but now a generic term designating any body of water containing a great number of islands, and applied also to the group of islands itself. **I.** The Grecian archipelago (the Ægean, in the wider sense of the word) is an arm of the Mediterranean sea, extending northward upward of 400 m., with an average breadth of about 200 m. Its geographical position is between lat. 35° and 41° N., and lon. 23° and 28° E. Turkey in Europe forms its northern and northwestern coasts, Asia Minor its eastern, and Greece its western, while its southern limit is marked by the island of Candia or Crete. Within these limits the Ægean forms an extremely irregular outline, having numerous armlets and indentations, among which may be mentioned the gulfs of Nauplia (or of Argolis), Ægina (the Saronic), Voló (the Pagæan), and Salonica (the Thermaic), all on the west. It is studded with a vast number of islands, ranging in size from mere rocky islets to areas of 4,000 sq. m. (Candia), and mostly composed of calcareous masses, forming high bluffs or mountain clusters, rising abruptly from the sea. Many of the

mountains reach a height of 2,000 feet, while the highest summit, on Negropont or Eubœa, exceeds 5,000 feet. The Ægean islands, exclusive of Eubœa, the largest of all, are divided into three groups, viz.: the northeastern, including the islands of Thasos, Samothrace, Imbros, Lemnos, Tenedos, and Lesbos; the Cyclades, forming a kind of insular continuation of Eubœa and Hellas proper (see CYCLADES); and the Sporades N., E., and W. of the preceding (see SPORADES). Most of the Cyclades and the northern and western Sporades belong to the Greek kingdom, while Turkey possesses the northeastern group and the eastern Sporades. Many of the islands are picturesque in scenery, and all the arable portions are extremely fertile. The principal productions are silk, cotton, honey, wine, figs, raisins, oranges, and other fruits. Coral and sponge are found among the Sporades, while the Cyclades furnish the pure white marble known as the Parian, from Paros, one of the group, where it was first worked. Here also were found (about 1627) the Arundel marbles, or Parian chronicle, so full of historical interest. In the channel of Negropont (the Euripus) the tide frequently runs in a given direction at the rate of 6 to 8 m. an hour, and then suddenly, without any known cause, sets in the opposite direction at nearly the same rate. The climate of the islands is salubrious, the inhabitants are hardy, and the women noted for beauty. The localities of the Ægean are filled with classic and sacred associations. **II.** The second in importance is the Indian archipelago, which includes that extensive insular region of the eastern hemisphere, extending from the S. E. coast of Asia to Australia, embracing the Philippine group, Sumatra, Java, Borneo, Celebes, and the Molucca and Banda Isles, and stretching between lat. 11° S. and 20° N., and lon. 95° and 135° E. This immense area is bounded by the Chinese sea, the Pacific, Australia, and the Indian ocean. The population of the archipelago consists of two distinct races, the Malay and the negro.

ARCHITECTURE (Lat. *architectura*, from Gr. *ἀρχιτέκτων*, a master workman), the art of building. This term embraces every kind of structure except works of defence and ships. The styles of architecture, like other historical monuments, may be divided into two classes, the first comprising the barbarous art of those nations which lie outside the circle of civilization, and the second comprising the historical styles, beginning with the Egyptian, Assyrian, and Greek, and reaching to our own day. The Assyrian and Greek give evidence of having arisen from a system of wooden construction; in the Egyptian the primitive material seems to have been mud or unburnt bricks. In the subsequent use of stone the forms proper to the original materials became as it were fossilized, and continued in use long after their origin and meaning were forgotten. Of the early achievements and of the progressive steps

of the science of architecture there remain but fragments, though sufficient, with the assistance of history, to teach us their antiquity. Throughout the globe we find remains of edifices which proclaim an early possession of certain degrees of architectural knowledge. The most remarkable vestiges of these primitive structures, save the Celtic monuments, were once supposed to be the works of giants or Cyclops like those mentioned in the *Odyssey*. By whom they were erected, however, is unknown, though they have been attributed to the Pelasgians. The walls of the cities and of the sacred enclosures and tombs were composed of blocks of stone of a polygonal form well adjusted. No cement was used, the interstices being filled with small stones. At times they present horizontal layers whose upright joints are variously inclined. Their entrance gates received different forms, the most common being quadrangular, composed of upright jambs, either perpendicular or inclined, supporting a lintel. Others assume the shape of a pointed arch, the jambs gathering to a point at the summit. Examples also present themselves of truncated pointed archways over the lintel, an arch occasionally being constructed to relieve this member of the superincumbent weight. We are led to suppose that within their city walls the habitations were erected without order, a place being reserved in the midst for public assemblies. Little is known of their domestic architecture, as there exist no vestiges of those palaces so highly spoken of by the ancient poets. Perhaps the most interesting of their structures are their circular subterranean chambers styled treasuries; they present vaulted ceilings, although not constructed on the principle of the arch, the vaulted form being obtained by horizontal annular layers, corbelling inward, and the projecting edges of the stones being taken off after the construction was completed. According to Blouet, they served for tombs as well as for treasuries. Internally they were covered with sheets of bronze. At Mycenæ and Tiryns several examples are to be found.—One of the most ancient nations known to us who made any considerable progress in the arts of design is the Babylonian. Their most celebrated monuments were the temple of Belus, the Kasr, the hanging gardens, and the wonderful canals Nahar Malea and Pallacopas. From the dimensions of their ruins can be formed an idea of the colossal size of the structures they composed. The material employed in cementing the burned or sun-dried bricks, upon which hieroglyphics are still to be traced, was the mortar produced by nature from the fountains of naphtha and bitumen at the river Is, near Babylon.—No entire architectural monument has come down to us from Nineveh, the superb capital of the Assyrians; nor from the Phœnicians, whose cities, Tyre, Sidon, and others, were adorned with equal magnificence; nor from the Hebrews, the Syrians, the Philistines, and many other nations. Our want of

knowledge concerning the architecture of these oriental nations is attributable partly to the devastations of war and partly to the perishability of the materials that were employed, such as gypsum, alabaster, wood, terra cotta, and brick, with which their ruins abound. From recent discoveries, we have been able to see the great affinity existing between many of the works of these nations and those of Egypt and Greece; in their sculptures and ornaments, for example, and in the coloring of the various parts of their structures, which were without doubt polychromatic.—Of the very ancient Chinese monuments we have no trace, they having been destroyed by Tsin-Chi-Hoang-Ti upon his ascending the throne. Their pagodas are merely imitations of the design of the nomadic tent. The Chinese wall is one of the most stupendous structures of the world. Japan, Siam, and the islands of the Indian ocean abound in ancient ruins once sacred to the divinities of the Buddhist faith. The Hindoos, in their colossal structures, with their endless sculptured panels, their huge figures, and their astounding intricate excavations, evince a perseverance and industry equalled only by the Egyptians. The Hindoo structures are remarkable for their severe and grotesque appearance.—The history of the art in other regions and in its later developments may be most conveniently treated under several divisions. I. EGYPTIAN ARCHITECTURE. The architectural types of all other structures of antiquity sink into insignificance when compared with those of Egypt. The obelisks, pyramids, temples, palaces, tombs, and other structures with which that country abounds, are on a colossal scale, and such as can have been executed only by a people far advanced in architectural art, and profoundly versed in the science of mechanics. These works, like the Hindoo structures, were remarkable for their gigantic proportions and massiveness. Intricate and highly painted relief sculptures or hieroglyphics covered the entire extent of their walls. The earliest works of the Egyptians are their hypogæa or spea, wherein their dead were interred, and which served also as subterranean temples. In these excavations, or caves in the flanks of mountains, square piers were reserved in order to support the superincumbent weight. They were covered internally with hieroglyphics and bass-reliefs, enriched with color. Subsequently temples were constructed in the open air. At Amada exists perhaps the most ancient example of these temples. It is peculiarly interesting to archaeologists, as it forms the connecting link between the superb edifices of the Pharaohs and their prototype, the spea. It also furnishes us with the proto-Doric order, combining square pillars with cylindrical columns. The plan of the temples constructed by the Egyptians is very similar to that of their hypogæa, or caves. They were generally approached by an avenue, on either side of which

was a row of sphinxes, leading to the propylon or gateway, before which stood the obelisks, thus forming an entrance into an open quadrilateral court surrounded by porticos.

Ruins of the Temple of Quorneth at Thebes.

Opposite this entrance was another leading into a spacious hall, whose ceiling was supported by columns. In the rear of this principal hall were one or more smaller ones. The walls, ceilings, and columns were decorated with figures in bass-relief and hieroglyphics richly colored. The colors most generally employed were yellow, red, green, and blue. The palaces were constructed upon a plan very similar to that of the temples. We know little concerning the habitations of the great mass of the nation. According to some, houses were constructed in stories, while others assume that their abodes were mere huts. This people devoted their lives and money to the construction of their tombs. Besides their wonderful cities of the dead, hewn in rocks or imbedded in hills, the Egyptians reared their stupendous pyramids, the most gigantic monuments existing. Their ground plan is perfectly square, the sides presenting nearly equilateral triangles. From the immensity of these constructions, some have suggested the probability of the existence of a natural rock or hill within. Whether or not the outer surface was smooth or graduated with steps, when finished, it is impossible for us to decide. The constructions of the Egyptians are in granite, breccia, sandstone, and brick, which different materials are adjusted with much precision. We cannot but wonder at their monolithic obelisks, especially when we reflect upon the immense distances they were transported. The pyramidal shape pervades most of their works, the walls of their temples inclining inward. The jambs to their entrance gates also were generally inclined. The Egyptians never used columns peripterally even under the dominion of the

Greeks and Romans; when the column was used externally, the space intervening was walled up to a certain height. To these circumstances, together with the fact that their monuments were terraced, can be ascribed their massive and solid appearance. With them, columns were employed to form porticos in their interior courts, and also to support the ceilings. The shafts, of different forms, being conical, or cylindrical, or bulging out at the base, sometimes presented a smooth surface; they were rarely fluted, being generally covered with hieroglyphics. Occasionally they were monoliths, but were generally constructed in layers, and covered with hieroglyphics; a circular plinth formed the base. The capitals resemble the lotus, either spreading out at the top or bound together, assuming the bulbous shape; above is a square tablet forming the abacus. Others, of a later date, present projecting convex lobes; while other capitals are composed of a rectangular block with a head carved on either side, surmounted by a die also carved. Caryatic figures were also employed by the Egyptians, and were generally placed against walls or pillars, thus appearing to support the entablature, composed of a simple architrave and a coved cornice, with a large torus intervening, which descends the angles of the walls. II. GRECIAN ARCHITECTURE. The Pelasgians appear to have been the first people settled in Greece numerous remains of whose structures are still extant. Subsequently, from the knowledge possessed by the indigenous tribes, together with that acquired from the Egyptians and the Asiatic nations, the Greeks extracted and developed a style peculiarly their own, and architectural art passed from the gigantic to the elegant and classic forms. Under the government of Pericles it flourished with meridian splendor, and some of the most superb edifices the world has ever seen were erected during this period. The Grecian monuments belonged to the states, and upon the public works the governments lavished fabulous sums. Heeren informs us that the Greeks placed the necessary appropriation of funds for the public works at the head of the government expenditures. The thoughts of the whole Greek nation, it would seem, were turned toward the adornment of their cities. They forbade by law any architectural display on private residences, and in fact, until after Greece became subject to Macedonia, architects were permitted to work only for the government. The Greeks loved recreation, and the government, as a political necessity, provided the populace with amusements. Hence the Grecian cities were adorned with temples, theatres, odeons, gymnasiums, choragic monuments, and the like.—The Grecian temple consisted of a pronaos or vestibule, and a naos or cella. These sometimes were accompanied by an opisthodomus, supposed to be the treasury, together with a rear portico, or posticum. According

to the disposition of the columnar decoration, they were styled in antis, prostyle, amphiprostyle, peripteral, dipteral, pseudo-peripteral, or pseudo-dipteral. The principal front of those in antis presents columns in the middle, with antæ on either side, supporting the pediment; in the prostyle, the antæ are replaced by columns, the amphiprostyle presents a similar disposition in the rear as well as the front; the peripteral presents columns forming a portico around the cella; when the lateral columns were engaged, instead of isolated, the temple was styled pseudo-peripteral; the dipteral offered a double colonnade around the cella; in the pseudo-dipteral, one of the ranks of columns was engaged in the wall. They are termed tetrastyle, hexastyle, octastyle, according to the number of columns supporting the pediment. The temples were generally covered; those erected in honor of superior deities were hypæthral, or open to the skies. In these latter, the cella was divided longitudinally into three naves by a double row of columns, which supported the roof covering the side aisles. In order to save room, these rows of columns were in two stories, as thereby they were enabled to attain the desired height with columns of a less diameter. The ceilings of the porticos were subdivided in caissons, often-times highly colored, as were likewise many parts of the edifices. The frieze below the ceiling, on the exterior of the cella walls, was often ornamented with bass-reliefs. The walls internally were decorated with paintings, though it is supposed that generally these latter were not executed directly on the walls, but were suspended against them. The pavement of the cella was usually elevated above that of the portico; that of the Parthenon, however, is level throughout. Opposite the entrance door was placed the statue of the deity of the temple, which was often of colossal size, while others were arranged on either side of the cella, or about the principal deity. They were generally in marble or bronze; sometimes, however, they were of ivory and gold. Besides the different statues of their divinities, the cellas contained altars, tripods, thrones, arms, vases, and utensils of different sorts; all of which objects were generally in precious materials, highly wrought. The more important temples were built on sacred ground; within the peribolus or enclosure were sacred groves, grottoes, altars, columns, statues, &c. The entranceway or propylæum, somewhat similar in plan to the pronaos of their temples, was grand and imposing. Little is known of the theatres and odeons, the graded hemicycles of the former, destined for the spectators, being all that now remains of them. These hemicycles were excavated in the side of a hill. Of the choragic monuments, that of Lysicrates at Athens is the finest example; upon a quadrangular basement was placed a cylindrical monument with engaged Corinthian columns supporting an entablature surmounted

by a dome crowned with a beautiful acroteral motive, upon which is supposed to have been placed a tripod. The Grecian agoras, or public places of assembly, were surrounded by porticos decorated with paintings commemorative of glorious achievements. Within the enclosure were temples, altars, and statues dedicated to their heroes. We know little of the architectural arrangement of the gymnasiums, which contained the halls, porticos, and exedras, where the sages taught their different philosophies; or their baths, accompanied by their dependencies, about which were disposed the stadium and courts for various gymnastic exercises. It is likewise difficult to obtain any accurate idea of the architectural disposition of the domestic habitations, as no examples remain. The beauty and grace which pervade all the works of the Greeks, whether monumental, mechanical, or industrial, lead us to suppose that, although imperfect as regards comfort, they must yet have exhibited a certain degree of elegance. A just idea of the mouldings and ornaments, unequalled for their purity and grace, can be obtained only from personal observation. The styles may be classed in systems or orders as the Doric, Ionic, and Corinthian. They also employed, though rarely, caryatides. Innumerable conjectures exist concerning the origin of these different orders. In all probability we are indebted to the Dorians for the invention of the Doric; although Champollion sees in an Egyptian order, which he styles the proto-Doric, the type of the Grecian order of that name. The oldest example extant is at Corinth. To the Ionians, likewise, is attributed the honor of having first employed the Ionic order, no example of which is to be found in Greece prior to the Macedonian conquest. Vitruvius accords to Callimachus the invention of the Corinthian capital, but foliated capitals of much greater antiquity than any discovered in Greece are to be found in Egypt and in Asia Minor. The most perfect Grecian example of this order is employed in the choragic monument of Lysicrates. Little doubt need be entertained as to the Greeks deriving the idea of their caryatic order from the Egyptians, who often employed human figures instead of columns in their structures.—The Doric holds the foremost rank among the Grecian orders, not only on account of its being the most ancient, the most generally employed, and consequently the most perfected, but more especially because of its containing, as it were, the principle of all their architecture, as well as an exact imitation of all the parts employed in their primitive constructions, which were undoubtedly of wood. Thus we see the post represented by the column, the wall plate by the architrave, the extremities of the joists by the triglyphs; the rafters naturally produce the projection which composes the cornice; while the double pitch of the roof gives us necessarily the form of the pediment. This style, typical of majesty and imposing grandeur, was

Tuscan.

Doric.

Ionic.

Corinthian.

Composite.

almost universally employed by the Greeks in the construction of their temples; and certainly monumental art does not furnish us with the equal of a Greek peripteral temple. The Grecian Doric may be divided into three parts: the stylobate, the column, and the entablature. The stylobate is formed by three receding courses, together about equal in height to the inferior diameter of the column, which dimension is generally used as a measure of proportion in describing the orders. On the uppermost course stands the column, from four to six diameters in height, and whose diameter at top is about three fourths of that at base; the shaft, thus assuming a conical shape (which diminution is in a slightly curved line, is styled entasis), generally bears 20 shallow flutes, their sections forming segments of circles, or similar curves which meet and form a sharp anis. At the base these flutes detail on the pavement; they pass through the hypotrachelium, or necking, and terminate beneath the annulets of the capital, either in a straight or curved line. Upon the shaft is placed the capital, nearly one half of a diameter in height, composed of an abacus, or square tablet, about $1\frac{1}{2}$ diameter in width and one fifth in height. This member is supported by the echinus, of about the same height when there is a necking, but occupying a greater proportion when none exists. This echinus or ovolo bears three, four, or five rings at the bottom, where it dies away in the shaft. The axes of the columns were slightly inclined. According to Villeroy, in a rectangular temple, planes passing through the centres of the columns would meet in a straight line; in a point, if the plan of the temple were square; the columns at the angles following in both cases the direction of diagonal lines. This inclination does not commence until the second course, or about one tenth of the height of the column, if monolithic. The first course being an ob-

lique truncated cone, determines the angle of inclination; the remaining courses forming the column are upright truncated cones, perfectly adjusted one to the other. The inclination of each column is proportional to the distance, to the line joining the foci if the monument be rectangular, or to the centre of the plan of the edifice if square. Thus the columns at the angles are the most inclined, those in the middle of the sides the least. The entablature, about two diameters in height, is subdivided into three parts: the architrave, the frieze, and the cornice. The architrave occupies about two fifths of the whole height, being perfectly simple, crowned by the tænia or continuous fillet, one tenth or one twelfth of its entire height; below this fillet, under the triglyphs, there is a regula, of less height, from which depend six cylindrical drops. The face of the architrave is generally in a vertical plane tangent to the base of the columns. The frieze, of about the same height as the architrave, is terminated on top by a projecting fascia, occupying about one seventh part of its whole height, which breaks around the triglyphs, where it is slightly increased in depth. Horizontally, the frieze is subdivided into triglyphs and metopes, which regulate the intercolumniation in the following manner: A triglyph about one half a diameter in width is placed exactly over the middle of each column, and one in the intervening space. They are separated by the metopes, which in width are equal to the entire height of the frieze. This distribution differs, however, at the angles; here the outer edge of the triglyph is in the same perpendicular line with the circumference of the base. Thus the first intercolumniation, counting from the angles, is contracted. The Greeks also gave a greater diameter to the columns at the angles. The triglyph is subdivided into two glyphs, each one fifth of the

whole width (a triangular fluting or channel formed by the intersection of two vertical planes inclined inward from the face of the tablet), of two semiglyphs, and two interglyphs, each one seventh of the entire width. The glyphs detail on tænia. Above they are sometimes square-headed, sometimes curved; the semiglyphs finish with a curve at the top. The surface of the interglyphs is in the same plane with the architrave. The metopes recede from the triglyphs, and were oftentimes decorated with sculpture. The cornice, projecting about its own height, is composed of a corona, about one half of the whole height, crowned by a square fillet supported by a congeries of mouldings, together about one half of the height of the corona, which latter has on the lower edge a sunken face bearing the mutules and guttæ, which form the soffit or plancher of the cornice, inclined up inward at an angle of about 30° . The mutules are placed directly over the triglyphs and metopes, and are exactly equal to the former in width; they are ornamented with three rows of cylindrical drops. The height of the pediment is generally about $1\frac{1}{2}$ diameter. The cornice crowning the inclined sides of the tympanum differs from the horizontal one at its base, inasmuch as the mutules are left out, and another member superimposed, which is either an ovolo with a fillet, or a cymatium, occupying a space equal to about one half of the depth of the cornice with its mutules. The tympanum was often decorated with sculpture. The flank cornice supported antefixæ, an ornament used to cover the ends of the joint tiles of the roof. The antæ or pilasters, nearly equal in diameter to the columns, did not diminish at the top, nor were they fluted like the columns; they generally had a congeries of mouldings at the top and the bottom. The Greeks never employed peripterally any other than the Doric order.—The Ionic, remarkable for its grace and suavity of proportions, holds a middle place between the simple Doric and the rich Corinthian order. According to some, it was originally employed in funereal edifices. At Telmessus, in Lycia, are to be found tombs cut in the rock, which invariably offer examples of this style; moreover, on the Grecian vases the representation of the Ionic column is symbolical of a sepulchral monument. This order, as well as the Corinthian, is more tractable than the Doric. Like the latter, it is composed of stylobate, column, and entablature. The column has a base as well as a capital, and is about nine diameters in height. The base, about one half a diameter in height and $1\frac{1}{2}$ in width, is composed of a torus resting on the stylobate, a scotia, and a second torus, all about equal, and separated from each other by a fillet, one also finishing the apophyge, or escape of the shaft, which diminishes with entasis about one sixth of a diameter, bearing 24 flutes deeper than in the Doric column, and which are separated from each other by fillets. These

flutes finish in the same curve above and below. The capital is about one half of a diameter in height, when unaccompanied by a necking; when one exists, it is about three quarters high. The volutes, carved on the faces of a parallelogrammic block, and connected at the sides by bolsters and in front by flowing lines, are supported by a congeries of mouldings, composed of a bead and ovolo. Superimposed is the abacus. These volutes are a full half diameter in depth, and extend in width about $1\frac{1}{2}$ diameter. When this capital is accompanied by a necking, a torus is introduced in corbel mouldings, supporting the volutes, and the necking itself, ornamented with the honeysuckle and tendrils, is separated from the shaft by a fillet or a bead. The outer volute of the capital at the corners is inclined at an angle of 45° , so as to present a volute when viewed from either side; internally the two volutes meet at right angles. The entablature, a little over two diameters in height, is composed of architrave, frieze, and cornice. The former, occupying about two fifths of the whole height, contains three equal fascias, slightly projecting one beyond the other, the lowest one being in a plane tangent to the inferior circumference of the column. On the upper edge of the architrave are a few corbelling mouldings, comprising a little less than one quarter of its whole height. The frieze is of the same height with the architrave, recedes slightly, and is either plain or ornamented with sculpture. The projection of the cornice is about equal to its height. It is composed of bed mouldings undercutting the corona; this latter is of great breadth, and the crown mouldings are of much less importance than in the Doric. The pediment of this order is also rather lower, and its cornice is crowned by a rectangular fillet surmounting small mouldings. The intercolumniations differ from two to three diameters.—The only example of the Grecian Corinthian is to be found in the choragic monument of Lysicrates, which is a small circular structure decorated with engaged Corinthian columns, placed upon a high rectangular basement. This order is composed of a stylobate, a column, and entablature, the first occupying in height a little more than one diameter. The column is about 10 diameters high, has a base somewhat similar to the Ionic, between one third and one half of a diameter in height, and in width rather more than $1\frac{1}{2}$ diameter. The shaft, whose top diameter is about five sixths of that at the base, bears 24 flutes nearly semi-circular, terminating at the bottom in the same curve, and at the top in leaves, the fillets forming stalks. The capital, separated from the shaft by a groove, is a little more than $1\frac{1}{2}$ diameter in height. Its cylindrical body is surmounted at the bottom by a row of water leaves occupying about one sixth of the entire height. Above them is placed a row of acanthus leaves twice as high as the former, seemingly buttoned

on. Between this second row and the abacus are helices and tendrils, the latter supporting honeysuckles in the middle of the abacus, which member is about one seventh of a diameter in height, and in plan presents a square with concave sides whose angles are cut off at 45° ; its section presenting a fillet, on which reposes a cavetto and an ovolo separated by another fillet. The entablature is about $2\frac{1}{2}$ diameters in height, of which the architrave and cornice occupy separately rather more than one third, and the frieze rather less. The architrave is divided into three equal fascias, inclined inwardly sufficient to bring the outer edges in the same plane with the inferior diameter of the column; these fascias together are crowned by corbelling mouldings, being one sixth of the entire height. The frieze is slightly inclined also and is sculptured. The projection of the cornice is about equal to its height. The bed mouldings have about two fifths of this projection, and occupy five eighths of the entire height of the cornice, undercutting the soffit. Their principal feature is a dentilled member, more than one quarter of the whole cornice in height. The height of the corona is only three eighths of the cornice, and nearly one third of this is taken up by the crowning ovolo and fillet. In this example the cornice is surmounted by a cut fascia supporting antefixæ, somewhat similar to those employed on the flanks of Doric and Ionic temples. The intercolumniation is $2\frac{1}{2}$ diameters. In the example offered us at the Acropolis of Athens the caryatides stand on a stereobatic dado, placed on the stylobate; the antæ bear the mouldings of the temple to which they are attached, forming base mouldings to the dado, which has also a cornice. The entire height of the stereobate is about three fourths of that of the figures, taken together with their base and capital; the former is a square tablet or plinth, the latter a circular moulded block crowned by an abacus. The entablature is about two fifths of the height of the figures, and is nearly equally divided between architrave and cornice. The upper of the three fascias of the architrave is ornamented with circular disks. The cornice is composed as usual of bed mouldings, corona, and crown mouldings, the former with dentilled member forming about two fifths of the whole height. The researches of Mr. Penrose have proved that all the horizontal lines of the Greek temples were curved, and that most of the plane faces inclined either out or in. These refinements were evidently intended in part to counteract certain obvious ocular illusions, but some of them are difficult to account for. Similar refinements are found in mediæval and modern work. III. ETRUSCAN ARCHITECTURE. The polygonal formations observed in the walls of Etruria belong to the Pelasgic civilization, and are similar to those of Greece and of Asia Minor. The commercial relations existing between the Etruscans and the Hellenes of Greece and Magna Græcia account for the existing simi-

itudes in their artistic productions. The ceilings of the hypogæa, hewn so as to represent caissons, tend to corroborate the idea that their earliest structures were of wood, which, with them as with the Greeks, became the archetype of their structures in stone. To the Etruscans the invention of the arch, constructed on its true principles, has been generally attributed, as likewise the composition of an order styled Tuscan, a species of simple Doric, no entire example of which, however, has been bequeathed to us by the ancients. IV. ROMAN ARCHITECTURE. The history of Roman architecture under its kings and at the beginning of the republic is somewhat obscure, as but few of the monuments of that period remain. The Roman kings fortified the city, and erected various palaces, temples, and tombs. It gradually became adorned with colossal works of art, whose grand features, forming such a contrast with the comparative insignificance of its power and condition, would seem to indicate that the future of imperial Rome had been foreshadowed to its people. The early Romans employed Etruscans in their works. After conquering Greece, Rome became enriched with the spoils of Athens and Corinth. The Greek artists sought protection and patronage among their conquerors, and adorned the imperial capital with structures which called forth unbounded praise. The Grecian style was blended with the Etruscan during the more early period of the Roman school. But as the arch, which was the characteristic feature of Roman architecture, revealed its treasures, the Grecian elements were employed only as a system of ornamentation. Thus, oftentimes, the column no longer served as a support, but was merely used to decorate the pier or wall from which the arch sprang. Great discussions have arisen as to who were the inventors of the arch. In Etruria are found many monuments wherein its design exists, and which are of an anterior date to the construction of the *clouca maxima* (wherewith it is fully developed), and even to the foundations of Rome. It is probable that the Romans borrowed it from the Etruscans, who may have followed eastern examples, but that it owed its useful application to Rome. With its introduction came various important modifications in architecture. Arches were substituted for lintels. With the assistance of the arch great spaces could be covered, and the various combinations of vaulted ceilings naturally ensued.—The early Roman structures were of stone. Subsequently the mass of the constructions was of brick, externally decorated with slabs of marble, and similarly decorated internally, together with stucco work. Bricks seem to have been used by the Romans, partly in consequence of the facility offered by this material for the construction of the arch, and partly because they had but little marble. Stone, terra cotta, bricks, and marble were ingeniously put together in various ways. The edifices of the Romans display a taste for the

luxurious and magnificent rather than for the harmonious and beautiful. Their exterior pavements were variously composed of stone, tiles, marble, porphyry, and other durable materials, laid in cement. Internally their floors were similarly laid in mosaic work. This style of work is supposed to have originated among the eastern nations, subsequently being employed by the Egyptians and Greeks. The walls of the Romans were stuccoed and decorated with paintings in the arabesque style, or covered with various marble, alabaster, and jaspers, while their columns also were of granite, marble, and porphyry. This luxury strikes us the more forcibly, as these apartments, so richly adorned and containing various *chefs d'œuvre* of art, were but very imperfectly lighted; in fact, they were sometimes wholly dependent upon lamps. This, too, is one of the great defects in their dwellings, as can be clearly seen at Pompeii. Their houses generally presented an entrance on the street, accompanied by shops if in a principal thoroughfare, leading into an atrium or court, with a compluvium in the middle and porticoes on the sides connecting with the rooms occupied by the servants. This court connected with another in the rear, also surrounded by a portico, which led to the apartments of the master. But nowhere is this taste for richness rather than simplicity more evident than in comparing the details and mouldings of the Greeks and Romans. It is due the latter, however, to make an exception in favor of their Corinthian order, which they employed as universally as did the Greeks the Doric, and to their structures must we turn for many of the finest types of this order. The column, varying in height from $9\frac{1}{2}$ to 10 diameters, is composed of base, shaft, and capital. The base, about one half diameter in height, in some cases consists of two tori and a scotia, with intervening fillets, placed upon a plinth, as in the examples of the temples of Antoninus and Faustina and of Vesta; in the temples of Jupiter Tonans, of Castor and Pollux, and in the portico of the Pantheon, there exists a double scotia. The shaft diminishes with entasis about one eighth of a diameter, and is generally fluted when the material permitted. These flutes were semicircular, separated by fillets one quarter of their width, and 24 in number. At the upper extremity, the fillet above the cavetto supports a small torus, on which rests the capital, about $1\frac{1}{2}$ diameter in height, composed of two rows of eight acanthus or olive leaves. The lower row, about one third taller than the upper one, occupies about one quarter of the whole height of the capital. The leaves of both finish on the hypotrachelium. Above are helices and tendrils trained with foliage, surmounted by an abacus, composed of a cavetto, fillet, and ovolo, forming together one seventh of the entire height, and which in plan presents a square with the corners cut off; the sides being concave segments of circles, in the middle of each of which is placed a flower or rosette. The entablature is about one fifth

of the column in height, three fifths of it being occupied by the architrave, together with the frieze, the former divided into three unequal fascias, generally separated by a bead and a cyma reversa, and crowned by a small congeries of mouldings, the first fascia impending the shaft at top. The frieze is generally enriched with sculpture. The bed mouldings of the cornice, when decorated with modillions, occupy about three fifths of the total height; when no modillions exist, only one half is taken up by them. They generally consist of a bead, a cyma reversa, and a fillet, a vertical member dentilled or not, another bead, and an ovolo, supporting a plain vertical face, one third of bed mouldings in height, which bears the modillions, and is surmounted by a cyma reversa, which breaks around the same. The modillions are horizontal consoles, in width equal to their height, bearing large volutes at the inner end and smaller ones at the outer extremity, joined by a graceful curve, underneath which spreads an acanthus leaf; the space between them is about twice the width of the modillion itself. Resting upon the modillions is the corona, surmounted by a small congeries of mouldings, a cymatium, and a fillet. The soffit of the corona is coffered between the modillions; in the centre of each is placed a rosette.—The composite order may be considered as a sort of Corinthian, as the principal difference exists in the capital, where the volutes occupying about one quarter of the total height rest upon a bead and ovolo; the central tendrils are also omitted, and the upper row of leaves is higher than in the ordinary Corinthian. Besides this particular composite capital, the Roman monuments furnish us with others ornamented with trophies, eagles, masks, &c. The pediments of the Roman edifices were steeper than those of the Grecian; the cymatium was continued along the flank cornices, thereby doing away with the antefixa.—The Doric order, on account of its simplicity, was very rarely employed by the Romans. In the few examples which have been preserved, the proportions are more slender, the projections less hardy than in the Grecian Doric; and, in endeavoring to give it more elegance, this order lost with the Romans its simplicity and grandeur. At Albano an example has been discovered where most of the mouldings are ornamented. The baths of Diocletian furnish us with still another example greatly enriched. The necking is ornamented with small rosaces, the echinus is sculptured with leaves, the metopes and corona are also enriched with sculpture, while the cornice resembles that generally employed in the Ionic order. The best examples of this order bequeathed to us by the Romans decorate the temple of Hercules at Cori, and the theatre of Marcellus at Rome. The former, however, is almost wholly Greek. In the latter example, the column, composed of shaft and capital, is about eight diameters in height. The capital, occupying about one half of a diameter in

height, may be divided into three nearly equal parts. The uppermost, given to the abacus, of less projection than in the Grecian examples, is crowned by a cyma reversa and fillet; the ovolo supporting the abacus is a semi-torus resting on three fillets, and occupies the middle division; while the lower third is taken up by a necking which is separated from the shaft by a small torus and fillet. The shaft, less conoidal than in the Grecian examples, is without flutes, the superior diameter being about four fifths of the diameter at the base. The total height of the entablature is about one quarter of that of the column; its projection is about equal to its height. The architrave is one half of a diameter in height; the frieze $1\frac{1}{2}$ diameter. The principal difference in the distribution of the Grecian and Roman Doric frieze is in the position of the triglyph over the column at the angle. The Romans preserved the same intercolumniation throughout, and placed the triglyph directly over the column, thus forming half metopes at the angles. In the cornice the bed mouldings occupy more height than in the Grecian types, and are composed generally of a cyma reversa, dentil, and ovolo, separated by fillets. The corona is of less importance, it being sacrificed to the cymatium, which in return is of more value than in the Grecian Doric. The soffit generally bears mutules, though sometimes these latter members are dispensed with. The only examples of the Ionic order in ancient Rome are to be found in the temples of Saturn and Fortuna Virilis, in the baths of Diocletian, in the Colosseum, and in the upper order of the theatre of Marcellus. The total height of the columns varies between eight and nine diameters. The base, about one half of a diameter in height, is composed of a torus resting on a plinth, a scotia, and a second torus; the three upper members have fillets intervening. The shaft, slightly increased in diameter at one third of its height, is either plain or fluted; in the latter case the flutes, separated by fillets, are semicircular, and are 20 in number. The diminution of the shaft varies between one eighth and one tenth of a diameter. The capitals, occupying about one half of a diameter, vary; those of the theatre of Marcellus and of the temple of Fortuna Virilis are without a necking. The volutes, connected by horizontal instead of curved lines, are bolstered, and the abacus crowning the volutes is composed of a cyma reversa and a fillet. In the Ionic capitals of San Lorenzo at Rome (generally thought formerly to have belonged to the temple of Jupiter and Juno), there exists a necking. The temple of Saturn presents still a third species, the volutes being doubled and inclined at an angle of 45° . The height and projection of the entablature are nearly equal, varying between one quarter and one fifth of the height of the column. The architrave and frieze are equal in height, and are a little less than that occupied by the cornice. The frieze is either with

or without sculpture. The bed mouldings of the cornice generally consist of a cyma reversa, a dentil course, and ovolo, separated by fillets, together occupying rather less than one half of the entire height of the cornice; the corona and crown mouldings, with the cymatium, complete this order.—The whole of the Roman possessions were covered with massive structures which embodied the Roman spirit of defiance and the supremacy of the conqueror. We find everywhere in her own limits and in her possessions roads, aqueducts, bridges, ports, forums, basilicas, temples, mausoleums, palaces, baths, theatres, amphitheatres, hippodromes, naumachias, triumphal arches, cloacas,

Arch of Titus at Beneventum.

prisons, fountains, cisterns, monumental columns, villas, grottoes, and markets. During the empire, Rome was adorned with its beautiful Pantheon, Asia was endowed with many beautiful structures, and Athens itself became embellished with the famous temple of Jupiter

Ruins of the Temple of Jupiter Olympius at Athens.

Olympius. The baths or *thermæ* of Augustus, Nero, Titus, Caracalla, and Diocletian were renowned for a magnificence which was hardly surpassed even by their palaces. In fact, throughout all the Roman structures, from the palace of the Cæsars to the villas of Lucullus, Sallust, and Hadrian, the greatest display of splendor and luxury prevailed. But, of all their structures, perhaps the most stupendous was the Colosseum, capable of containing more than 100,000 spectators. It was partially destroyed in 1084, by Robert Guiscard the Norman, who conceived the idea that it was to be used as a citadel against him. Though from the ruins the popes have taken sufficient material to construct the Farnese palace, the Cancelleria, and St. Mark, the cragged and crumbling remains are still gigantic and imposing.

V. ARCHITECTURE OF THE MIDDLE AGES. The architecture of this period, although it was derived from Greek and Roman models, applied new principles, forming structures wholly different from the antique originals. Through many successive centuries the Roman school of art continued to suffer changes. From the fragments of edifices which were torn down to form new structures, arose new combinations. The transition styles which then prevailed were, from their characteristic peculiarities, designated as the Latin, the Byzantine, the Lombard, the Saxon, the Norman, and the Romanesque, together known as the old or round-arched Gothic. During the 4th century architecture had reached its lowest point. In the religious edifices of this period marked evidences exist of an utter want of artistic feeling. The sterling principles which had been the glory of Grecian and Roman schools were either forgotten or not understood. Arches with and without archivolt were made to spring immediately from the capitals of the columns. Orders were superimposed with broken entablature; in fact, this latter member was altogether done away with in some cases. Grace was wanting in the mouldings and sculpture; the different orders were employed in the same peristyle, and the whole school of architecture became a prey to the general system of innovation which then existed. During this state of things hordes of barbarians invaded every province of the empire. This universal conflict was not calculated to give a new impetus to art, nor to promote its progress. Italy, however, under the Goth and Ostrogoth rule, evinced in some measure a renewed architectural zeal. Theodoric repaired the walls and drains of Rome, reorganized the *comitiva Romana* (who guarded day and night the monumental structures of the capital), and by his own devotion to the arts, together with that of his daughter Amalasontha, revived the spirit of a fast perishing craft.—After the transfer by Constantine of the imperial seat to Constantinople, the arts were again successfully cultivated by the Greeks, who made free use of the architectural

treasures left by the ancients. Then appeared the dome, the glory of the Byzantine school, supported by its pendentives highly ornamented with mosaic. This principal feature of the Byzantine school induced their architects to abandon the Latin cross (which form had gradually grown out of that of the Roman basilica) in the plan of their churches, introducing instead the Grecian cross, whose branches are of equal length. The dome no longer rested on circular walls, but was borne by four arches resting on pillars placed at the four angles, in plan. Pendentives were introduced in order to sustain the circular dome, as otherwise the triangular space in the four corners would have been left without support, the diameter of the dome being equal to one of the sides of the square. In some cases the corner pillars were square, presenting an angle only at the corners, thereby giving an extraordinary degree of lightness to the structure. The semicircular arch of the Romans was often elongated, in order to attain an equal height with different spans. The dogmas of the iconoclasts obliged the architects to seek some other means than sculpture of enriching their temples; hence the profusion of mosaic work. Their ornaments represented foliage in bass-relief and interlaced lines. The capitals of the columns were square blocks similarly carved, tapering down at angles to join the circular shaft. Under Narses and Belisarius the dome was introduced into Italy. The Byzantine style, whose chief promoters were Anthemius of Tralles and Isidorus of Miletus, also became the basis of the new Persian, Russian, and Saracen schools. We find its peculiarities existing during the middle ages in Greece, Italy, Sicily, Spain, Arabia, and India. Among the chief edifices of the Byzantine school are St. Mark's at Venice, San Vitale at Ravenna, and St. Sophia at Constantinople, the last being one of the most magnificent of the eastern empire.—The Saracens and Moors introduced into Europe certain forms of architecture which, though differing in very many features from the classic styles, were still founded on the remains of the Grecian school, blended with the oriental elements of the Byzantine. The chief peculiarity of these styles was in the form given to the arch. The Saracenic arch was of greater depth than width. The Moorish style was distinguished by arches in the shape of a horse-shoe or a crescent. The Saracens and Moors are, however, so completely one people, that it is with difficulty that the differences of their essential features can be discriminated. Their mural ornamentations, styled arabesque, presented more varied designs of graceful and ingenious combinations of geometrical and floral traceries than had before been known. The reproduction of animated forms was prohibited by the Koran. Another striking feature of this school is the peculiar way in which they ornamented their pendentives, by a series of little niches placed one above another, covering not only the surface of the in-

ner projecting angles, but forming at times the superentablature of the edifice. The numerous mosques, palaces, bazaars, tombs, and other edifices of the Moslems, existing throughout

Interior of the Golden Gateway at Jerusalem.

various parts of Europe, Asia, and Africa, attest the great similarity existing between this style and the Byzantine; this has been attributed to the employment of Greeks on their works. A fact worthy of note, also, is that the Moslem structures furnish examples of the pointed arches, whence according to many they were brought into Europe.—The Lombards, having possessed themselves of the northern part of

Pillar in Church of St. John. Constantinople.

Italy after the middle of the 6th century, there founded their kingdom. Converted to Catholicism, they adopted the arts of the people they had vanquished; and, as in Lombardy there existed but few ancient temples whose materials could be employed in other structures,

we find them originating a complete and systematized style, which at length pervaded all districts where the Latin church had extended its influence; the people of each country where it was introduced modifying it to suit their climate, customs, and wants. Its branches are variously known as the Merovingian, Carlovingian, Saxon, Norman, &c., which together were styled old Gothic, and out of which grew the pointed style, after the introduction into Europe of the pointed arch. During this epoch plain, banded, fluted, and polygonal columns, in spiral or zigzag, were clustered, broken, or knotted together. Their capitals were foliated or had various grotesque animals sculptured on them; they were supported on brackets variously carved, or rested upon the backs of animals, which replaced the pedestal. Every license was taken with the entablature, even to the suppression of it altogether. Against the jambs of arched openings were often placed numerous columns supporting the arched mould-

North Transept Window, Lincoln Cathedral.

ings. Oftentimes a greater arch encompassed several smaller ones, supported by pillars which intersected each other in various ways. Their openings were quite elongated and often coupled; the circular window, or rose, was also very frequent in their frontispieces. Semi-circular, elongated, flat, horseshoe, and foiled arches are to be found, ornamented and simple, and either served as a decoration, crowned their walls, or supported horizontal bands, dividing into panels their walls, which were likewise panelled off by long pilasters or flat buttresses. The angles of their churches (generally in plan in the form of the cross) were often surmounted by a sort of pinnacle. Ribs are also found in their vaulted ceilings. Towers first accompanied the churches; later they formed a part of the same edifice, flanking or decorating the middle of the façade. The earlier examples were square; later they were round, and later still of a polygonal form. The

roof, assuming a more and more pointed shape, approached the form of the spire, as it was introduced in countries where the climate was more severe. The monasteries and convents generally contained an interior court surrounded by porticos, about which were placed the cells of the inmates. The lower stories of the royal palaces and town halls presented a similar disposition. External porticos, or lodges, also existed. During this period it is supposed that the construction of houses in stories became general. The habitations of the mass of the people were poor and irregularly planted about the town hall in the cities, or clustered

Celtic Gothic Cloister, Kilconnel Abbey, Ireland.

about the massive feudal castles. These edifices consisted of a main tower, or keep, the walls of which were from six to twelve feet thick, with windows, consisting of holes one or two feet wide, placed at irregular intervals. The several floors were constructed on arches; the roof was flat, or had battlements, and possessed a notched parapet for the purposes of defence. The main tower was surrounded by a courtyard protected by a high wall, and the arched entrance was strongly secured by a falling gate or portecullis. Around the whole was a deep ditch, or fosse, which could be filled with water. Many of the castle fortresses were on a plan of great magnitude, consisting of two or more towers and divers inner buildings, including chapels.—While the whole of Europe was convulsed with the international and social strife and invasions of barbarians which resulted in its complete reorganization, the study of the arts, sciences, and literature took refuge in the monasteries. The influence of the clergy declined, however, as free institutions arose, and the pointed Gothic must be regarded as the work rather of secular than of clerical architects. This change was doubtless made more complete by the increasing importance of the fraternity of freemasons. In Italy during the 10th century we find the corporation of *magistri comacini* exercising great influ-

ence, and giving to Grecian artists shelter from the political troubles of the East, and from the persecutions of the iconoclasts. These artists promulgated among the Lombards the Byzantine elements of design, whose influence, as we have seen, was more or less felt throughout the architectural schools of Europe. Under Erwin von Steinbach of Germany, during the 13th century, the *Hütten*, or lodges, were organized, one object of which was the study of architecture, over which they exercised a powerful influence. In Strasburg existed the *Haupt-Hütte*, or main lodge. Under Jost Dotzinger of Worms (who in 1444 succeeded the architect J. Hult), the various sects of the German freemasons were incorporated into one body, and, in virtue of an act passed at Ratisbon the same year, the architect of the cathedral of Strasburg was elected the sole grand master of the fraternity. These *magistri lapidum* were likewise sole directors or supervisors of all the religious structures. Protected by the church, architecture in their hands passed from the old Gothic through various phases of the pointed style. The spirit of the age seems embodied in the Gothic cathedral, the work of minds inspired with solemn and devotional feelings. The cathedrals in the pointed style most justly deserve admiration. The pointed style is customarily divided into three periods: the first, or primary, dating from the latter end of the 12th century; the second, or decorated, or rayonnant, from the commencement of the 14th century; and the third, or perpendicular, or flamboyant, from the end of the 14th to the 16th century. The essential element of this style is the pointed arch. Were it not for this feature, it would be often difficult to distinguish between the earlier works of the first period of the pointed and the later works of the old Gothic. It is during the first period that the spire surmounting the tower becomes of so great importance, forming one of the striking characteristics of this style. In the finer examples it is octagonal and very pointed, either plain or ribbed, sometimes pierced, sometimes crocketed, and invariably bearing a finial. Buttresses and flying buttresses also form a striking feature; these latter being somewhat massive and heavy at first, but gradually becoming more and more elegant as they approached the second period. The set-offs are formed by inclined slabs, or by a pediment with finial, the face of the buttresses being ornamented at times with panels and niches; in some cases also the space between the arches of the flying buttresses is occupied by radiating columns. The parapet is uninterrupted, and is either decorated or plain. Turrets were either square or octagonal, their pinnacles being mostly of the latter form, either crocketed or not. The rose windows of this period are quite simple; small columns radiating from the centre receiving foiled arches tangent to the circumference. The lancet arch predominates. The windows are very long and narrow, and are either simple or coupled, in

which latter case a slender column forms, as it were, the mullion. The ribs of the groined ceilings are decorated with bosses at their intersections, and rest either upon corbels, or

Flying Buttress, Chapter House, Lincoln.

upon the shafts of slender columns which descend to the pavement. The piers are either simple in plan, or present several shafts clustered around a core of a circular, elliptical, or cruciform shape. The sculpture, wherein the national flora is introduced, supersedes altogether the ornamentation previously employed; rosaces, trefoils, quatrefoils, and panelling are introduced to ornament their works in various ways. During the second period the style reached its noblest development. A greater elegance and richness pervade this period, whose characteristic features are thereby distinguished from those of the previous one. The flying buttresses are extremely graceful, those at quoins being placed diagonally. The parapets are pierced or embattled, as are also the pediments. The windows gradually assume a less pointed form, the head of the arch being in general equilateral. Replacing the small columns in the windows are moulded mullions, which form graceful flowing traceries in the head of the arch. The drip-stone is often surmounted by a canopy or pediment resting on masks, and enriched with crockets and a finial. The clustered columns composing the columnar piers are more elaborate, and generally placed diagonally. Their bases become more important, and are placed upon octagonal plinths clustered together. The ribs, bosses, and carved ornaments throughout have more relief and are more elegant. The third period is remarkable for its profuse ornamentation. The panelled walls, with their niches, tabernacles, canopies, and screens, highly decorated, the flying buttresses enriched with pinnacles and tracery, the corbelled battlements and turrets, and the balustrades intricately carved and pierced, are characteristic of this

epoch. The arch presents many varieties of form. Together with those common in the preceding periods, others exist very depressed, being in many cases almost flat. The ogee, or contrasted form, also appears in the openings and pediments. The doors are generally square-headed, the spandril above being enriched with traceries. The rose windows during the 15th century are most intricate in tracery. The ground vaults also are very elaborate, while their bosses and pendants are unequalled for their wonderful carvings. The mouldings of the archivolts, more prismatic in their forms than in the previous periods, continue down uninterruptedly to the foot of the openings, thus doing away with the columns heretofore employed. The appellations of perpendicular and flamboyant, by which this period is also known, arose from its peculiar modes of tracery. VI. THE RENAISSANCE OR REVIVAL. With the reformation came the gradual abandonment of the pointed styles, accompanied as it was by the check of freemasonry occasioned by the withdrawal of the patronage of the pope. The consequent architectural reaction sprang less from admiration and a thorough knowledge of the classic styles than from necessity. The return, however, to the rules of the ancient schools of design was progressive, save in Italy, where they had constantly exercised a powerful influence over the artistic spirit, the architecture of the country having retained through the middle ages the characteristics of the classic schools. We find here, however, several beautiful edifices, termed by the Italians *in maniera Tedesca*, which, notwithstanding a contradictory statement made by Muratori and Maffei, were the work of German artists. During the 14th century, or the *trecento* period, we discover in Italy, in the secular structures more especially, numerous examples exhibiting a return to the classic styles, which possess simplicity and boldness. At length, in the 16th century, the classic taste prevailed throughout Europe, and hence the different names, *cinque cento*, *renaissance*, revival, given to that style which supplanted everywhere the so-called Gothic architecture. Brunelleschi of Florence, who died in 1444, was among the first to encourage and disseminate this taste for a return to the classic architecture. He had numerous distinguished followers, among whom were Alberti, Bramante, Peruzzi, Sangallo, San Micheli, Palladio, Seamozzi, and many others, who obtained a well deserved reputation. In their productions the different elements of the classic style are happily introduced. The application of these elements to ecclesiastical, and more especially to secular structures, accounts for the liberties taken with them, among which we will cite the following: the great variety given to the intercolumniation of columns; the superposition of different orders, with and without broken entablatures; the frequent use of engaged columns and pilasters; the various

forms given to the pediments; the substitution of columns for piers supporting arcades; the decoration of blank walls with medallions, foliage, and scrolls of various sorts, together with

Decorated Arch (Gothic), Dorchester, Oxfordshire.

designs of animals arranged in imitation of ancient arabesques. These and many other so-called liberties originated a style peculiarly well adapted to the wants of modern civilization. Michel Angelo made several innovations in architecture, as well as in the other arts. He abolished many capricious ornaments; and instead of superimposing several orders, distinguishing as many stories, he employed one, comprising the whole height of the edifice. To him we are indebted for certain bold elements of design, although generally wanting in grace and purity. To his followers, Bernini, Boromini, Fontana, and others, is to be attributed in a great measure the decadence which followed the architecture of the 16th century. From Italy the renaissance was introduced into France. Among those who distinguished themselves in this kingdom were Pierre Lescot, Philibert de Lorme, and Jean Bullant. Later appeared De Brosse, Androuet du Cerceau, and finally Perrault, under Louis XIV. England boasts Inigo Jones, her Palladio, followed by Christopher Wren, Sir Robert Taylor, Sir William Chambers, and many others of merit and distinction. VII. MODERN ARCHITECTURE. The admirable architectural forms brought in

by these men continue in use in all civilized countries to this day, and have been carried wherever European civilization has extended. Their reign has not, however, been undisputed. The spirit of scientific inquiry which has characterized the last hundred years has not only enlarged our knowledge of architectural forms, but has promoted a more exhaustive study of the principles of the art. New movements have accordingly arisen, avowedly actuated by these researches, directed either to improving the so-called classical style, or to supplanting it altogether. These two movements are known as the Greek and the Gothic revival. Both took their origin in England. The Greek revival dates from 1762, when Messrs. Stuart and Revett published the results of their researches among the antiquities of Attica. The Gothic revival may be said to date from Horace Walpole's works at Strawberry Hill about 100 years ago, but its modern development did not begin till about 1820. In England and the United States the Greek revival was merely a reproduction of the Greek buildings or parts of buildings, which, however beautiful in their original position, proved in the more gloomy climate of the north, and when executed in coarser materials, uninteresting and unattractive. The Greek originals, moreover, were almost exclusively temples, without windows, and surrounded by columns, a model utterly unsuited to modern uses. The attempted adoption of Greek details proved equally unsatisfactory. The movement made considerable mark in England, the British museum being perhaps its chief example. In this country the Greek style was adopted for the public buildings at Washington and for post offices, custom houses, hotels, and banks, in marble or granite, in all our principal cities. This fashion, for government buildings at least, has not yet passed away. Imitations of these works in wood were very common in the first half of this century, as may everywhere be witnessed in country towns; and a certain style of church with Greek details and a tower imitated from the choragic monument or the temple of the Winds is still common. In joinery, the Greek forms of mouldings both here and in England have become almost universal. In other countries the excitement caused by the discovery of Greek art was less superficial, and proved a more efficient inspiration. In Scotland, where the architecture has always exhibited much independence and local character, the "Greek" style, in the hands of Mr. Hamilton and the Adams brothers, shows great freedom of treatment and refinement of taste. More recently, in the hands of Mr. Thomson, at Glasgow, it has developed, with great elegance and beauty, forms perfectly adapted to modern uses. A similar effort was made in Germany, chiefly in Berlin and Munich, to reconcile the methods of the Greeks with modern needs; and in spite of a general effect of bareness and hardness, it is impossible to deny

to the best works of Schinkel and Klenze a good measure of admiration. It was only in France, however, in an atmosphere at once thoroughly artistic and highly intellectual, that the Greek revival showed enough vigor to throw aside the methods of the ancients and to create new forms. The pedantic fashions of the first empire, which however hardly extended their influence in architecture beyond the schools, gave place in the reign of Louis Philippe to a new style, which has been called the *néo-grecque*, or, to distinguish it from the Romanesque, founded upon Roman methods, the *romantique*, though it has little in common with the contemporary romantic school in literature. The column of July, parts of the Palais de Justice, the Bibliothèque Ste. Geneviève, and the Palais des Beaux Arts, by MM. Duc, Labrousse, and Duban, are the typical monuments of this style. Their erection marks a new era in architecture. Hardly a building of note has since been erected in France which has not been more or less affected by their example, and it has sensibly modified the related forms in use in Germany. The influence of this style is also extending in the United States, mainly through the agency of the *école des beaux arts* of Paris, whose pupils or pupils' pupils are rapidly multiplying here. Meanwhile in England, the Greek movement having failed, surviving only long enough to kill the Roman classical style, the field was left open for the revival of the mediæval architecture, which, fostered by ecclesiastical patronage and by archaeological studies, has during the last 50 years gradually engrossed nearly all the talent of the country. Beginning, as the Greek revival began, with a period of pedantry and purism, under the guidance of the elder and younger Pugin, and used at first chiefly for ecclesiastical buildings, the ascendancy of the Gothic style was finally established when in 1840 it was decided to adopt it for the new houses of parliament. This great undertaking educated a large body of workmen in all the decorative arts of the middle ages, and gave an immense impulse to the Gothic movement. Subsequent works show not only greater knowledge and skill, but more freedom of mind, both in secular and ecclesiastical work. The works of Scott, Waterhouse, Street, Burges, and Butterfield exhibit this gradually increasing tendency. It may fairly be said that in the hands of these architects the "Victorian Gothic," as it has been called, differs as much from the various Gothic styles of the middle ages as they differ from each other. A similar movement has meanwhile been going on in France and Germany, but less successfully. In Germany, after long and not altogether happy efforts to revive round-arched or Lombardic styles, the proper pointed Gothic has been taken up, stimulated by the great works for the completion of the Cologne cathedral. The Votive church at Vienna is perhaps the most noteworthy ex-

ample of this movement. In France a taste for mediæval work has found its chief field in the restoration, often amounting to reconstruction and completion, of cathedrals and other monuments; a work which, in the hands among others of MM. Lassus and Viollet-Leduc, has been performed with consummate knowledge and skill. The new buildings in the pointed style seem, however, timid and ineffective, and it is in the Romanesque or round-arched Gothic that the French seem most at home. Its influence is seen not only in works avowedly mediæval, but much of the new Greek work so called, especially that in which the arch is used, recalls these models. The adherents of the Gothic revival in this country are as numerous and devoted as those of the Greek revival. But there is less partisanship here, perhaps, than abroad, and it is more common for architects to practise in both ways at once.—See Fergusson's "History of Architecture," Durand's *Parallèle*, Napoleon's *Égypte*, Stuart and Revett's "Attica," Letarouilly's "Rome," Viollet-le-Duc's *Dictionnaire*, Eastlake's "Gothic Revival," and the works of Piranesi, Gailhabaud, Penrose, Pugin, Ruskin, Daly, &c.; also "The Builder," *Revue générale d'architecture*, &c.

ARCHON (Gr. ἀρχων, ruler), a chief magistrate of ancient Athens, first chosen instead of a king after the death of Codrus, about 1068 B. C. Medon, the son of Codrus, was the first archon, and the office was hereditary in his family till 714 B. C., when it was thrown open to all the eupatridæ or patricians. Previous to 752 B. C. the archon held his office during life; at that time his term was limited to ten years, and in 683 to one; and at this latter epoch the office was divided among nine persons. Several years afterward the archonship was made accessible to the citizens generally, who were subject, however, to some restrictions as to qualification. The power of the archons became limited by degrees, and at last they had very little influence in the management of the government. One of the nine was called the archon, as being the chief of the whole body, and his duty was to superintend the greater Dionysiac festivals in honor of Bacchus, and the Thargelia in honor of Apollo and Diana, and to exercise a general care over orphans, and jurisdiction in matters relating to the law of inheritance. He was sometimes styled eponymus (ἐπώνυμος, one from whom something is named), because he gave the designation to the year, as did the consuls at Rome. The second archon was entitled king (βασιλεύς), as he occupied the place of the ancient kings with regard to all public religious worship. The third archon was called polemarch (πολεμαρχος, commander-in-chief), and originally had supreme control over the army; at the battle of Marathon we find him in command of the right wing. But it was at length found inexpedient to intrust this important function to a person chosen by lot; and after the bat-

tle of Marathon (490) the polemarch ceased to exercise such authority, his duties being in aftertimes confined to attending to the affairs of the alien residents of Athens, to the management of the funeral games in honor of Athenians who had fallen in battle for their country, and the superintendence of other similar rites. Each of these three archons was allowed two assistants, whose appointment had to be sanctioned by the senate. The rest of the archons were styled thesmothetæ (*θεσμοθέται*, lawgivers), though this name was also sometimes applied to the whole body. At the expiration of their year of office, the archons were obliged to submit to an examination as to the manner in which they had performed their duties, and, if such examination proved satisfactory, were admitted members of the court of the Areopagus.

ARCHYTAS OF TARENTUM, an Italian Greek philosopher, mathematician, general, and statesman, in the early part of the 4th century B. C. He is said to have been seven times general of the Tarentine forces, and to have always been victorious. He evinced no less capacity in political affairs. He was very intimate with Plato, was the first who applied mathematical principles to practical mechanics, and constructed various machines and automotons. He was accidentally drowned while crossing the Adriatic. A collection of the works ascribed to Archytas will be found in Orelli's *Opuscula Græcorum*.

ARCIS-SIB-AUBE, a town of France, in Champagne, department of Aube, 16 m. N. by E. of Troyes; pop. in 1866, 2,820. It contains cotton and spinning manufactories and manufactories of cotton hosiery, and is an entrepot for iron and for the wooden wares made in the Vosges. Near this town, March 20 and 21, 1814, Napoleon fought the allied army under Schwartzenberg, before whose overwhelming numbers he was compelled to retreat on the second day, though rather successful on the first.

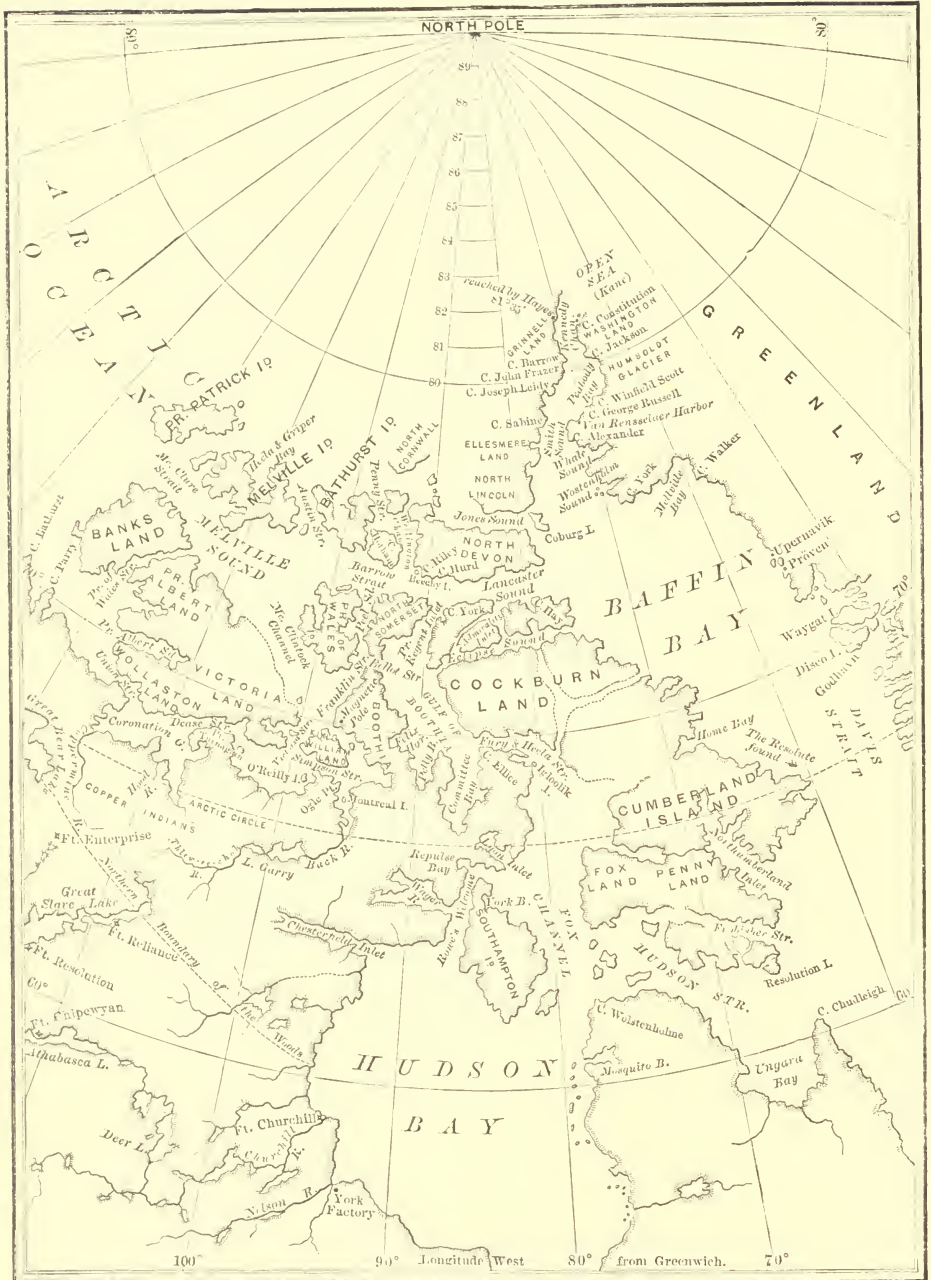

ARCOLE, a village of Venetia, on the Alpone, a small affluent of the Adige, 15 m. E. S. E. of Verona; pop. about 1,600. It is famous for the victory gained there by Napoleon in his first Italian campaign, over the Austrians, Nov. 15-17, 1796.

ARCOS DE LA FRONTERA (anc. *Arcobriga*), a town of Spain, in the province and 29 m. N. E. of Cadiz, situated on the Guadalete; pop. 11,500. The town is in a very strong position, and portions of its ancient walls and towers remain.

ARCOI. I. A district of the Carnatic, in the presidency of Madras, British India, divided into two collectorates, North and South Arcot, and lying between lat. 11° and 14° N. and lon. 78° and 80° E.; area, 12,459 sq. m., of which North Arcot contains 7,526, and South Arcot 4,933; pop. 2,638,174. The surface is low in the eastern part, but rises into hills in the western. The principal rivers are the Palaur, the Punnair, and the Coleroon. The climate is exceedingly hot and dry, and in the summer the beds of

many of the streams are bare. This has led to the construction of huge tanks or artificial lakes, of which there are many in North Arcot; one at Caverypauk is 8 m. long and 3 m. wide. The soil when well irrigated produces good crops, principally of grain and cotton. Arcot was ceded to the British in 1801, on condition that they should pay the claims of the creditors of its former ruler, Azim ul-Omrah, nabob of the Carnatic. The committee appointed to investigate these claims found them immense, and a large sum from the annual revenue of the district was set apart for their payment. The finances of Arcot, especially under the mal-administration of Hastings in India, while the province was partially conquered, but before its cession, had long before formed a subject of discussion in the English parliament, and concerning them Edmund Burke made one of his most famous speeches, Feb. 28, 1785. **II.** The principal town and capital of the preceding district, on the S. bank of the Palaur, 65 m. W. by S. of Madras; pop. about 60,000. It is surrounded by a wall; and the town itself is of comparatively modern construction, though a fortress, now partially destroyed, has existed for centuries. In 1751 Clive withstood here a remarkable siege of 50 days.

ARCTIC DISCOVERY. Until within a recent period it was believed that Columbus and Cabot were the actual first discoverers of the American continent. Careful researches on the part of northern antiquaries, however, would seem to prove that portions of the American coast—some maintain as far south as what is now Long Island—were known to the seamen or sea kings of Norway as early as the 9th and 10th centuries. Newfoundland and Greenland were the regions best known to these rovers. In 1000 a Norwegian, with a crew of Icelanders, landed on the coast of Massachusetts, which he named Vinland. This party erected monuments on an island in Baffin bay, where they were discovered in 1824. They established colonies on the Greenland coast, which flourished for some years, making great gains by the fisheries, which they pursued as far as Lancaster sound, and even to Barrow strait. Greenland and Spitzbergen were for several centuries prosperous colonies. Iceland, then at the height of its prosperity, found here a fair field for the enterprise of its inhabitants, who not only followed commerce and the fisheries, but propagated their faith in the new land, and built up numerous churches and convents, whose ruins are still found along the Greenland coasts. The Icelanders and Northmen, then, were the first arctic explorers. As the Greenland and Spitzbergen colonies perished, and the most important Icelandic expedition was lost and never heard from, while Iceland itself and the countries of the north were distracted by internal troubles, no trace of the discoveries made by these people was communicated to the rest of Europe. In 1380 two Venetian navigators, Zeni by name, voyaged to

the north, and brought back tidings of what they had seen. Their discoveries, however, resulted in nothing important. In 1497 the Cabots, John and Sebastian, landed in Labrador, and afterward projected a voyage toward the north pole. They penetrated as far as $67^{\circ} 30' N.$, that is to say, about half way up Davis

strait. They hoped to sail westward around the northern extremity of the American continent, and thus reach the much desired Cathay. These, then, were the first seekers for the north-west passage. The next explorers were the brothers Cortereal, who made in all three voyages, extending as far as $60^{\circ} N.$, but result-

ing in nothing but disaster to the adventurers and loss of life. This was in 1500-1502. In 1553 Sir Hugh Willoughby was sent out by the Muscovy company to find a northeast passage to Cathay and India. He penetrated to Nova Zembla, but was driven back by the ice as far as the mouth of the Arzina in Lapland, where he and his crew perished. In 1576-'8 Martin Frobisher made three voyages to the northwest. He discovered the entrance to Hudson and Frobisher straits leading into Hudson bay. These were the first voyages on which we hear of scientific investigations being made. In 1578 Sir Humphrey Gilbert, a relative of Sir Walter Raleigh, received authority to make a voyage of discovery on the American continent; but this, too, was practically without result. Next followed (1585-'7) Davis, who made more important accessions to a knowledge of the polar sea than any of his predecessors. He first fairly discovered the strait which bears his name, and surveyed portions of the coast of Greenland. These and other navigators, Danes, French, and Dutch, were stimulated to energetic efforts for finding a northern passage to India, in great part because Spain, then in her glory and power, monopolized the traffic across the Atlantic and Indian oceans, and dealt summarily with all intruders.—The Dutch persevered in their search for a northeast passage. William Barentz made three voyages in this direction, 1594-'6. He and his crew suffered much, and, so far as the prime object of their expedition was concerned, accomplished nothing material. Barentz himself perished on the third voyage, when his crew were in boats near the Icy cape, a headland of Alaska, in the Arctic ocean. Henry Hudson set out in 1607, under the auspices of the Muscovy company, with orders to steer directly toward the north pole. He advanced beyond lat. 80°, steering due north between Greenland and Spitzbergen, and returned convinced that a passage in that direction was impossible. The following year (1608) he tried to discover a northeast passage to India, between Nova Zembla and Spitzbergen. He pushed forward as far as lat. 75°, and returned the same year. The next year he tried again, but, finding his way impeded by ice, returned and sailed westward, and, searching along the American coast for a passageway, discovered the bay of New York and the river which bears his name. In 1610 Hudson set sail upon a fourth expedition. He sailed up the strait named after him into the mouth of Hudson bay, penetrating several hundred miles further to the west than any one had ever gone before. The expedition wintered on one of the islands in the mouth of the bay. Their progress in the spring was beset with storms, the provisions gave out, the crew mutinied, and finally a portion of the mutineers returned to England without Hudson, whom they set adrift to perish.—It was now supposed that Hudson bay was a great outlet into the Pacific waters, and san-

guine expectations were entertained that here would be found the desired northwest passage. Within the next five years several expeditions were made into Hudson bay; and two important channels, Fox channel and Sir Thomas Rowe's Welcome, were partially explored. In 1616 Baffin explored the bay called after him, even entering the mouth of Lancaster sound. Baffin's survey was very exact, and for upward of 50 years after his explorations no navigator penetrated beyond him. Meantime, however, the Russians were seeking, by overland expeditions through Siberia, and by vessels through Behring strait, to establish the practicability of a passage to the northeast. On one of these expeditions the extreme variation of the magnetic needle was first closely remarked. In 1741 Behring set sail with an expedition from the harbor of St. Peter and St. Paul (Petropavlovsk) in Kamtchatka. After various buffetings before severe gales, having twice made the American coast and been driven off to sea, Behring died; the vessels were wrecked; the crews wintered on an island known as Behring island, built a small vessel the following spring, and finally reached Kamtchatka Aug. 25, 1742. Only a bare mention can be made of the expeditions of Shalaroff (1760), who perished of starvation with all his crew; of Andreyeff; and of Capt. Billings, who started from the mouth of the Kolyma in Siberia. None of these resulted in important additions to the stock of geographical knowledge; and so we come to the last of the Russian efforts—the sledge expeditions of Von Wrangell and Anjou, in 1820-'23. These explorers penetrated to lat. 70° 51' N., lon. 157° 25' W., and reported an open sea in the distant north, which precluded further operations with sledges. The natives whom they met at various points spoke of land still further north, but they did not see it.—Hudson bay was yet considered a great outlet toward the northwest, and in 1743 the British parliament offered a reward of £20,000 to the crew who should accomplish a northwest passage through it. Between 1769 and 1772 Samuel Hearne made three overland journeys north toward the polar sea. In the third he discovered and traced to its mouth the Coppermine river. From this time forth the arctic explorations were no longer merely for purposes of advantaging commerce, but in great part for scientific objects. In 1773 Capt. Phipps (Lord Mulgrave) was sent out with instructions to reach the north pole. Sailing along the shores of Spitzbergen, he reached lat. 80° 48'—about as far north as Hudson had gone. In 1776 Capt. Cook sailed on his last expedition, with instructions to attempt the polar sea by way of Behring strait. He penetrated only to lat. 70° 45'. A vessel was despatched to Baffin bay to await him, but the ice formed a solid barrier across his path. Previous to Cook's expedition the conditions of the parliamentary reward had been extended so as to include any northern passage for ships, and an

additional reward of £5,000 was offered to the crew that should penetrate to within 1° of the pole. In 1789 Mackenzie, in a land expedition, discovered and traced to its mouth the river called after him.—The next two expeditions set sail in 1818; one under the command of Capt. Ross and Lieut. Parry, to discover the north-west passage; the other under Capt. Buchan and Lieut. (Sir John) Franklin, to penetrate to the north pole. Of the latter expedition the objects were entirely scientific. The commanders were instructed to pass northward between Spitzbergen and Greenland without stop, and to make every effort to reach the pole. They found the temperature along the western shore of Spitzbergen unexpectedly mild; but they did not succeed in penetrating further than 80° 34', and did not get clear of the ice without encountering great danger. One of the ships, the *Dorothea*, being much shattered by the ice, the expedition was finally abandoned, and the two vessels returned home. With the other expedition it was proposed to explore the great openings reported by Baffin to exist at the western extreme of Baffin bay. The expedition sailed April 18, 1818, passed along the Greenland coast, and finally, Aug. 30, entered Lancaster sound. They were now upon unexplored ground. It was not supposed that Lancaster sound was in point of fact more than a bay, and the vessels were steered into it with many misgivings. After sailing up some 60 m. it was thought that land was discovered, extending completely across from shore to shore of the supposed bay; and, the weather threatening a storm, the vessels were put about. After exploring the coast to the southward and eastward for some distance, the vessels returned to England, where they arrived in October of the same year. Capt. Ross reported Lancaster sound to be a bay through which there was no practicable outlet to the ocean beyond. In this opinion several of his officers by no means agreed; and it appears that he failed to convince the scientific public of England of the correctness of his view.—Lieut. Parry, who was as positive and sanguine that Lancaster inlet was a sound as was Ross that it was a bay, was intrusted with another expedition. The *Hecla* was his own vessel. The *Griper*, under the command of Lieut. Liddon, was the consort. The expedition numbered 94 men, and was fitted out with provisions for two years. The vessels sailed May 11, 1819, first fell in with ice June 18, and found themselves firmly beleaguered on the 25th. They entered Lancaster sound July 30, but it was not till Aug. 3 that both vessels were able to lay their course fairly up the channel. Then they made a rapid run as far as the mouth of Barrow strait, and on passing the mouth of Prince Regent inlet had advanced further than any mariners had ever gone before them. They were approaching the magnetic pole, and found their compasses of little use. Proceeding through Melville

sound, on Sept. 4 Parry announced to his crew that, having passed the 110th meridian, they were entitled to the reward of £5,000 offered by parliament for this achievement. On Sept. 20 they were imbedded in ice, and further progress was stopped. They cut their way out and returned to Melville island, where they passed the winter. On Aug. 2 of the following year the mass of ice broke up and floated out, setting the explorers at liberty. By the 15th they were again imbedded in ice, having made but little advance. They finally put about for home, reaching Britain in safety, and with the crews in a healthy condition. So successful a voyage raised high the expectations of all interested, and it was determined to send Parry out again. He accordingly sailed, in command of the *Hecla* and *Fury*, in May, 1821, with instructions to make for Repulse bay by way of Hudson strait, with the expectation of thus avoiding much of the ice.—Before this, however, in September, 1819, an overland expedition was sent out from York Factory, on the western shore of Hudson bay, with instructions to explore the northern coast of America, from the mouth of the Coppermine eastward. This expedition consisted of Lieut. (Sir John) Franklin, Dr. (Sir John) Richardson, two midshipmen, Messrs. Hood and Back, and a seaman named Hepburn. In the event of Parry's making the coast on his first expedition, the two expeditions were to cooperate. They reached Chipewyan on March 26, having accomplished a foot journey of 856 m. with the weather so intensely cold that the mercury sank to the bulb of the thermometer and then froze. In July, 1820, they travelled 500 m. more to Fort Enterprise, where the party wintered, while Mr. (Sir George) Back returned to Fort Chipewyan, to hurry along the supplies necessary for the next season's operations. Mr. Back, after innumerable hardships, returned to Fort Enterprise March 17, 1821, having travelled over 1,100 m., sometimes two or three days without tasting food, with no covering at night but a blanket and deerskins, and with the thermometer ranging between 47° and 57° below zero. On June 30, 1821, the party having dragged their canoes and supplies from Fort Enterprise to the Coppermine, 80 m., embarked on that stream and floated seaward. They reached the sea July 18, and immediately commenced paddling to the east. They sailed and paddled along shore 550 m., and imagined themselves upon the point of emerging into the vast Arctic ocean, when, to their dismay, they discovered that they had just reached the bottom of a huge bay. With but three days' provisions remaining, they turned back, Sept. 1, and, unable even to reach their starting point, built two small canoes of their larger ones, and ascended Hood river, a short distance west of Point Turnagain, the spot where they gave up further progress eastward. Short of food, in a country deserted by animals, ill provided with all that could

facilitate their progress, eating the remains of their old shoes and whatever scraps of leather they had, obliged from exhaustion to abandon their canoes when they came to rapids, subsisting at the last upon rock tripe and mosses, disappointed in finding assistance at a station where they had expected it, the sufferings of the party were almost unparalleled, and such as but few men could have endured. They lost two of their companions, and in July, 1822, reached York Factory, whence they had started three years before. In these three years they had made a journey of over 5,500 m., without accomplishing their object.—Meantime, Captains Parry and Lyon, in the *Fury* and *Hecla*, made Southampton island, the terminus of Hudson strait, early in August, 1821, and immediately steered to the north up Fox channel. Passing a bay hitherto unknown, which they named after the duke of York, they entered Repulse bay, in the hope of finding here an outlet toward the Arctic ocean. Leaving Repulse bay, they started upon the exploration of a hitherto entirely unknown region. They made slow progress, exploring every indentation of the coast. Toward the close of September the ice began to accumulate, and Parry was obliged to cut into a large floe, and make there a winter harbor for his vessels. It was July before they were once more free of ice, and able to make progress on their voyage. They made their way up Fox channel slowly, against a current setting to the southward, and reached, Aug. 14, the small island of Igloolik, situated at the entrance of a strait called afterward the strait of the *Fury* and *Hecla*. The ships were long detained here by ice, reached the middle of the strait only in September, and were obliged to return to Igloolik for the winter, Oct. 30. The next spring (1823) proved unfavorable. The expeditions by land were able to effect but little, on account of the extreme ruggedness of the shore. The first week in August was past before the ships were released from their harbor; and Parry, who saw all advance to the north prevented, returned home, arriving in England in October, 1823.—Four expeditions were now fitted out. The first, consisting of two ships, under Parry, was to try Prince Regent inlet, which it was supposed would be found to open at its southern extreme into the Arctic sea. The second party, under the command of Franklin, was to descend the Mackenzie river to the sea, and there divide, one party turning to the east, the other endeavoring to penetrate westward, even to Behring strait. Captain Beechey, in the *Blossom*, was despatched around Cape Horn, to sail through Behring strait and make headway to the east as far as Kotzebue sound, where he was to wait for Franklin's overland party. The fourth expedition (Capt. Lyon, in the *Griper*) was to pass to the south of Southampton island, up Sir Thomas Rowe's Welcome, to Repulse bay; then to cross the Melville isthmus, and survey the coast as far as Franklin's

Point Turnagain. This expedition was unfortunate; the vessel was twice nearly wrecked, and the expedition was abandoned when yet 80 m. distant from Repulse bay. Parry's expedition sailed in May, 1824, entered Lancaster sound in September, got into the ice, and was obliged to winter in Port Bowen, near the entrance of the sound. The following July, when starting forward again, the *Fury* was wrecked, and Parry returned to England in the *Hecla*, with a double crew. The only object gained by this disastrous expedition was a contrivance whereby the compass was made to work perfectly under all circumstances, and in all places, no matter how near the magnetic pole, thus obviating a most serious difficulty in arctic navigation. This was accomplished by simply placing a small circular plate of iron near the compass.—We come now to Franklin's expedition. The officers forming his staff were Dr. Richardson, Lieut. Back, Mr. Kendall, and Mr. T. Drummond, a naturalist. They arrived at Fort Chipewyan in July, 1825; passed on to Great Bear lake, where the party were to winter; and thence a small party with Franklin descended the Mackenzie to the sea, which they reached at a point in lat. $69^{\circ} 14'$, lon. $135^{\circ} 57'$, 1,045 m. from Great Slave lake. On June 28, 1826, the whole party again started from their quarters down the Mackenzie. The expedition separated, according to the previously planned course of operations. Franklin, going to the westward, reached the sea, and penetrated as far west as Return Reef, in lat. $70^{\circ} 24'$ and lon. $149^{\circ} 37' W.$, whence on Aug. 18 he set out on his return to the Mackenzie, the weather becoming bad, and he being unaware that Beechey was waiting for him but 146 m. to the westward. The latter, in the *Blossom*, had passed through Behring strait and anchored near Chamisso island, in Kotzebue sound, on July 22. He waited here till the advancing season made further stay dangerous, and then sailed for Petropavlovsk. The following year (1827) he again anchored in Kotzebue sound, but of course did not meet Franklin's party as he had hoped. Franklin traced the coast for 374 m. from the mouth of the Mackenzie. His voyage extended over 2,000 m. The other party, under Dr. Richardson, accomplished but little. The whole expedition wintered at Great Bear lake, where Franklin instituted a series of observations on terrestrial magnetism.—In 1806 Mr. Scoresby, a whaler and private discoverer, accompanied by his son, had penetrated as far as $81^{\circ} 30'$ north, further than any one had gone before him. Buchan and Franklin so completely failed in the ship expedition in 1818, that Mr. Scoresby was led to advise an expedition to proceed by boats so fixed on sledges as to be easily dragged over the ice. Capt. Parry received the command of an expedition fitted out in accordance with this idea. Two boats, covered, well built, and set upon sledges, were to be landed upon the northern shore of Spitz-

bergen, whence they were to be dragged or sailed as ice or water presented itself. It was June 20, 1827, before Parry started with his boats, which contained 71 days' provisions. They met with many difficulties from the outset—thin ice, rough ice, short tracts of water interspersed with shorter tracts of ice, and snow-blindness among the crews. The last evil they obviated by travelling altogether at night, completely reversing the usual order of living, and for many days sleeping regularly by day and pushing forward by night. In five days of unremitting exertions, from June 24 to 29, they made but 10 m. due north. The ice on which they travelled moved to the south in a body about as fast as they could move northward, and on reaching $82^{\circ} 45'$ they gave up their attempt to reach the pole. They were then by observation distant from the Hecla 172 m. To attain this distance they had actually passed over 292 m. of ice and water; and having to make several of their days' journey over three or four times on account of the moving ice, it was calculated that they really travelled 668 m. They returned from this most discouraging and laborious expedition Aug. 21.—The object of the expedition fitted out by Sir Felix Booth, and commanded by Capt. Ross and his nephew, Commander (Sir James) Ross, in the *Victory*, a vessel fitted to use steam in calm weather, was to find a northwest passage by some opening leading out of Prince Regent inlet. The *Victory* sailed in May, 1829, entered Prince Regent inlet Aug. 9, made the scene of the *Fury's* wreck on the 12th, and on the 15th reached the furthest point achieved by Parry. During the months of August and September the explorers worked their way along 300 m. of hitherto undiscovered coast, and finally reached a point only about 200 m. distant from the extreme point reached by Franklin on his last expedition from the westward. On Oct. 7 they went into winter quarters at a place they named Felix harbor. Sept. 17, 1830, they once more got under way. After making 3 m. they again entered winter quarters, where they remained till Aug. 28, 1831. After making 4 m. (which consumed a month's time) they again, Sept. 27, went into winter quarters. It was during April, 1831, that Capt. Ross, on a sledging expedition, for the first time reached and fixed the position of the true magnetic pole. The spot was in lat. $70^{\circ} 5' 17''$, and lon. $96^{\circ} 46' 45''$ W. Scurvy appearing among the crew, it was finally deemed best to abandon the ship, and with the boats on sledges to make for the place of the *Fury's* former wreck. After almost incredible hardships they reached this spot July 1, 1832, having left their ship April 23. Here, on *Fury* beach, they were obliged to pass another winter—1832-'3. The men suffered much, and several died. They started again for the open sea July 8, 1833, and on Aug. 26 desisted a vessel, which took them on board. The captain refused at first to believe that Capt. Ross

and his crew stood before him. They had been given up for dead for two years past. On Sept. 30, 1833, they reached the Orkneys, having been absent since May, 1829.—In February, 1833, Back, with Dr. King, a naturalist and surgeon, left England for an overland expedition in search of Ross's party. They reached Fort Resolution, on the Great Slave lake, Aug. 8, passed on to the north and east, but returned to winter at Fort Reliance, where they suffered terribly from scarcity of food and a temperature of 102° below the freezing point. On April 25, when they were preparing to start for the seacoast to the north and east, they received news of the safety of Ross and his party. On June 28 they launched their boats on the Thlew-ee-choh or Great Fish (afterward called Back) river, which they hoped would take them to the polar sea. After a difficult navigation of 530 m. they reached the ocean, at lat. $67^{\circ} 11' N.$ and lon. $94^{\circ} 30' W.$, and pushed on along shore; but they met with constant impediments, and were finally, Aug. 14, obliged to turn back. The extreme point they reached was in lat. $68^{\circ} 13' N.$ and lon. $94^{\circ} 58' W.$ Back returned to England in September, 1835, and in June, 1836, set out in the *Terror* to complete the exploration of the supposed water connection between Ross's winter harbor, in Prince Regent inlet, and Point Turnagain, which Ross had so vainly attempted to reach. They were unfortunate from the first, and accomplished nothing.—Simultaneously with this expedition, the Hudson Bay company sent out two men, Dease and Simpson, to descend the Mackenzie river to the sea, and follow the coast to the west, as far as the point from which Beechey turned back to go out of Behring strait. This would complete the survey of all that part of the American shores. They reached Return Reef, Franklin's furthest point (August, 1826), in July, 1837. Beyond this no one had ever been. They reached Point Barrow, the extreme point attained by Beechey in 1826, Aug. 4, and thus completed their task. They discovered on the way two large rivers, which they called the Garry and the Colville. Returning to winter quarters on Great Bear lake, they started on another expedition to explore to the eastward, in June, 1838. Reaching the coast by way of the Coppermine, and finding their progress stopped by the ice, a portion of the party set out to the eastward on an overland expedition. Passing Franklin's Point Turnagain, the furthest point hitherto reached from the west, they discovered an ice-encumbered strait (Dease strait), and at its eastern extremity a large headland. To the north lay an extensive tract of land, now first seen, and which they called Victoria land. Surmounting the ice-bound cape, the explorers, to their surprise, found the sea beyond entirely free of ice, Victoria land stretching for 40 m. to the E. N. E., and the American coast trending to the S. E. This was the limit of their explorations in

1838. In an expedition the following year they sailed through Dease strait, and not only settled the coast line up to the spot which Back had reached in 1834, but went beyond, and explored the estuary of Back, which here forms a deep indentation in the northern coast of the American continent. In fact, they joined their discoveries very nearly to those of Ross, and were at one time within 90 m. of the place he fixed upon as the locality, during that year, of the magnetic pole.—The entire American coast, along the polar sea, was now explored, except that portion lying between Dease and Simpson's extreme point on the west of Boothia and Ross's winter quarters on the east side of the same land, and that tract lying between Ross's winter quarters and the extreme point reached by Parry in 1822, at the entrance of the strait of the Fury and Hecla. The main question now was on the possibility of passing with ships between Boothia and the American mainland, as, if this were possible, the passage down Prince Regent channel would be the easiest one for the accomplishment of a voyage to the north-west. To settle this question the Hudson Bay company in 1846 sent out Dr. John Rae. He and his party reached Chesterfield inlet July 13, 1846, passed Repulse bay safely, and conveyed their boats thence into Committee bay, at the bottom of Boothia gulf. Wintering at Repulse bay, the result asked for from their expedition was not attained till 1847. On April 5 of that year they started again into Committee bay. On the 18th they reached an inlet which Sir John Ross had before discovered, in one of his land excursions, during his two winters' sojourn on the coast of Boothia, and (Ross having established the continuity of the coast to that point) thus proved that Boothia is connected with the American mainland, and that consequently there is no outlet toward the west through Prince Regent inlet. Returning to recruit, May 12, Dr. Rae set out to explore the E. shore of Committee bay, and connect his surveys, if possible, with those of Parry (1822) in the Fury and Hecla strait. On May 27 the party reached a point from which, during an interlude in the storm, they saw a headland, which Rae calls Cape Ellice, and computes to be in lat. $69^{\circ} 42' N.$ and lon. $85^{\circ} 8' W.$, that is to say, within 10 m. of the Fury and Hecla strait. This completed the entire survey, with the exception of Fury and Hecla strait itself; and thus was finished, with this exception, a geographical exploration of the N. coast of the entire American continent, on May 27, 1847.—We come now to the last voyage of Sir John Franklin. The achievement of a northwest passage was his life dream, and to him was intrusted a new and—so it was hoped—final expedition. The Erebus and the Terror, long tried in arctic navigation, were the vessels chosen for the voyage. Each was fitted with a small steam engine and screw propeller. Sir John Franklin commanded the Erebus, Capt.

Richard Crozier the Terror. The vessels sailed May 19, 1845, in company with a tender, with additional stores. This tender was relieved and sent home in Davis strait, where the vessels were fully provisioned and equipped for a three years' stay. On July 26, 1845, they were seen by a whale ship, in lat. $74^{\circ} 48'$ and lon. $66^{\circ} 13'$, about the centre of Baffin bay, moored to an iceberg, and awaiting an opening into Lancaster sound. This is the last time the vessels were ever seen. The instructions of the admiralty directed Franklin, after sending home the transport from Davis strait, to make the best of his way to Baffin bay, and through this into Lancaster sound; then to push westward in about lat. $74^{\circ} 15'$ as far as about lon. $98^{\circ} W.$ From that point Franklin was to penetrate to the southward and westward toward Behring strait. Toward the close of 1847, nothing having been heard of the expedition, alarm began to be felt as to its safety, and early the following year (1848) three different expeditions for succor were despatched by the British government. The first of these, in the Plover, Commander Thomas Moore, and the Herald, Capt. Kellett, was to enter Behring strait, and advance at least as far as Chamisso island, in Kotzebue sound, and then to examine the coast further to the eastward in boats. The expedition was joined by the Nancy Dawson, a pleasure yacht owned and commanded by Mr. Robert Sheddon, who took a very active part in all the operations. The vessels reached Chamisso island, July 14, 1849, proceeded immediately on to Icy point, and thence sent the boat expedition on to explore, if possible, as far as the Mackenzie river. The vessels meantime stood to the north, until, in lat. $72^{\circ} 51'$ and lon. $163^{\circ} 48'$, they were brought to by densely packed ice. Still exploring, on Aug. 17 they discovered some islands, and a large body of land, in about lat. $71^{\circ} 30'$. On Aug. 24 part of the boat expedition rejoined the vessels, the remainder, two whale boats, having been despatched, according to previous instructions, up the Mackenzie river, to proceed homeward by way of Fort Hope and York Factory. The returned boats had explored the shore as far as Dease inlet, but had found no traces of the lost voyagers. The following summer (1850) the two vessels reexplored the same ground, but again without meeting with any traces of Franklin. The Plover, Capt. Kellett, was left to winter in Grantley harbor, and the Herald returned home. Meantime part of the land party, under Sir John Richardson, reached the polar sea, Aug. 4, 1848, making deposits of pemmican by the way, at convenient points, along Mackenzie river. They then explored the shore to the east for 800 m., to the mouth of the Coppermine, but found no traces of Sir John Franklin. The next summer (1849) Sir John Richardson having returned to England, Dr. Rae explored the shores of Wollaston sound, and in 1850 he repeated his explorations, but with

no more success. The third expedition, under command of Sir James Ross, sailed from England May 12, 1848, explored the S. side of Lancaster sound as far as Cape York, and thence across the mouth of Prince Regent inlet, wintered at Leopold harbor, and the following spring (1849) explored the shores of North Somerset as far as lat. $72^{\circ} 38'$ and lon. $95^{\circ} 40' W.$, concluding that North Somerset and Boothia were united by a narrow isthmus, where Bellot strait was afterward found. They also explored portions of the shore N. of Barrow strait, and both sides of Prince Regent inlet. The expedition returned to England Nov. 3, 1849, without having fallen upon any traces of Franklin. The general opinion of those best acquainted with arctic navigation, and with Sir John Franklin, was that his party was ice-bound among the islands to the westward of Melville island. Thither, therefore, were the next efforts mainly to be directed.—In March, 1849, the British government gave notice that £20,000 would be awarded to any private exploring party, of any country, which should render efficient aid to the missing explorers. In 1849 Lady Franklin had a supply of coals and provisions landed upon Cape Hay, S. side of Lancaster sound. In 1850 three new expeditions were sent out by the British government, with instructions mainly identical with those of 1848. The year 1850 was, however, to see many more expeditions than these three of the government. In fact, there were in all no fewer than eight. First on the list comes the continuation of Dr. Rae's expedition of 1849. He was to penetrate further to the north than he had been able to do before, and to examine the shores of Banks land, the coast about Cape Walker, and the N. side of Victoria land. Two smaller parties were at the same time to follow the mainland to the westward, toward Point Barrow, one descending the Mackenzie, the other the Colville. Next comes the Behring strait expedition, consisting of the *Enterprise*, Capt. Collinson, and the *Investigator*, Commander McClure. They were instructed to cruise in company as far to the eastward as they could get; to make friends of the Esquimaux; to make occasional deposits of provisions; and to prevent by every means any detention of the vessels in the ice. The *Investigator* and *Plover* (the last already in the Pacific) were last in getting through Behring strait. The Baffin bay expedition, sent out by the government, consisted of the *Resolute*, Capt. Austin, and the *Assistance*, Capt. Ommaney—sailing vessels—and the *Pioneer* and *Intrepid*, Capt. Sherard Osborn, both screw propeller steamers. The instructions to this expedition were mainly of a similar tenor to those given the Behring strait commanders. This fleet sailed in the spring of 1850. The schooner *Felix* and a small tender, the *Mary*, formed an expedition put forward by public subscription, and commanded by Sir John Ross. He sailed in April, 1850, provisioned for 18 months, and

designing to commence at Cape Hotham, at the W. side of the entrance of Wellington channel, and examine all the headlands to Banks land. Finding nothing, he then intended to leave his tender and push forward for a second season in the *Felix*. The *Lady Franklin*, fitted out by Lady Franklin, and commanded by Capt. Penny, with the brig *Sophia*, sailed also in 1850, intending to explore as circumstances should seem to direct, but having a general plan somewhat similar to the government expedition. Lady Franklin also fitted out and defrayed two thirds of the expense of another expedition, consisting of the schooner *Prince Albert*, commanded by Commander Charles Forsyth and Mr. W. P. Snow, both volunteers. Their object was to examine the shores of Prince Regent inlet and the gulf of Boothia, and to send out overland travelling parties to explore the W. side of Boothia, down to Dease and Simpson strait. The *Albert* sailed in June, 1850. The *Advance* and *Rescue*, under the command of Lieut. De Haven, formed an American expedition, fitted out by the United States government, but at the cost chiefly of Mr. Henry Grinnell of New York. This expedition left New York May 24, 1850. Its plan was to push forward without delay toward Banks land and Melville island, and generally make the best use of every opportunity for exploring in that direction. Lastly comes the *North Star*, a transport ship, containing stores for the expedition of Sir James Ross. She wintered at the head of Wostenholm sound, in lat. $76^{\circ} 33'$, further north than any vessel ever wintered except Dr. Kane's, and returned to England in September, 1850. It will be seen that there were now no fewer than 11 vessels, exclusive of the *North Star*, in the eastern arctic waters.—Capt. Ommaney of the *Assistance* came upon the first traces of the missing mariners at Cape Riley, Aug. 23, 1850. A more minute examination of the country immediately surrounding gave indisputable proof that Franklin's party had sojourned about there for some time. The site of a tent paved with small stones, quantities of birds' bones lying around, as also meat canisters, were the traces discovered at Cape Riley. At Beechey island, about 3 m. W. of the cape, and just at the entrance of Wellington channel, Lieut. Osborn finally came upon an encampment of the party—in fact, the first winter quarters of Sir John Franklin. The objects here discovered were a large number of empty meat tins, the embankment of a house, with carpenters' and armorers' working places, and other remains of a large establishment, and finally, the graves of three men belonging to the *Erebus* and *Terror*, which bore date of the winter of 1845-'6. Further on, on the island, there were the remains of a garden, and various articles of apparel lying about. Lieut. De Haven, of the American expedition, visited the place on Aug. 25, and made another thorough search. The officers of the *Prince Albert*, as

well as Capt. Penny, also examined the entire ground very minutely. Singularly, not all this searching brought to light any document which could give the slightest trace of the future intentions of the party. The government ships wintered but little distance from each other; and the spring of 1851 was devoted to land expeditions, in which the shores of Wellington channel, the coast of Banks land, and the waters leading from Barrow strait to Melville island, were to be thoroughly explored. The various parties made a thorough search on their different routes, and explored 675 m. of hitherto undiscovered coast, but found no trace of the lost. Lieut. McClintock's party reached on this occasion the furthest western limit ever attained by arctic explorers starting from Baffin bay, a point in lon. $114^{\circ} 20'$ W. and lat. $74^{\circ} 38'$. From the tameness of animals found hereabout it would seem that few if any human beings had ever touched this point before. Dr. Kane's opinion, on examining the sledge tracks about Cape Riley, was that Sir John Franklin had passed to the north, with his ships, on the breaking up of the ice in 1846; had gone through Wellington channel into the supposed great polar basin, and had never returned. The American expedition, which had gallantly led the way wherever they could go, and whose commander earned for himself at the hands of the English the sobriquet of "the mad Yankee," after undergoing much suffering and considerable danger, arrived in New York, the *Advance* on Sept. 30, and the *Rescue* on Oct. 3, 1851. On June 3, 1851, the *Prince Albert*, which had brought to England news of the discovery at Beechey island, was despatched by Lady Franklin on another expedition to explore the shores of Prince Regent inlet. She returned in October, 1853. The conclusion drawn from the failure of all the expeditions, including Dr. Rae's of 1851, which was very thorough, was that Franklin had never reached so far south as the American mainland, or the peninsulas connected with it. —Sir John Ross had brought back a report that the Franklin party had been murdered in Wostenholm sound by the Esquimaux. To establish the truth or falsity of this rumor, Lady Franklin sent the *Isabel* screw steamer, Commander Inglefield, to explore this sound. He left England in July, 1852; examined Wostenholm sound, finding no traces of the missing ones; sailed up Smith sound to lat. $78^{\circ} 28' 21''$. 140 m. further than previous navigators had reached; found, as he thought, a more genial climate than existed to the south; and established in this voyage the presence of a strait or channel connecting Baffin bay with the great polar basin. Meantime, following the Wellington channel theory, Sir Edward Belcher was sent out in April, 1852, in command of five vessels, the *Assistance*, *Resolute*, *North Star*, *Pioneer*, and *Intrepid*—the last two steamers. The *North Star* was to be the depot and store ship; the *Resolute* and *Intrepid* were to steer

west, to the assistance of Collinson and McClure; and the *Assistance* and *Pioneer* were to push up Wellington channel.—In the spring of 1853 more expeditions were sent out. The chief of these was that fitted out by Mr. Grinnell of New York, Mr. Peabody of London, and others, and commanded by Dr. E. K. Kane, who had acted as surgeon, naturalist, and historian of the former Grinnell expedition, under De Haven. Lady Franklin sent out the *Rattlesnake* and *Isabel*, steamer, for Behring strait, to assist Collinson and McClure. Dr. Rae was despatched for another exploration of Boothia. And finally, the *Lady Franklin* and *Phoenix*, Capt. Inglefield, were sent to Barrow strait, to aid Sir Edward Belcher. With Inglefield on this expedition was Bellet, a gallant young Frenchman, who was lost Aug. 18, 1853, by being blown off some floating ice. The westward expedition of Belcher made a number of explorations in the general direction of their line of search, toward Melville island. They found no traces of Franklin, but fortunately succeeded in finding and rescuing McClure and his ship's company, who had been buried in the arctic ice since the summer of 1850, three years. These returned home with Belcher, abandoning their ship, and are thus the first and only ship's company who ever entered Behring strait and returned to Europe by Baffin bay. Thus was established, at last, the great fact that there is a continuous passage by water from Baffin bay to Behring strait, parallel with the coast of the American continent. McClure reached in his ship in 1850 a point within 60 m. of the western terminus of Barrow strait, and thus had nearly passed through with his vessel. The crews under Belcher's command had meantime made extensive explorations by land during the spring and autumn of 1853, and the spring of 1854. The *Assistance* and *Pioneer* penetrated up Wellington channel to lat. $78^{\circ} 10'$, making various discoveries of new land and islands. When the vessels were brought to by ice, the officers set out on sledges, and penetrated overland to a point which Belcher considered an opening into Jones sound from the east. Here, to their surprise, as early as May 20, all sledging operations were stopped by open water. They found at various points structures of ice too well built to be the work of natives, but nowhere the slightest tangible trace of Sir John Franklin. In the spring of 1854 the vessels composing the expedition, the *Assistance*, *Resolute*, *Pioneer*, *Intrepid*, and McClure's ship, the *Investigator*, were abandoned, their crews taken on board the *North Star*, *Phoenix*, and *Talbot*, and the entire party arrived in England in September, 1854. It must be mentioned here that McClure, in August, 1850, discovered in the ear of an Esquimaux chief, near the mouth of Mackenzie river, a flat brass button. On being asked where he obtained this, the chief made answer that it had been taken from the ear of a white man who had been killed by one of his tribe. The white

man belonged to a party which had landed at Point Warren, near the mouth of the Mackenzie, and there built a house. Nobody knew how they came, as they had no boat; but they went inland. The man killed had strayed from the party, and he (the chief) and his son had buried him on a hill at a little distance. When or the exact spot where this occurred could not be ascertained. Neither the grave nor the house was found. Collinson, McClure's companion on the Behring strait expedition, eventually returned to England by the way he came. He made numerous discoveries of land, and explorations in the neighborhood of Banks land, Wollaston land, Albert land, and Victoria land. At Cambridge bay in Prince Albert sound, in about lat. 70° and lon. 117° , where his vessel passed the winter of 1852-'3, he saw in the possession of the Esquimaux a piece of iron and fragments of a hatch frame or doorway. These he thought must have belonged to Franklin's ships; but he was unable to obtain any intelligence in regard to the manner in which the Esquimaux came into possession of them.—There remained now Dr. Rae's expedition to Boothia, and Dr. Kane's American expedition, to hear from. Dr. Rae reached Pelly bay, on the S. W. side of the gulf of Boothia, N. W. of Committee bay, in April, 1854. Here he met Esquimaux who had in their possession various articles of silverware, &c., belonging to officers of both the Erebus and Terror. The intelligence obtained by him of the natives may be summed up as follows: In the spring of 1850 some Esquimaux killing seals near the N. shore of a large island known as King William land (some distance westward of Pelly bay), saw a party of about 40 white men pass to the southward, along the W. shore of this island. They were dragging a boat and sledges with them. They could not speak Esquimaux, but the natives gathered that their ships had been crushed, and they were now going where they could find deer to shoot. They purchased a little provision from the natives, who judged that they were nearly destitute of food. The officer with them was described as a tall, stout, middle-aged man. At a later date, the same season, but previous to the disruption of the ice, the corpses of some 30 persons, and some graves, were discovered on the continent, and five dead bodies on an island near it, about a long day's journey N. W. of the mouth of a large river supposed to be Back river. Of the bodies on the island, one was supposed to be a chief, as he had a telescope slung about his neck. These men, from all appearances, had been driven to cannibalism before they perished. From the fact that shots were heard, and the feathers of wild fowl were found near the bodies, it is conjectured that a few of the men survived till May, 1851. They seem to have had an abundance of ammunition. There were also numbers of telescopes, guns, watches, &c., pieces of which articles were found among the natives by Dr. Rae, in considerable quantities.

Dr. Rae's opinion was that the party died by starvation, and not by the hands of the natives. Mr. James Anderson was sent out in 1855, to explore more perfectly the spot designated as the scene of so much suffering. On June 30, a little way from the mouth of Back river, he came upon some Esquimaux, who had with them numerous articles belonging to a boat equipage. The natives stated that the owners of these articles had died of starvation. On reaching Montreal island, where the five men had perished, according to report, Mr. Anderson found chain hooks, tools, rope, bunting, and a number of sticks strung together, on one of which was carved the name of Mr. Stanley, surgeon of the Erebus. On a plank was found the word "Terror." Not a vestige of the remains, nor any paper, was found. At Point Ogle some small articles were also found, but no bodies. The party were unable to reach King William land, the scene of the chief disaster.—Dr. Kane, the American explorer, sailed in the Advance from New York, May 30, 1853. The discoveries of Ingfield in Smith strait, and those of Belcher at the head of Wellington channel, had convinced him that there was somewhere between lat. 80° N. and the north pole a vast open sea, and a milder climate than was found some degrees to the south; and further, that in this sea were to be sought, and he hoped found, tidings of Sir John Franklin's long absent expedition. His determination was therefore to penetrate as far up Smith strait as possible, in the hope of being able to enter the polar sea, and there have clear water for his explorations. He entered the ice Aug. 2, and on the 20th found shelter from a hurricane under lee of a rocky island, which he named Godsend ledge. Leaving his men, on the subsidence of the gale, to tow the vessel along the ice, Dr. Kane, Aug. 29, passed ahead with a boating party to explore the coast. He thus passed numerous points of land, and reached Cape George Russell, whence he saw the great glacier of Humboldt, with Cape Jackson on one side, Cape Barrow on the other, and a sea of solid ice between. Not finding on this trip a good place for winter quarters, he returned, and the Advance was moored for the winter in Van Rensselaer harbor, in lat. $78^{\circ} 37'$ and lon. $70^{\circ} 40'$. During the continuance of daylight in the autumn excursions were made into the interior of Greenland, in which over 800 m. were traversed, and the coast was traced for 125 m. to the north and east. Kane's winter harbor is further north than that of any other expedition whatever. The crew were much enfeebled by the long winter, and it was not till April that Kane started on his chief sledging tour to the north. Owing to the severity of the climate and great obstacles, the expedition failed in its main object; but they discovered on this trip some remarkable natural features: the Three Brother Turrets, Tennyson's Monument, and the great glacier of Humboldt. They returned to the vessels May 14. Dr. Hayes and William God-

frey started on another expedition May 20. They crossed Smith strait, and attained to lat. $79^{\circ} 45'$ and lon. $69^{\circ} 12'$. They saw, 30 m. ahead, two capes, which they named Capes Joseph Leidy and John Frazer. On June 30 Messrs. McGary and Bonsall left on a third expedition, Kane being yet ill. They reached Humboldt glacier on the 15th. Four of the party returned on the 24th, entirely blind. Two, Mr. Morton and a companion, pushed on, and on June 21 saw open water to the north, called by them Kennedy channel. They penetrated as far as Cape Constitution in Washington land, lat. $82^{\circ} 27'$. The open channel abounded with animal life, such as bears, birds, and seals. The results of this excursion seemed to Kane to prove that Smith strait in fact opens into Kennedy channel, and this into a great open polar sea, abounding with life. The shores of Kennedy channel and Smith strait had been explored for 760 m. Mr. Morton returned to the ship on July 10. Dr. Kane, seeing no probability of the release of his vessels during this summer, determined to communicate with Belcher's expedition. Failing in this, it was determined that part of the crew should abandon the vessel. The party, however, returned after a few days, and the crew were beset for another winter. It was resolved to abandon the brig in early spring, and make for the Danish settlements at the south. On May 17 they left in boats and sledges, and, after much privation and many narrow escapes, reached Upernavik Aug. 9, in 84 days from the time of leaving the Advance. Fears for Kane's safety had induced the United States navy department to send out in the spring of 1855 two vessels, the Release and the steamer Arctic, to the relief of the missing brig's crew. Capt. Hartstene, who commanded this expedition, reached lat. $78^{\circ} 32'$, and then found his onward progress stopped by a firm barrier of ice. Returning, he found Kane and his crew at Upernavik, and returned with them to the United States in the fall of 1855. In a scientific point of view, Dr. Kane's expedition attained most important results. These are thus summed up by himself in his report to the navy department of the United States:

1. The survey and delineation of the N. coast of Greenland to its termination by a great glacier.
2. The survey of this glacial mass, and its extension northward into the new land named Washington.
3. The discovery of a large channel to the northwest, free from ice, and leading into an open and expanding area, equally free. The whole embraces an iceless area of 4,200 m.
4. The discovery and delineation of a large tract of land, forming the extension northward of the American continent.
5. The completed survey of the American coast to the south and west, as far as Cape Sabine; thus connecting our survey with the last determined position of Captain Inglefield, and completing the circuit of the straits and bay heretofore known at their southernmost opening as Smith sound.

—The *Resolute*, one of Sir E. Belcher's expedition, was, as before mentioned, abandoned May 15, 1854, not far from Beechey island. On Sept. 15, 1855, she was discovered by Capt. Budington, of the *George Henry*, whale ship, of New London, off the W. shore of Baffin bay,

in lat. 67° N. The vessel was encumbered with ice, but was perfectly tight and seaworthy. The distance between the place where she was abandoned and that where she was retaken was at least 1,200 m. She was brought to New London, purchased by the United States government by order of congress, thoroughly refitted, and presented to Queen Victoria and the British government, in December, 1856. The British government took possession of her, and had her stripped and laid up in ordinary in Woolwich dockyard.—In 1857 Lady Franklin, having resolved to send out a vessel at her own expense for a fresh search for her husband, offered the command of the proposed expedition to Capt. Francis McClintock, who had served with distinction in the arctic expedition with Sir James Ross, Capt. Austin, and Sir Edward Belcher. (See McCLINTOCK.) The screw steamer *Fox*, of only 177 tons, formerly the pleasure yacht of Sir Richard Sutton, was purchased, refitted, and equipped with a crew of 24 volunteers. Capt. Allen Young of the merchant service contributed to the cost, and also acted gratuitously as sailing master. Lieut. W. R. Hobson, Dr. David Walker, and Carl Petersen, interpreter, so favorably known as the companion of Dr. Kane, were the principal other members of the party. The little vessel left Aberdeen July 1. McClintock's plan was to examine a tract about 300 m. square lying W. of Boothia, and between the northern limits of the explorations of Rae and Anderson and the southern boundaries of those of Sir James Ross, Austin, and Belcher, while to the west he expected to penetrate as far as the track of Collinson and McClure. Having purchased 35 Esquimaux dogs at Disco, on the coast of Greenland, and taken on board two of the natives as drivers, the *Fox* pushed on toward Lancaster sound until on Aug. 17 she was beset in Baffin bay nearly opposite the entrance to that channel. For eight months the ice held her fast, but the moving pack meanwhile carried her back upon her course, and when finally released, April 25, 1858, she had drifted 1,395 m. to the southward. McClintock refitted at Holsteinborg, arrived in Lancaster sound July 12, sailed through Barrow strait, and attempted to pass down Peel sound, between North Somerset and Prince of Wales land; but having been stopped here by the ice, he passed northeastward around North Somerset in the hope of reaching the mouth of Back river through Bellot strait, which is the water communication between Prince Regent inlet and the western sea (now known as Franklin strait), and separates the North American continent from North Somerset. He found the strait obstructed by moving ice, but after much difficulty and danger pushed through it on Sept. 6. A frozen barrier stretched across its western end, and here the *Fox* remained moored for three weeks, when she took up her winter quarters at Port Kennedy, on the N. shore of the strait. In the mean time extensive sledge

journeys were undertaken. Lieut. Hobson carried out provisions toward the magnetic pole. Capt. Young established a depot on the further side of Franklin strait, and McClintock and Petersen travelled southward in the hope of gathering some information from the natives. On March 1, 1859, McClintock met a party of Esquimaux near Cape Victoria, and learned from them that several years before a ship had been crushed in the ice and sunk in deep water off the N. W. shore of King William land. Her people went away to a great river, where they all died of starvation, and their bodies were found the next year. It was impossible to obtain any information respecting the number of white men, or the length of time since they left the ship. Another interview with some of the natives in April confirmed these statements, and threw light upon the fate of Franklin's second vessel, which they said drifted ashore at King William land. The skeleton of one man was found on board. Sending Hobson to search for the wreck, McClintock explored the E. shore of King William land, and on May 7 came upon a village of Esquimaux, from whom he learned that when the white people marched toward the great river "many of them dropped by the way," and their bodies were found the next winter; some were buried and others were not. Point Ogle, Montreal island in the estuary of Back river, and Barrow inlet were searched, with no better success than the discovery of a few scraps of iron, tin, and copper; and McClintock, having now reached the track of Anderson and Stuart (1855), resolved to follow the S. and W. coasts of King William land until he met Hobson. The first trace of the long lost crew was found near Cape Herschel, the western limit of Simpson's explorations. It was a bleached skeleton lying at full length on the beach; fragments of European clothing, a pocketbook, and a few letters were picked up about it. A day's march N. E. of Cape Crozier the party came across a boat fitted to a sledge and apparently prepared for navigating the river. In it were two skeletons, two loaded guns, and various other relics, including Sir John Franklin's silver plate, besides fuel, ammunition, chocolate, tea, and tobacco. Its head was turned toward the abandoned ships, from whose first position it was about 65 m. distant. A record was also found which had been left here five days before by Hobson, who in the mean time had made still more interesting discoveries. After separating from McClintock he had tracked the N. and W. shores of King William land almost to Cape Herschel. Near Cape Felix, the northernmost point of the island, he found a ruined cairn, three tents, and other traces of Franklin's party, but no record; two smaller cairns were afterward examined, and on May 6 a large one was observed at Point Victory, where Sir James Ross had touched in 1830. Lying among some stones which had fallen from the top of the

structure was a tin case enclosing a record, the first authentic account ever obtained of the history of the lost expedition. It was written on one of the printed forms used in discovery ships for the purpose of being enclosed in bottles and thrown overboard in order to ascertain the direction of the currents. It read as follows:

25. of May, 1847.—II. M. ships Erebus and Terror. Wintered in the ice in lat. 50° 5' N., lon. 95° 22' W. Having wintered in 1846-'7 at Beechey island in lat. 74° 43' 28" N., lon. 91° 30' 15" W., after having ascended Wellington channel to lat. 77° and returned by the W. side of Cornwallis island. Sir John Franklin commanding the expedition. All well. Party consisting of 2 officers and 6 men left the ships on Monday, 24th May, 1847. Wm. Gore, Lieut.; Chas. F. Des Vieux, Mate.

Around the margin was written in a different hand:

April 25, 1848.—II. M. ships Terror and Erebus were deserted on the 22d April, 5 leagues N. N. W. of this, having been beset since 12th Sept. 1846. The officers and crews, consisting of 105 souls, under the command of Captain F. R. M. Crozier, landed here—in lat. 69° 37' 42", lon. 98° 4' 15". This paper was found by Lt. Irving under the cairn supposed to have been built by Sir James Ross in 1831, 4 miles to the northward, where it had been deposited by the late Commander Gore in June, 1847. Sir James Ross's pillar has not however been found, and the paper has been transferred to this position, which is that in which Sir J. Ross's pillar was erected. Sir John Franklin died on the 11th June, 1847, and the total loss by deaths in the expedition has been to this date 9 officers and 15 men.*

JAMES FITZJAMES, Captain
F. R. M. CROZIER,
Captain and senior off.
and start on to-morrow, 26th,
for Back's Fish river.

H. M. S. Erebus.

The date 1846-'7 given as that of Franklin's wintering at Beechey island is evidently an error; it should be 1845-'6. Vast quantities of clothing and other articles were found here. The wreck was not seen, nor were any more skeletons found; but this indeed was hardly to have been expected, as the route toward Back river was almost all the way over ice which breaks up in summer. Meeting no more of the Esquimaux nor further traces of the lost voyagers, and feeling certain that the whole expedition had perished, McClintock returned to his vessel, June 19, carrying a great number of relics, many of which had been purchased from the natives. Besides solving the problem which had engaged arctic enterprise for 11 years, his expedition had completed the delineation of the N. shore of the American continent; laid down the previously unknown outline of Boothia and the coast of King William land; proved the navigability of Bellot strait, the existence of which was before doubted; opened a new and capacious channel extending N. W. from Victoria strait to Parry or Melville sound, and since named at the suggestion of Lady Franklin McClintock channel; observed many interesting facts in terrestrial magnetism; and finally, proved Sir John Franklin to be the discoverer of the northwest passage. With the aid of McClintock's narrative we are now able

* These figures make the original force of Franklin's expedition 129, whereas it has commonly been stated at 138. It has been ascertained, however, that only 134 actually left England, and 5 of these returned.

to trace out Franklin's last voyage. During the first season it was unusually prosperous. Passing up Lancaster sound, he explored Wellington channel (then an unknown sea) to a point further N. than was reached by either Penny, De Haven, or Belcher; sailed around Cornwallis island, and wintered at Beechey island. In the spring and summer of 1846 he either navigated Bellot strait, or more probably pushed through Peel sound, reaching Victoria strait, where he was finally beset in September, and thus supplied the only link wanting to complete a chain of water communication between the two oceans. The skeletons found in the boat near Cape Crozier show that after the abandonment of the Erebus and Terror a party attempted to return, for what purpose can only be conjectured. The Fox found herself free from ice on Aug. 9, and immediately made sail for home, reaching the Isle of Wight Sept. 20. See McClintock's "Narrative of the Discovery of the Fate of Sir John Franklin and his Companions" (London and Boston, 1860); also "The Search for Sir John Franklin," in the "Cornhill Magazine," No. 1, January, 1860 (by Capt. Allen Young).—Dr. Isaac I. Hayes, a member of Kane's party, and a firm believer in the theory of the open polar sea, soon succeeded, with the aid of private subscriptions, in organizing and fitting out another arctic exploring expedition. With a company of only 14 men, he left Boston July 6, 1860, in the schooner United States, and proceeded directly to the Greenland ports of Pröven and Upernavik; at the latter place he arrived Aug. 12, and besides adding to his crew three Danes and three Esquimaux hunters, he secured sledge dogs for the winter's work. Carruthers, one of the schooner's crew, died at Upernavik. Leaving port, Dr. Hayes's expedition entered Baffin bay about Aug. 20, but was so delayed by ice, among which the schooner was often becalmed, that although the party had hoped to reach some point between lat. 79° and 80°, the schooner was frozen in at a point but little N. of lat. 78°, in a harbor which Hayes named Port Foulke. During the winter Dr. Hayes made several sledge expeditions, but attained no important results until April 3, when, with several sledges drawn by dogs, a life boat upon another sledge drawn by men, and 12 of the ship's company, he started from Port Foulke to cross Smith sound to Grinnell land; for along the coast of this Hayes had determined to proceed, all progress along the E. shore of the sound being prevented by impassable glaciers. After encountering difficulties of every kind, and after sending back nearly all of the party and several sledges, with the life boat, which could be carried no further, Hayes and three of his men succeeded (May 11) in reaching Grinnell land at a point called Cape Hawks. They immediately turned to the north, and for several days skirted the coast, travelling on smoother ice and with less danger than before. But Hayes's

companions were greatly exhausted, and he was finally compelled to leave two of them. On May 18, 1861, Dr. Hayes and his remaining companion, Knorr, who had been travelling among soft ice for several days, reached a point (lat. 81° 35', lon. 70° 30') beyond which further progress was impossible on account of rotten ice and cracks. This was the most northerly land ever reached; and, climbing a headland, Hayes found himself standing upon what he believed to be the shores of the polar sea, which, though then encumbered with soft ice and floes, would, he felt confident, be entirely open in the summer months. To the north he saw a lofty headland, "the most northern known land upon the globe." Having no boat, Hayes was obliged to turn back; rejoining all his companions, he reached the schooner about the 1st of June, after a wearisome journey. Without making further important explorations, for which the schooner had been unfitted by injuries from the ice and storms, the expedition returned successfully to Boston in October, 1861. The civil war had broken out, and this led Dr. Hayes to at once abandon the project he had formed of returning immediately with a steamer to the arctic seas. In his story of the voyage ("The Open Polar Sea," New York, 1867), he declared that he had by no means given up the ultimate accomplishment of his plan.—In 1860 Capt. Charles F. Hall, who had for more than ten years been deeply interested in arctic discovery, left New London, Conn., in a whale ship, which, in pursuance of his plan, landed him on the W. coast of Davis strait, whence he intended, with boat and sledge, to make further search for evidences of the fate of Sir John Franklin and his men. He lost his boat, and was obliged to confine his explorations within comparatively narrow limits. He made, however, an important discovery—some traces of the expedition under Frobisher, 300 years before. On Sept. 30 Hall returned. In 1864 he again sailed for the arctic countries, landing, with only two Esquimaux as companions, on the coast of Hudson bay. He penetrated to the north as far as Fury and Hecla strait, journeyed into King William land, and met with much success. Besides bringing home many actual relics of Franklin's party, he succeeded in obtaining such exact information from the Esquimaux at various points as led him to suppose that Franklin had actually accomplished the discovery of the northwest passage before his vessels, then in winter quarters (at O'Reilly island, Capt. Hall believes), were abandoned by their crews. Hall seems to have finally established, by the universal testimony of the tribes he visited, the truth of the Esquimaux story that Franklin's men died of starvation in King William land. He did not, however, succeed in finding any records of the expedition. After spending five successive years among the Esquimaux, passing much of the time near Repulse bay, and after acquiring a thorough knowledge of their language and cus-

toms, Capt. Hall returned in September, 1869, to the United States, where he applied himself to the organization of a new expedition.—A German arctic expedition, organized by Dr. Petermann of Gotha, and placed under the command of Capt. Koldewey, left Bremen in the spring of 1868, in the *Greenland*, a vessel of 80 tons burden. Leaving Bergen, Norway, in May, Koldewey succeeded in reaching a point in lat. $81^{\circ} 5' N.$, lon. $16^{\circ} W.$ He returned in October to Bremen. In 1868 the Swedish government also sent out an expedition, which sailed to the north of Spitzbergen, but without any noteworthy discoveries.—In 1869 Dr. Hayes visited Upernavik to make preparations for the expedition he had not ceased to plan; he then hoped to undertake it during the year 1870. In a small steamer, the *Panther*, Dr. Hayes and his party made a short voyage about the arctic seas, but did not prosecute any extensive explorations.—On June 15, 1869, another German expedition left Bremen; the vessels were the *Germania*, under Capt. Hege- mann, and the *Hansa*, under Capt. Koldewey. Through a mistake in the reading of signals, the two vessels parted in July, the *Germania* following the E. coast of Greenland, and wintering in Sabine bay; while the *Hansa* was wrecked in October among the ice along the shore. Her crew took refuge on a field of moving ice, which, as it floated southward, gradually diminished, until, after it had become a mere raft, they were obliged to take to their three boats, by means of which they finally reached Friedrichsthal, near Cape Farewell. They reached home in the summer of 1870. Meanwhile the *Germania* had endeavored, but without success, to reach high latitudes by following the E. coast of Greenland; and in the autumn she also returned to Bremen. Though the voyage contributed much to scientific knowledge, no new discoveries of importance were made by either of the crews. Several other expeditions were sent out from the continent of Europe in 1869, but they accomplished little beyond scientific research, conducted in regions already known.—Still less was done in 1870. Capt. Sherard Osborn, of the British navy, had for several years urged a new expedition by way of Smith sound in search of the open polar sea, but his views were not sustained by the board of admiralty, and he failed to secure aid from the government. A French scheme for arctic exploration was abandoned on account of the war with Germany.—In 1871 several arctic voyages were begun. In the summer James Lamont, an Englishman, sailed to the eastward of Greenland, but made no new discoveries. In June the Austrian lieutenants Payer and Weyprecht, in a small Norwegian sailing vessel, sailed from Tromsø, Norway, into the Arctic sea to the north of Nova Zembla, where they succeeded in discovering an open ocean in which navigation was only impeded by very light and scattered ice. In October they returned to Tromsø,

having penetrated to lat. $78^{\circ} 41' N.$ Dr. Petermann, the German geographer, looks upon the discoveries made by this unpretending expedition as most important, as he believes that Payer and Weyprecht actually penetrated into the open polar sea, and found the entrance of the best, if not the only water passage to the neighborhood of the pole. Their discoveries seem also to confirm the theory originally advanced by Capt. Silas Bent of the U. S. navy, that the pole can best be reached by following the course of the Gulf stream northward between Spitzbergen and Nova Zembla; it is claimed by the supporters of this theory that the warmer water of the great current not only keeps the northern channel free from ice at this point, but is the cause of the open polar sea. An expedition fitted out by A. Rosenthal of Bremerhaven began in 1871 the exploration of the ocean N. of Siberia. The Norwegian captains Tobiesen and Mack confirmed the discovery of Payer and Weyprecht. Another Norwegian, Capt. Carlsen, discovered the remains of the winter quarters established 275 years before at the N. E. end of Nova Zembla by the Dutch captain Barentz. Ulve and Smyth sailed to the north of Spitzbergen and found open water even in lat. $80^{\circ} 27'$. Finally, Capt. Hall organized at last, with the aid of congress, his long desired American expedition toward the pole; and on June 29 he sailed from New York with a well selected corps of assistants and crew, in the wooden steamer *Polaris*, of about 400 tons. For nearly two years no important news was received from the explorers. On April 29, 1873, the British steamship *Tigress* struck an ice floe in lat. $53^{\circ} 35' N.$, lon. $35^{\circ} W.$ On this floe were found Capt. Tyson, one of Hall's officers, and 18 others, who had been 196 days on the ice, and drifted about 2,000 miles. They reported that on Oct. 15, 1872, the *Polaris* being fast in the ice about lat. $77^{\circ} 35'$, and leaking badly, they had been ordered to land provisions; and that while so engaged the floe broke up, and they were separated from the ship and rapidly drifted southward, without seeing her again. Their report gave the following details of the expedition. Capt. Hall sailed up Kennedy channel and through a strait which he named Robeson, and on Aug. 24, 1871, reached lat. $82^{\circ} 16' N.$ It being deemed prudent to fall back, the *Polaris* was taken on Sept. 5 into winter quarters in Thank God bay, lat. $81^{\circ} 38' N.$ On Oct. 10 Capt. Hall started on a sledge expedition, but did not go beyond lat. 82° . On his return he was taken suddenly ill, and died on Nov. 8. The command then devolved on Capt. Buddington, who resolved to return, and on Aug. 12, 1872, the *Polaris* was turned southward. She drifted with the ice into Baffin bay, where Tyson left her.

ARCTURUS (Gr. *ἄρκτος*, bear, and *οὔρος*, guard, or *οὔρα*, tail), formerly a constellation near the Great Bear. Later the name was confined to the largest star in the constellation, which was after-

ward called Boötes. It is a star of the first magnitude, and was at one time erroneously believed to be the star nearest to our system.

ARCUEIL, a village of France, department of Seine, on the Bièvre, $3\frac{1}{2}$ m. S. of Paris; pop. in 1866, 5,024. It is celebrated for an aqueduct constructed there by the Roman emperor Julian during his abode in Paris, to convey water from the Bièvre to his palace. Remains of this are still seen near the modern aqueduct, constructed by Maria de' Medici in 1618, to bring water to supply the gardens and the palace of the Luxembourg and the fountains of Paris. Arcueil was for a long time the residence of the chemist Berthollet, whose friends, meeting here for scientific study under the name of *société d'Arcueil*, published several volumes of memoirs. The house of Berthollet is now a college of that branch of the Dominican order founded by Lacordaire.

ARCY, *Grotto of*, a vast and beautiful stalactitic cavern, which consists of many compartments, near Vermenton, department of Yonne, in France, 12 m. S. S. E. of Auxerre. The hill in which this remarkable cavern exists stretches into the valley of the river Cure. One of the compartments of the grotto is 1,200 feet long, 85 high, and 40 wide. In the first two compartments are found large blocks of stone, and in the second compartment is a spring of good water. In the other chambers stalactites hang from the roof, while stalagmites rise column-like from the ground. The caverns are supposed to have been quarries in former times, but have been abandoned so long that every trace of human labor is obliterated. It is said that the stone with which the cathedral of Auxerre was built was taken from the grotto of Arcy.

ARDABIL, *Ardebil*, or *Erdebil*, a town of Persia, in the province of Azerbaijan, 110 m. E. of Tabriz, and 35 m. W. of the Caspian, situated 5,000 feet above the sea, at the foot of the Salavan mountains; pop. about 4,000. A fine and fertile situation has made it a favorite resort of Persian princes. Abbas Mirza had a fort built there as a protection against the Russians, who were for some time in possession of the town during the war of 1826-'8. It was flourishing in former centuries under the Sufites, whose founder as well as the first shah of that dynasty are buried here in a beautiful mausoleum which is a resort of pilgrims. The town has been devastated by earthquakes and is in decay, though still retaining some commercial importance.

ARDECHE, a S. E. department of France, bounded E. by the Rhône; area, 2,134 sq. m.; pop. in 1872, 380,277. The river Ardèche, from which it has its name, rises near its centre and flows S. S. E. to the Rhône. The Loire has its source near that of the Ardèche, and flows in the opposite direction. A large portion of the surface is occupied by branches of the Cévennes mountains. The department is rich in iron and coal, but deficient in agricultural pro-

ducts, though potatoes are largely raised, chestnuts are plentiful in the forests, and the pasturage is fine. Wine, silk, and wool are among the principal exports, as well as various manufactured goods, including famous stationery. Privas is the capital, and the other chief towns are Annonay and Aubenas. The department is divided into the three arrondissements of Privas, Largentière, and Tournon.

ARDENNES, a N. E. department of France, bounded N. by Belgium; area, 2,021 sq. m.; pop. in 1872, 320,217. The forest of the Ardennes, an elevated wooded tract, from which it is named, begins in its N. part, thence spreading in various branches, but chiefly along the Meuse and Sambre, over the Belgian provinces of Namur, Hainault, and Liège, and over Luxembourg. The department is also traversed, mainly in the east and centre, by ridges and offshoots of the Argennes. The principal rivers are the Meuse and the Aisne. The valley of the latter is remarkable for its large crops, and there are other very fertile valleys. Among the sheep are several long-wooled and merino breeds; the horses are fine, and game abounds. There are iron, lead, calamine, and coal mines, and important slate and marble quarries. Nails and other iron wares, earthenware, glass, leather, woollens, firearms, and other articles are manufactured. Timber is the fuel used in the iron and copper works, besides being exported. The capital is Mézières. Sedan is the chief place for the manufacture of cloth, and Charleville for the iron trade. The department is divided into the arrondissements of Mézières, Roeroy, Rethel, Vouziers, and Sedan.

ARDESHIR, *Ardshir*, or *Artaxerxes*, *Babegan*, founder of the Persian dynasty of the Sassanides in A. D. 226, died about 240. According to a critical opinion not fully established, he was the son of Babek, son of Sassan, a shepherd, who claimed descent from the line of the ancient Persian kings; and the son gradually gained an importance which brought upon him the enmity of Artaban, the last ruler of the Parthian empire. Ardeshir then announced his intention to recover the throne of his ancestors and to exterminate the Arsacide usurpers. He gave battle to Artaban, whom he vanquished and put to death, and caused himself to be proclaimed *shahan shah*, "king of kings." He rapidly recovered the provinces constituting the old Persian empire, and even extended its limits. A war with the Romans was of short duration. During the years of profound repose which marked the latter part of his reign, he cultivated the arts of peace, and as a jurist and legislator showed remarkable capacity. His principal achievement at home was the restoration of the pure Zoroastrian religion.

ARDITI, *Luigi*, an Italian violinist and composer, born at Crescentino in Piedmont, July 22, 1822. He received his musical education in the conservatory at Milan, and first made himself known in public concerts as a violinist in 1839. In 1841 his opera *I Briganti*

was produced at Milan. In 1851 he visited Havana and the United States, and was for several seasons conductor at the Italian opera houses in New York. While in that city he composed an opera entitled *La Spia*, the plot of which was based upon incidents in Cooper's novel "The Spy." To identify it as an American work, "Hail Columbia" was introduced as the finale. The opera was brought out at the New York academy of music March 24, 1856, but its merits did not entitle it to any great success. Shortly after this production Arditi went to London, where he became the leader of the opera at her majesty's theatre. His songs have met with a greater popularity than his more ambitious compositions.

ARE (from Lat. *area*, a broad piece of level ground), the unit of surface in the French system of measures, equivalent to a square decamètre, or 1,076.44 English square feet. Parts of an are are expressed by Latin prefixes, déciare, centiare, &c., signifying one tenth, one hundredth, &c., of an are. Multiples of an are have Greek prefixes, décare, hectare, &c., signifying ten, one hundred, &c., ares.

ARENDAL, a town of S. E. Norway, on a river of the same name, in the province and 40 m. N. E. of Christiansand; pop. in 1865, 7,181. It is built on piles and islands, and has been called "Little Venice" on account of its canals and picturesque appearance. The harbor is protected by the opposite island of Tromø, and there is an active trade in iron and timber.

AREGLAR TISSUE. See CELLULAR TISSUE.

AREOMETER. See HYDROMETER.

AREOPAGUS, the hill (Gr. *πάρος*) of Ares or Mars, a craggy eminence in ancient Athens, not far from the Acropolis, famous as the spot where the celebrated council or court of the same name held its sittings. This body was, above all similar courts of Greece, distinguished by its great antiquity and high character. Its origin is carried back by ancient writers as far as the time of Cærops; but Solon is supposed to have framed, or at least greatly modified, the historical constitution of the Areopagus, and to have extended its functions, so that from being merely a criminal tribunal, its jurisdiction reached the general morals of society and the political affairs of the state—touched everything, in fact, which concerned the public weal. It is not known of how many members the Areopagus was composed, and possibly the number was unlimited, the members serving for life, and consisting of ex-archons of unspotted character. Pericles is said to have deprived it of a portion of its prerogatives, and later its members were made responsible to the people. Its fame was alive in the time of Cicero, and even as late as the emperor Theodosius. In the records of Christendom the hill of Mars is memorable as the spot where the apostle Paul commenced the delivery of a discourse, the outline of which is preserved in the book of Acts. There is no intimation that Paul was brought before the council of the Areopagus.

AREQUIPA. I. A S. department of Peru, bounded S. W. by the Pacific; area, about 45,000 sq. m.; pop. about 200,000. It is divided into the provinces of Arequipa, Islay, Castella, Camaná, Union, Condesuyos, and Cañlloma. The eastern section is a high table land belonging to the Andes region; the rest lies between the main range of the Andes and the Pacific. The mountains are for the most part covered with perpetual snow, from which rises the volcano of Misti or Arequipa to a height of about 20,000 ft. The western section is very fertile, and is watered by the Ocoña, Camaná, and other rivers, all of which flow to the Pacific. By reason of the diversity of elevation, almost every known vegetable product of the earth is raised. Oil, wine, and brandy of good quality are made, and the fruits of the department have earned for it the title of the garden of Peru. The western portion is covered with cattle, sheep, and goats, while the mountains

Volcano of Misti or Arequipa.

and plateaux abound with llamas, alpacas, guanacos, vicuñas, and other wool-bearing quadrupeds. Silver, copper, tin, lead, sulphur, rock crystal, and coal are found. Earthquakes are very frequent and disastrous, and are invariably accompanied by eruptions of the volcanoes of Misti, Omate, Tutupaca, and Ubinas. II. A town, capital of the preceding department, situated 7,850 feet above the sea, on the river Chili, 40 m. from the coast, in lat. $16^{\circ} 30' S.$, lon. $72^{\circ} 20' W.$, 480 m. S. W. of Lima, in the midst of a fertile district and near several gold and silver mines; pop. about 35,000. It was one of the best built towns in South America, having a cathedral and several other churches, 9 convents, a college, a hospital, and houses of stone solidly constructed and vaulted; but it was almost wholly destroyed by the earthquake of Aug. 13-15, 1868, in which nearly every house was levelled with the ground and 600 persons were killed. A similar disaster had

happened to the city on four previous occasions. Its ancient site was two leagues E. of the present one; the removal was made after Arequipa had been nearly buried in ashes from the volcano of Misti in the 16th century.

ARES. See **MARS**.

ARETEUS, a Greek physician of Cappadocia, flourished about A. D. 100. His contemporaries rank him next to Hippocrates. He wrote a comprehensive treatise, in eight books, on acute and chronic diseases, which is still extant, and was published by Wigan (Oxford, 1723) and by Kühn (Leipsic, 1828).

ARETHUSA, a fountain in the island of Ortygia, which formed a part of the ancient Syracuse, in Sicily. The ancients supposed its waters to be united with those of the river Alpheus in Peloponnesus. The naiad of the fountain was the nereid Arethusa. (See **ALPHEUS**.)—Another Arethusa was one of the Hesperides, the guardians of the golden apples, to obtain which was one of the 12 labors of Hercules.

ARETINO. **I.** Guido, or Guido d'Arezzo, a Benedictine monk, born at Arezzo near the end of the 10th century. He early occupied himself in devising new methods of writing and teaching music. Instead of a group of tetrachords like the Greek method, or of heptachords such as Gregory adopted, he proposed a new system, consisting of hexachords. The six syllables by which he designated his notes were suggested to him, it is said, by a Latin hymn to St. John:

UT queant laxis *RE*sonare fibris
*MI*ra gestorum *FA*muli tuorum,
*SOL*ve polluti *LA*bii reatum,
Sancte Johannes.

To the seventh note, *si*, he gave no name, and for a long time it continued to be called *b*. Guido's new method of solmization attracted much attention. Whereas ten years had been required to learn to read music, a chant could be mastered by this method in a few days, and a year sufficed to make a skilful singer. Pope John XVIII. (1024-'33) invited Guido to his court and was greatly pleased with his plan. Guido not only facilitated the reading of music, but simplified the manner of writing it. Since St. Gregory, attempts had been made to improve musical notation. Already the seven letters, formerly written on one line, were placed on parallel lines, to indicate the rising and falling of the voice. Guido, instead of repeating the letter, wrote it at the beginning of the line, and each time it occurred marked a point on the line. He ended by placing the points within the lines, thus rendering the written composition more compact. Guido has the fame of being the inventor of the modern gamut. **II.** See **BRUNI**, **LEONARDO**. **III.** Pietro, an Italian writer, born in Arezzo in 1492, died in Venice in 1557. He was the natural son of a gentleman named Luigi Bacci, and was brought up by his mother, Tita. While still very young he was obliged to leave his native city on account of having written a sonnet against indulgences, and went to Perugia, where

for a long time he supported himself as a book-binder. Thence he went on foot to Rome, and obtained employment in the service of Popes Leo X. and Clement VII.; but, having composed 16 sonnets for as many licentious designs of Giulio Romano, he was forced to retire to Arezzo (1524), and soon afterward to the court of Giovanni de' Medici. At length he returned to Rome, where he made love to a cook, and composed a sonnet in her praise. A Bolognese gentleman, Achille della Volta, was a rival lover, and finding Aretino one day alone, stabbed him five times in the breast and maimed his hands (1525). Displeased with the refusal of the pope to punish his assailant, Aretino sought once more the court of Giovanni de' Medici. This prince having been killed in battle in 1526, Aretino resolved to have no more protectors, but to support himself by his pen. With this view he went to Venice in 1527, where he chiefly passed the rest of his life, becoming reconciled with the pope in 1530. His end was peculiar. Having heard of some excesses of his sisters, he found them so comical that he threw himself back in his chair laughing, fell over backward, and was killed.

AREZZO. **I.** A province of Italy, in Tuscany; area, 1,276 sq. m.; pop. in 1872, 239,901. It is watered by the Arno, and includes the valley of the Chiana, 20 m. long, formerly a vast and pestilential marsh, but which has been drained within the last century and converted into about 40 sq. m. of the most fertile land of Italy and perhaps of Europe. Arezzo is famous for its wines, corn, oil, and fruits. Among the towns of this province are Cortona and Montepulciano. **II.** A city (anc. *Arretium* or *Arctium*), capital of the preceding province, situated in a fertile valley, near the confluence of the Chiana and Arno, about 36 m. S. E. of Florence; pop. 38,907. In antiquity it was one of the principal states of Etruria. Its extensive walls are undoubtedly Etruscan, and were of importance to the Romans as a barrier against the Cisalpine Gauls. It was celebrated for its terra-cotta vases, ranked by Pliny with those of Samos and Saguntum. During the contest of the Guelphs and Ghibellines, Arezzo, then a very populous city, fought against Florence, but was finally obliged to yield. Among the public buildings are the magnificent Loggie, by Vasari, the cathedral and several beautiful churches, the Museo Bacci, and the Palazzo Publico, which has upon its front a curious series of the armorial bearings of the successive podestas, amounting to several hundreds. It is the birthplace of a number of distinguished men, hence known by the surname of Aretino, as well as of Petrarch, Vasari, and others.

ARGEUS, Mount. See **ARMISH**.

ARGALL. See **SHEEP**.

ARGALL, Samuel, one of the early adventurers to Virginia, born in Bristol, England, in 1572, died in 1639. His first public exploit was the abduction of Pocahontas, in 1612, from the

care of a chief who had been intrusted by Powhatan with the charge of his daughter, but who surrendered her for the bribe of a brass kettle. Taking her to Jamestown, he gave her to the governor, Lord Delaware. In 1617 he became deputy governor of Virginia, in which office he demeaned himself so tyrannically that he was recalled in 1619, returning to England with immense wealth. Under the governorship of Sir Thomas Dale he commanded an expedition which sailed in 1613 to Port Royal in Nova Scotia, which place he reduced and plundered, driving the French colonists into the woods. He also destroyed the French settlement of St. Saviour on Mount Desert island. It has been stated that on his return to Virginia he appeared before New Amsterdam, and summoned the Hollanders to surrender their territory on the ground that Henry Hudson, its discoverer, was an Englishman; but Brodhead, in his "History of New York," arrives at the conclusion that the whole story is fabulous. After the death of Lord Delaware, Argall took charge of his estate, and letters of Lady Delaware now in existence accuse him of the most flagrant peculation.

ARGELANDER, Friedrich Wilhelm August, a German astronomer, born at Memel, March 22, 1799. He attended the university of Königsberg, where he at first devoted himself to political science. His attention was turned toward the study of astronomy by the lectures of Bessel, and in 1821 he was made his assistant in the observatory. In 1822 he was appointed an instructor in the university. In the same year he published his *Untersuchungen über die Bahn des grossen Kometen von 1811*, establishing the length of the comet's period as 2,840 years. In 1823 he was made chief of a new observatory at Abo, where he passed several years, publishing in 1830 and 1832 the results of his observations in 560 different cases (*Observationes Astronomice Aboe facta*, 3 vols., Helsingfors), and in 1835 the determination of the positions of the stars he had observed (*DLX Stellarum Fixarum Positiones Medie*). In 1837 appeared his great work, *Ueber die eigene Bewegung des Sonnensystems* (St. Petersburg), in which he proved the truth of Herschel's theory concerning the independent movement of the solar system. In 1832 he had been appointed a professor at the university of Helsingfors, and after superintending the building of an observatory, which was completed about the time of the publication of his last-mentioned work, he accepted a professorship at Bonn. Here also he took charge of the building of a new observatory, and completed it in 1845. He published in 1846 *Durchmusterung des nördlichen Himmels zwischen 45° and 80° nördlicher Breite* (Bonn). His other noteworthy works are: *Neue Uranographie* (Berlin, 1843); *Atlas des nördlichen gestirnten Himmels* (Bonn, 1857); and a catalogue of more than 216,000 stars, printed in the third and fourth volumes of the *Astronomische Beobachtungen auf der*

Sternkarte zu Bonn. He was chosen a member of the French institute in 1850. Within the last ten years he has devoted himself to observations of variable stars.

ARGENS, Jean Baptiste de Boyer, marquis d', a French writer, born in Aix, June 24, 1704, died in Toulon, June 11, 1771. He entered the army, but in consequence of an escapade with an actress his relatives procured his appointment as secretary of legation to the French embassy at Constantinople. On his return from Turkey he again joined the army; but during the siege of Kehl he was wounded, and soon after a fall from his horse disabled him for military service. As his father had disinherited him, he took to literature to support himself; and availing himself of the liberty of the press in Holland, he published there his *Lettres juives*, *Lettres chinoises*, and *Lettres cabalistiques*, each in several volumes. These attracted the attention of the crown prince of Prussia, the future Frederick the Great, who wished him to come to Berlin; but D'Argens would not go, because, as he wrote in apology, he was afraid that his tall figure would tempt King Frederick William to enroll him in his army. However, after the accession of Frederick the marquis went to Potsdam, was appointed director of fine arts in the academy of Berlin, and was on the best of terms with the king until he married an actress without asking the royal consent. He then returned to France, where he remained till his death. His most important work is his *Histoire de l'esprit humain*.

ARGENSON, Voyer d', a distinguished French family of Touraine. **I. René Louis**, marquis d', born Oct. 18, 1694, died Jan. 10, 1757. In 1741 Louis XV. appointed him minister of foreign affairs, and he held this office till 1747, when the intrigues of Spain, whose policy he had frustrated in his negotiations with Italy, brought about his resignation. From that time he devoted himself principally to literature, and wrote, besides essays, *Considérations sur le gouvernement de la France*. **II. Marc Pierre**, count d', brother of the preceding, born Aug. 18, 1696, died in Paris, Aug. 22, 1764. He was for some time secretary of the war department under Louis XV., and in this capacity did much for France during the war which preceded and the peace which followed the treaty of Aix-la-Chapelle, in 1748. D'Alembert and Diderot dedicated to him their *Encyclopædia*, begun during his ministry, and he furnished Voltaire with valuable materials for his *Siècle de Louis XIV.* **III. Marc Antoine René de Palmy**, son of René Louis, born in 1722, died in 1787. He was ambassador in Switzerland, Poland, and Venice, but, disappointed in obtaining the Roman mission, he resigned his public offices and devoted himself to literary pursuits. He edited 40 volumes of the *Bibliothèque universelle des romans*, including some of his own novels. He was elected a member of the French academy, and appointed governor of the arsenal, and distinguished himself by the splendid col-

lection of 150,000 volumes with which he endowed his library. **IV. Marc René**, grandson of René Louis, born in Paris, Sept. 10, 1771, died there, Aug. 2, 1842. He served for a time as adjutant of Gen. Lafayette. In 1809 he became prefect of the department of Deux-Nèthes (now province of Antwerp, Belgium), but relinquished his place on account of a disagreement with the ministry, caused by D'Argenson's refusal to sequester the property of the mayor of Antwerp. He took an active part in the expulsion of the English from Walcheren. During the hundred days he was a member of the house of representatives for Belfort, and belonged to the deputation who besought the allied forces to prevent the return of the Bourbons. He was reelected as deputy after the second restoration, and distinguished himself by his eloquent denunciation of the massacre of the Protestants in the south of France. In 1830 he reentered the chamber of deputies as member for Strasburg, and created a great sensation by taking his parliamentary oath with the words *Je le jure, sauf les progrès de la raison publique*. In May, 1832, he was one of the opposition members who signed the famous *Compte rendu*, and in October, 1833, he signed the manifesto of the *société des droits de l'homme*. He was one of the chief leaders of the secret society *charbonnerie démocratique*, and was designated as the future dictator of France in case of a revolution.

ARGENTAN, a town of France, in the department of Orne, in Normandy, situated on the river Orne, 22 m. N. by W. of Alençon; pop. in 1866, 5,401. It is finely situated on a hill in the midst of fertile plains; and the ramparts and ditches have been converted into promenades. There are two large Gothic churches and a college. Formerly the town was famous for its laces (*point d'Argentan* and *point d'Alençon*), but the chief industry consists at present in manufacturing gloves, leather, and embroidery, and in exporting cattle and cheese.

ARGENTEUIL, a town of France, in the department of Seine-et-Oise, on the Seine, 5 m. N. W. of Paris; pop. in 1866, 8,176. It carries on an active trade in wine of inferior quality. Among the adjoining country seats is the château du Marais, formerly owned by Mirabeau. The town originated from the convent or priory of Argenteuil founded in the 7th century, and converted by Charlemagne into a nunnery, of which Héloïse became abbess, after having been educated and taken vows there. Its ruins are still extant.

ARGENTEUIL, a W. county of the province of Quebec, Canada, bounded S. by the Ottawa river; area, 850 sq. m.; pop. in 1871, 12,806. The soil is in many parts of exceptionally good quality. There is a quarry of French buhrstone in Grenville township. Capital, Lachute.

ARGENTUS CODEX, an old uncial MS. of the four gospels in the Mæso-Gothic dialect, written or stamped in silver letters (except the initials, which are in gold) on violet-colored vellum.

It is supposed to have been executed about the 6th century, and is a copy of the version made in the 4th by Ulfilas, the Arian bishop of the Mæso-Goths. This codex was discovered in the library of the Benedictine abbey of Werden in 1597, and after changing hands, either honestly or by stealth, several times, came at length into the possession of the library of Upsal for the consideration of about \$1,250. Facsimile editions of some portions of it have been published by Knittel, and also by Angelo Mai (1819). Mai also discovered some palimpsests of this version in the Ambrosian library, which have been published. These more recent discoveries have aided to fill the chasms in the Argenteus Codex, and so to enhance its value to Biblical literature.

ARGENTINE REPUBLIC (*La República Argentina*; formerly more commonly called ARGENTINE CONFEDERATION), an independent state of South America, between lat. 21° and 41° S., and lon. 53° and 71° 17' W., bounded N. by Bolivia, E. by Paraguay, Brazil, Uruguay, and the Atlantic, S. by the Atlantic ocean and Patagonia, from which it is separated by the Rio Negro, and W. by the Andes, separating it from Chili. The Argentines dispute with Chili the right to the territory S. of the Rio Negro as far as Tierra del Fuego, according to the original division by the government of Spain. The area of the republic, including the undisputed portion of the Gran Chaco, is 841,000 sq. m. If to this be added that part of the Chaco from the Bermejo N. to lat. 22°, as claimed by the government, the area would be about 1,000,000 sq. m. The 14 provinces into which the country is divided, with their area and population, according to the census of 1869, are as follows:

PROVINCES.	Area, sq. m.	Population.
LITTORAL OR RIVERINE PROVINCES.		
Buenos Ayres.....	70,000	348,566
Corrientes.....	60,000	120,198
Entre-Rios.....	50,000	115,963
Santa Fé.....	20,000	75,178
ANDINE PROVINCES.		
Catamarca.....	35,000	79,551
Mendoza.....	65,000	59,269
La Rioja.....	35,000	48,493
San Juan.....	33,000	55,007
CENTRAL PROVINCES.		
Córdoba.....	60,000	208,771
San Luis.....	20,000	52,761
Santiago del Estero.....	95,000	132,763
Tucuman.....	28,000	108,602
NORTHERN PROVINCES.		
Salta.....	50,000	85,959
Jujuy.....	30,000	97,357
Total.....	591,000	1,526,738

These figures show an increase of 146 per cent. as compared with the census of 1836. All the provincial capitals bear the names of their respective provinces except that of Entre-Rios, which is Concepcion (*La Concepcion del*

000; Spaniards, 30,000; Irish, 30,000; English and Scotch, 10,000; Germans, 10,000; other nationalities, 30,000. The number of Italians at present in the province exceeds 60,000, upward of 40,000 of whom (or about one fourth of the entire population) are in the city of Buenos Ayres. In the upper provinces there are but few foreigners, Entre-Ríos alone excepted, where they are numerous and engaged in all branches of industry. In Santa Fé there are three prosperous colonies. Córdoba has perhaps 1,500 settlers. The most numerous class of foreigners are Italians, who are in general skilled in the building trades, and have found constant employment in the various splendid buildings erected of late years in Buenos Ayres; many of them are also engaged in market gardening. The Genoese are chiefly occupied in river navigation, the monopoly of which is in their hands. Besides this advantage, the crews of the river and coasting crafts have often equal shares in the ventures. The Spaniards present a less striking contrast with the Argentines, the Catalans prospering as wine merchants, the Andalusians as cigar dealers and shopkeepers, while the Galicians perform the duties of street porters, night watchmen, and domestics. The Basques, after the Italians the most numerous foreign community, are mostly bricklayers, milkmen, shepherds, saladero peons, &c., though some are rich and at the head of lucrative enterprises. To the Irish is due the development of sheep farming that enables the Argentine provinces to rival Australia in the production of wool. Many of them number their acres by thousands, and their flocks by hundreds of thousands. The aggregate number of sheep owned by the Irish is estimated at 30,000,000. Of the French, who are the most equally distributed in the provinces, some are wealthy wine merchants, trading with Bordeaux, and in general they are found in every branch of commerce, especially the fancy trade, which they monopolize. They assimilate more with the Argentines than do the English and Germans. The English and North Americans are seldom occupied in other than mercantile pursuits. The Argentines (*Argentinos*) are naturally active and intelligent. The Gauchos, or horsemen of the plains, are descendants of the Spanish colonists, and many of them have sprung from the best families of the peninsula. They live in rude huts built of mud, and subsist almost entirely on the flesh of oxen and game, both of which abound in the pampas, and are taken with the *lazo* or the *bolos*, a missile weapon wielded with astounding dexterity by the Gauchos. Of the Indians, who are chiefly of Araucanian descent, by far the larger number are independent and live in separate tribes, governed each by its cacique. They dwell in tents of hides, and their subsistence consists mainly of maize, which they procure from the whites in exchange for cattle, salt, and blankets made by their women, and of the flesh of mares, these animals never being ridden, but wholly

reserved for food. Some Indians are employed as farm laborers. As early as the 16th century missions were established to the east of Corrientes by the Jesuits, who did much toward civilizing the Indians; but after the expulsion of the order from South America, near the close of the 18th century, the natives relapsed gradually into savagism.—The coast line of the Argentine Republic, which measures 540 m., is generally low and sandy, and has no very good harbors. The principal port, Buenos Ayres, on the Plata, is 180 m. from the sea, and is difficult of access on account of the shallowness of the river. The only other important ports are Rosario, on the same river, 360 m., and San Nicolás, 310 m. from the sea, and Bahía Blanca and El Carmen on the seaboard. The northern and Andine provinces are for the most part mountainous, being covered with spurs diverging from the Chilian Cordillera. There are no volcanoes in activity; but signs exist of some extinct, such as that in the vicinity of Jujuy, from which issues every morning a spiral column of dust that extends many miles over the country. The town of Orán, in Jujuy, was overthrown by an earthquake early in 1872. Some peaks of the Despoblado chain in Salta attain a height of 14,000 ft.; and the culminating point of the Aconquija system, traversing Tucuman and Catamarca, reaches 17,000 ft. at its highest summit. The Córdoba chain, in the province of that name, is divided into two branches, but presents no lofty peaks. Among the mountains of the eastern provinces, the Yerbales in the N. E. of Corrientes are worthy of mention; and the southern portion of Entre-Ríos is bisected by hills of considerable height. With these exceptions, and those of the Volean, Ventana, and Guamini ranges in the S. E. of Buenos Ayres, this country may be regarded as a vast unbroken plain stretching from the foot of the Andes to the Atlantic and the river Uruguay, and from the Bolivian boundary to the frontier of Patagonia. This plain may be considered as forming two grand regions: one, from the Rio Negro to the Rio Salado, comprises the pampas; the other, N. of the Salado and W. of the Paraguay, embraces the desert of the Gran Chaco, which extends, with little interruption, far N. of the Bolivian limits. The vast tract of the pampas, over 300,000 sq. m. in area, is itself distinguishable into several subdivisions, differing in climate and products, although under the same parallel. Proceeding from Buenos Ayres, the first of these sub-regions presents for nearly 200 m. an alternate growth of clover and thistles; the next a covering of long grass and brilliant flowers, extending without a weed some 400 m. further westward; the third, reaching to the base of the Andes, one continuous grove of shrubs and small evergreen trees, so evenly set that a horseman may gallop at random between them without inconvenience. Change of season brings little variation in the aspect of the two regions last mentioned; but in the first remarkable

mutations occur. During the winter months the thistles and clover are exceedingly rich and strong, and herds of wild cattle are seen browsing in every direction. On the approach of spring the clover disappears, and nothing is distinguishable save an immense forest of giant thistles, tall enough to almost totally obstruct the view, and so closely set and so strong as to form an impenetrable barrier. In summer the thistles give place to a new and luxuriant growth of clover. The Gran Chaco is a vast and for the most part unexplored territory, the interior of which is exclusively inhabited by five nomadic tribes, distinct in language, but similar in physical appearance. The southern portion forms an immense desert interspersed with sand pools; the eastern, extensive plains and marshes, with here and there tracts entirely inundated, while the natural features of the northern part are plains of magnificent pasture, dense forests of useful timber, and numerous rivers and lagoons. Some colonies have been founded of late years and bid fair to prosper. The government offers liberal grants of land to settlers.—The Rio de la Plata, with the immense streams which form it, is one of the greatest, and certainly one of the longest, rivers of the western hemisphere. The traveller can take steamer at Montevideo and ascend without interruption to Cuyabá, in Maíto Grasso, over 2,000 m. But it is itself rather a vast estuary collecting the waters of large rivers, and pouring into the Atlantic an immense and turbid flood, which is perceptible more than 100 m. to seaward, and produces a powerful current amid the waters of the ocean to a distance of 200 m. The depth of the Plata is nowise proportionate to its width. At Montevideo, where the width is 75 m., a series of sand banks narrow the channels and render them of difficult navigation; and at Buenos Ayres, where the shores are 28 m. apart, even vessels of medium draft have to anchor 6 and sometimes 8 or 9 m. from land. Up to 1855 passengers and goods were brought ashore in carts mounted on huge wheels, that went out to meet the boats at a distance of two or three cables' length from the water's edge. In that year two handsome piers 1,300 and 1,950 ft. in length were constructed of wood and iron; but when the river is low the old expedient of carts has to be resorted to. Of the two great rivers which unite to form the Plata, the Paraná curves from S. to W. on the N. E. border to its junction with the Paraguay, at Tres Bocas, in lat. 27° 14' S., lon. 58° 30' W., whence it flows nearly S. to Rosario, in lat. 33°, then turns S. E., and falls into the Plata by several channels from 25 to 55 m. above Buenos Ayres. The river is navigable for the largest vessels to its junction with the Paraguay, 850 m.; 150 m. higher for small steamers; and 350 m. further up for small boats. Its chief tributaries in the republic are the Salado, which flows S. E. from the N. W. part of the province of Salta about 600 m., and empties below Santa Fé, and the

Tercero, which flows S. E., receives the Cuarto, and empties about 30 m. above Rosario. The Salado is said to be navigable from the plains of Salta. The Uruguay forms nearly the whole E. boundary of the republic, bordering on the provinces of Entre-Ríos and Corrientes, to its embouchure in the Plata by a channel 6 m. wide. This river is usually flooded from June to November, and is navigable for steamers up to Salto Grande, about 200 m. The Paraguay, after a long course through Brazil and on the frontier of Bolivia, forms the dividing line between the Argentine Republic and Paraguay for 350 m. to its confluence with the Paraná, 25 m. above Corrientes, receiving in that distance the Pilcomayo and Bermejo. These are both large rivers flowing S. E. through the Gran Chaco, but the former is too shallow for navigation, while the latter has been navigated by steamers for 1,200 m. by its tortuous course. The Colorado or Mendoza, formed by the union of various streams springing from the volcanoes of the Chilian Cordillera, holds a generally S. E. course and flows into the Atlantic at Union bay. It is navigable for upward of 100 m. from the sea. There is a second Rio Salado in the province of Buenos Ayres, S. of the capital, but it is dry for most of the year. The Negro, which forms the S. boundary of the republic as far W. as lon. 70°, falls into the Atlantic below El Carmen, and has been navigated almost throughout its entire course, or about 500 m. The pampæan plains are drained by innumerable streams, some of considerable volume, whose waters, for the most part saline, spread and are lost in the marshes or salt lakes that abound in those regions. Among them the Primero and Segundo are large but not permanent streams; while the Tercero and Cuarto, already mentioned, are perennial. The plains are interspersed with an infinite number of lakes and lagoons, for the most part salt W. of the Paraná and Paraguay, while those E. of these rivers are without exception fresh. In the province of Corrientes is an extensive lake, the Iberá, 130 m. long and 90 m. wide, which gives its name to a marshy territory of considerable area. The Paraná is by some geologists supposed to have at an early period taken its course through this lake; and many are of opinion that the latter is now filled by infiltration from the great river, although there exists no visible connection between them. No rivers run into it, but it supplies four of some magnitude. The Iberá during the season of the floods extends over an estimated area of 1,000 sq. m., but is navigable only for canoes. The chief permanent lake of the republic is the Guanacabe, in the province of Mendoza. There are also the Bevedero and the Urre Laguen, or bitter lake, both of some magnitude. The countless smaller lakes or lagoons usually disappear as soon as the rains have ceased, and leave the ground covered with a salt efflorescence to a depth of several inches, and in some places even of three feet.—The geolo-

gical features of the regions N. of the Plata present a striking contrast with those on the south. The former are elevated, and composed of granite, gneiss, and clay slate; and indeed all the rocks showing themselves above the plain of the Plata, in the Sierra Ventana S. of Buenos Ayres, in Entre-Ríos, Córdoba, and the upper provinces generally, are granitic, a superposition of pure white quartz rock associated with glossy clay slate occurring, however, over the granite of the Ventana. On the S. side of the Plata all rock formations disappear, and not even a pebble is to be found for hundreds of miles inland. The pampæan regions are characterized by a diluvial formation consisting of calcareo-argillaceous conglomerate gradually deposited during the lapse of ages, in what was once an arm of the Atlantic, but is now dwindled within the present limits of the estuary of the Plata. It may be observed that this same deposition is still rapidly progressing in the bed of the river, inasmuch that it is altogether likely that the great stream which, according to report, was navigable for ships of the heaviest burthen three centuries ago, will in the course of ages flow into the ocean by a delta, like the Nile or the Ganges, instead of entering it, as it now does, through a single mouth. In Entre-Ríos there occur at the bottom of the cliffs beds containing sharks' teeth and sea shells of extinct species, passing above into an indurated marl, and from that into the red clayey earth of the pampas, with its calcareous concretions and the bones of terrestrial quadrupeds, clearly telling of a large bay of pure salt water, gradually enroached on, and at last converted into a muddy estuary into which floating carcases were swept. The number of the fossil remains imbedded in the grand estuary deposit, says Darwin, must be extraordinarily great. A line drawn in any direction through these regions would, observes the same writer, cut through some skeleton or bones. Fossil mammalia of nine species have been found: the *megatherium*, of huge dimensions; the *megalonix* and *scelidotherium*, the latter edentate and probably as large as a rhinoceros, and both allied to the first; the *mylodon Darwini*, and another gigantic edentate quadruped; a large animal with an osseous coat in compartments, bearing some resemblance to the armadillo; an extinct kind of horse, the *equus curvidens*, indicative of the existence and disappearance of a native race before the introduction of the few individuals by the Spanish colonists; a pachydermatous animal, perhaps the same with the *macrauchenia*; and the *toxodon*, an elephant in size, a gnawer by the structure of the teeth, and probably aquatic like the manatee, to which it is allied.—The Aconquija mountain chain abounds in gold, silver, and copper ores; and the Famatina in La Rioja affords very fine silver ores. Iron has been found in the Gran Chaco. An immense mass of this metal, presented by Sir W. Parish to the British museum,

and pronounced to be of meteoric origin, is regarded by him as a genuine production of the soil. Salt, the most abundant mineral in the Argentine Republic, exists in a state of efflorescence covering immense tracts, and in countless brackish springs and pools; but nowhere is it so common as near Bahía Blanca. The salt occurring far inland consists for the most part of sulphate of soda, and perhaps 7 per cent. of common salt, and does not preserve meat well; while near the coast the proportion of common salt reaches 37 per cent., and the quality is superior. There are besides mines of rock salt in the country; and sulphate of soda and sulphate of magnesia, from which the magnesia of commerce is prepared, occur in various localities. Coal is found in the N. W. provinces, also gypsum, limestone, alum, mineral pitch, bituminous shale, and large quantities of sulphur; and there are extensive coal beds in the extreme S. W. angle of the country.—The climate, on the whole perhaps one of the finest in the world, exhibits nevertheless considerable variety. In the north the heat is great, and in some localities oppressive, save where tempered by fresh breezes from the Andes. On travelling southward a cooler temperature is experienced, and especially in the province of Buenos Ayres, where the climate closely resembles that of some portions of southern Europe. In the plains reaching from the Andes to the banks of the Paraná there is a great deficiency of moisture, while the countries E. of that river are refreshed by abundant and frequent rains. In Buenos Ayres, where a luxuriant vegetation shows great humidity, the climate is chiefly governed by the wind, a change of which not infrequently brings an alteration of from 20° to 30° in the thermometer, which rarely rises above 90° in the shade. The prevailing winds are northerly, and these, passing over extensive marshy and saline districts, produce on reaching Buenos Ayres a universal dampness, and upon the bodily system an extreme lassitude, inducing a liability to all the maladies consequent upon checked perspiration. Although the northerly are not generally regarded as unfavorable to health if the necessary precautions are taken, while they prevail the most trifling wound or hurt may terminate in lockjaw. The S. W. wind, or *pampero*, usually follows the northerly, and blows at times with great violence, driving back the waters of the Plata miles from the shore, and bearing clouds of dust so dense as to produce total darkness. The pamperos very frequently end in a heavy shower of rain, or rather mud, formed by the mingling of the water and the dust. The thunder and lightning during one of these storms are perhaps unequalled in any other part of the world. A disease called *el mal de siete dias* (the seven days' sickness), mainly prevalent among the lower classes, carries off an immense number of infants in the first week after birth. The following table shows the range of Fahrenheit's ther-

monometer in the shade at Rosario during the month of March, and at Buenos Ayres from April to September :

	March.	April.	May.	June.	July.	August.	Sept.
Monthly range.....	51°	26°	25°	28°	26°	25°	18°

—The soil of the Argentine Republic is extremely varied and productive, save in the S. plains, the coarse shingle of which is unfavorable to vegetation. As has already been seen, the pampas, and principally to the S. W. of the Paraná, afford rich and abundant pasturage. The E. flank of the Andes and the banks of the W. affluents of the Paraguay are clothed with dense forests, the timber of which is, however, unavailable owing to its distance from the sea. The trees are mostly of the mimosa family; and with the fruit of the algarroba, mixed with maize, the Indians make a sort of bread, while by fermentation they produce the *chicha*, an intoxicating liquor. In Salta the cinchona, various palms, and the *maté* or Paraguayan tea are indigenous; and in Salta and Santiago the

cactus foliosus, on which a cochineal insect feeds, grows to an enormous size. Aloes are very abundant, and from their fibrous materials the Indians manufacture nets, ropes, bags, &c., which they dye with indelible colors of their own preparation from native plants. The coca plant grows plentifully in Salta. Mixed with lime, the Peruvians chew it as a stimulant. Indigo is found in Corrientes, and also the shrub which nourishes the *clavillo*, an insect famed for the rich green dye it affords. The apple tree was introduced from Chili by the Indians, and forms veritable forests in the S. W. districts near the Andes. Figs, oranges, walnuts, and other fruits are common; and the peach tree is so abundant as to afford the principal firewood for the city of Buenos Ayres. Good wine is made in Mendoza. The sugar cane prospers in the northwest, and tobacco is extensively cultivated. The cotton tree flourishes in Catamarca, and red pepper is sent in large quantities to Buenos Ayres. Maize, potatoes, and the different European cereals are raised in almost all the provinces, and of wheat prodigious crops are produced, principally for export. But the exportation of productions of the soil has hitherto been inconsiderable compared to that of animal produce derived from the herds of cattle and horses in the pampas. An idea of the cattle-raising in eight of the provinces (there being no returns from the others) may be formed from the following statistics of the farming stock in 1866 :

PROVINCES.	Horned Cattle.	Horses.	Asses and Mules.	Sheep.	Goats.	Swine.
Buenos Ayres.....	6,000,000	1,800,000	30,000	60,000,000	5,000	115,000
Entre-Rios.....	2,500,000	600,000	7,500	6,000,000
Corrientes.....	2,000,000	375,000	60,000	1,000,000	10,000	4,500
Catamarca.....	185,000	4,000	40,000	80,000	121,000	2,500
Mendoza.....	210,000	71,000	7,500	230,000	70,000	8,500
Salta.....	255,000	50,000	50,000	150,000	95,000	2,500
San Luis.....	300,000	95,000	14,000	160,000	25,000
Tucuman.....	275,000	85,000	22,000	95,000	25,000

—In the forests of the republic there are jaguars, cougars or pumas (American lions), anteaters, and chinchillas as large as squirrels and much prized for the beauty of their furs. The tapir is common in the north. Deer abound in the pampas, as do wild dogs and armadillos; and there are three species of partridge. On the banks of the Río de la Plata is found the *cariguibaju*, known in commerce by its fur under the name of nutria; it is a carnivorous animal, of the size of a cat, web-footed, and its flesh is considered exceedingly delicate. The capybara, the giant of the rodentia, and the carpincho frequent the rivers. The Andine provinces abound in guanacos, llamas, and vicuñas; and the Gran Chaco is infested by the various feline animals already mentioned, besides wild cats, boars, myriads of noxious insects, spiders of monstrous proportions, enormous mosquitoes, and innumerable swarms of bees. Several varieties of venomous

snakes are met with, especially a *trigonocephalus*, the fiercest and most hideous of its kind, and a species of boa similar to the *traguvenado* or deer-swallower of Venezuela. The tocutuco and bizacha, rodent quadrupeds, are found in all directions throughout the pampas, rendering travelling dangerous from their burrowings. Condors, gallinazos, vultures, and other predacious birds abound in various districts; and the woods are peopled by numerous smaller birds of endlessly varied plumage. The rivers, and especially the Río Negro, abound in fish of all kinds, the lamprey, trout, pejerrey, sole, and ray or skate being those most prized. Seals are taken on the N. coast, as also sea lions and sea elephants; the latter often attain a length of 20 to 23 feet, and one will yield two hogsheads of oil. The breeding of mules has of late years declined, though considerable droves are still to be met with in the *estancias*. The sheep, although extremely nu-

merous, are, like the goats and hogs, of an inferior breed. A species of ostrich, smaller than that of Africa, is common on the plains, and hunted for its feathers, an article of export of some importance.—Almost the only manufactures of the Plata provinces are ponchos, saddle-cloths, ropes, &c., made by the Indians, and morocco leather, wooden bowls, and dishes from Córdoba, the principal manufacturing town.—In spite of wars, epidemics, droughts, and other obstacles to the material development of the country, the following tabular statement by Sr. Don Manuel R. García, Argentine minister to the United States, shows that the exports have quadrupled in quantity and quintupled in amount in the 17 years from 1853 to 1870:

ARTIC. LBS.	1853.	1870.
Salted ox hides.....	48,831	774,806
Dried ox hides.....	604,868	1,524,895
Horse hides.....	129,905	102,259
Hogsheds of tallow.....	17,665	108,884
Packages of wool.....	20,514	160,369
Sheepskins.....	1,393	67,214
Quintals of jerked beef.....	275,090	647,582
Total (tons).....	97,453	807,722
Value.....	\$6,990,770	\$30,204,690

This increase, large as it may appear, belongs to a small proportion only of the products of the country, the mineral and agricultural resources of which have not yet been developed, for want of hands, capital, and suitable roads. Official reports show the exports of the products of cattle to have been in the proportion of \$22 50 for each inhabitant in the province of Buenos Ayres alone in 1853, \$60 in 1860, and \$80 in 1870. The wool clip for 1866 was estimated at 100,000,000 lbs. The export duties on wool, bones, hides, and tallow amount to about 3,000,000 silver dollars per annum. The total of the exports from the port of Buenos Ayres to the United States during the year ending Sept. 30, 1870, was \$6,473,927 61; while that of the imports from the United States in the same period was but \$2,087,999, according to custom house returns. The balance of trade from Great Britain was in favor of the latter by over \$6,000,000, and that with France by about \$1,500,000. The imports mainly comprise cotton, woollen, and linen fabrics, machinery, coal, and iron. In 1869 there entered the principal ports 1,337 sailing vessels, with an aggregate of 401,070 tons, and 1,158 steamers; and there cleared 970 sailing vessels, with a total of 308,325 tons, and 1,158 steamers.—The highways of the republic are, with few exceptions, as nature made them, consisting merely of a beaten track across the pampas. There are four lines of railway in the province of Buenos Ayres. In Entre-Ríos there is also easy communication by river steamboats; but in the interior of Corrientes travelling is done exclusively on horseback. There are now (1872) six railway lines opened

for traffic, four of which diverge from the capital of the republic in different directions; the remaining two are from Rosario to Córdoba, and from Gualeguay to Puerto Ruiz. Besides these, there are two railways in course of construction, and five others projected. Along the lines already opened, new farms have been established, immense quantities of wheat sown for exportation, and the shipment of wool has so increased as at times to task the carrying power of the railways. In September, 1871, there were 1,230 m. of telegraph open, and over 2,630 m. in process of construction. A submarine cable has been laid between Buenos Ayres and Montevideo, and an important line is projected to unite the capitals of Chili and of the Plata provinces.—The Mauá bank was the first private bank established in Buenos Ayres (1858); the London and River Plate bank, established in 1863, does a large and remunerative business. The Argentine bank is of more recent date.—The business of the post office department has greatly increased in a few years; the number of letters passing through the Buenos Ayres post office in 1859 was but 400,000; in 1865 it amounted to 2,000,000.—The constitution of the Argentine Republic bears date May 15, 1853. The executive power resides in a president elected for six years by the representatives of the 14 provinces, 133 in number. The legislative authority is vested in a national congress, consisting of a senate numbering 28, two from each province, and a house of deputies, of 54 members. The vice president, elected in the same manner and at the same time as the president, is chairman of the senate, but has otherwise no political power. The president is commander-in-chief of the army, and appoints to all civil, military, and judicial offices; but he and his ministers are responsible for their acts, and liable to impeachment. There are five ministerial departments; interior, foreign affairs, finance, war and marine, and education and public worship. The governors of the provinces are elected by the people for a term of three years. The army of the republic consists, exclusive of the militia and national guard of Buenos Ayres (numbering 19,867 men), of 6,482 men—2,909 infantry, 2,861 horse, and 712 artillery; there are 29 generals, 273 commandants, and 632 subaltern officers. The militia and national guard may be called out in time of war. The navy comprises seven vessels of war, one of which mounts 12 guns. The public revenue is mainly derived from customs duties, which average 25 per cent. on imports and 10 per cent. on exports. The national expenditure is made up chiefly of the cost of the army and navy, and the interest of the public debt. The expenditure was considerably increased from 1867 to 1870, owing to the war with Paraguay. The official estimates of revenue and expenditure for the financial year 1869-70, presented to the national congress, were as follows:

January, 1813, the chief power was vested in the "Sovereign Assembly" formed in Tucuman, then the seat of government. About the same time Gen. José de San Martín, the governor of the province of Mendoza, conceived the project of crossing the Andes for the purpose of driving the Spaniards out of Chili. The enterprise proved successful, and Chili was freed after the memorable battles of Chacabuco and Maipú (1817-'18). Immediately afterward the Chilians and Argentines carried their united arms into Peru, and entered Lima in 1821. The Portuguese in 1816, under pretext of putting down anarchical movements set on foot in Uruguay by Artigas, descended into that territory and took possession of Montevideo, in spite of the protests of the Argentine government, then too busily engaged in preserving order at home and in carrying on the war of independence, to enter openly into hostilities against the invaders. The same year the independence of the United Provinces of La Plata was declared in Tucuman (July 9), in which city, after the dissolution of the sovereign assembly, a congress had assembled March 26, 1817, and promulgated a provisional constitution, Gen. Pueyrredon being named supreme dictator. The seat of congress was afterward removed to Buenos Ayres, in the hope of securing greater liberty of action; but in 1820 the directory fell, and in the following year a democratic form of government was established. The administration was composed of Gen. Rodríguez and two secretaries, Don Bernardino Rivadavia and Don Manuel García. The riverine provinces soon united themselves with Buenos Ayres, and this alliance led in 1824 to the organization of the republic, under the administration of Las Heras. Brazil forced the United Provinces into a declaration of war, and blockaded the city of Buenos Ayres, January, 1826; and, though the Argentine arms were for a time victorious by sea and land, the event served to prove the weakness of the union. It is important to remember that the size of the different provinces was extremely various, and that the character and interests of the population were no less varied. It may also be added that the difficulty of establishing communication between the provinces rendered useless at times prudent measures taken by the central government. There was almost a feudal aristocracy in the north; in the wide ranges of the pastures the herdsmen felt and exercised a rude power; but there was a greater degree of moderation in the agricultural states. Buenos Ayres, as the only seaboard state, and as much the richest, naturally took the lead, both in preparing the way for independence and in forming the confederacy. The higher classes possessed immense landed and other property. Many of them had been educated in Europe, and had introduced into South America the refinements of a high civilization, and hoped to extend those refinements over the whole country by

means of a form of government. But under their ideas this government was to be wielded by the rich and educated classes. Their party, the Unitarios, succeeded in framing the constitution of 1825, under which the nation was represented by a small aristocracy. Rivadavia was the first and only president of the confederation under this constitution. The greater part of the large province of Buenos Ayres took its political bias from the independent and republican tone of the cattle drivers and herdsmen, who knew their power, and were not averse to asserting it. They soon found a leader in Juan Manuel de Rosas, who was descended from a noble family of Spain. Untutored in the arts of refinement, and at once daring in the highest degree, ambitious, and cunning, he soon found numerous supporters among the masses of the people, and especially after he had succeeded in extending the limits of the province of Buenos Ayres, by subduing the savages of the pampas and other indigenous tribes, who were implacable enemies of the *gauchos* or herdsmen. No sooner had he espoused the cause of the federalists than his popularity spread to the provinces, and he gained the sympathies of many prominent personages who regarded with a jealous eye the recent excesses of military power. He had opposed the Unitarios at the time of the union, although unsuccessfully; but by 1827 he had acquired sufficient influence, and found himself certain of the aid of other popular chieftains, such as Bustos, governor of Córdoba, Ibarra, commandant of Santiago, Quiroga, of La Rioja, and Lopez, of Santa Fé. They protested against the constitution and government of 1825, and took up arms in force in support of their protest. Rivadavia, successor to Las Heras, seeing himself powerless to establish a unitarian constitution, and aware that he could neither carry on the war against the Brazilians nor obtain a peace, resigned power, and Rosas and his colleagues chose Dorrego governor of Buenos Ayres. Dorrego made a treaty of peace with Brazil, through the mediation of England, in 1828, from which year dates the recognition of the Banda Oriental of Uruguay as an independent state, under the triple guaranty of Great Britain, the Argentine Republic, and Brazil. A confederation, based upon voluntary alliance was formed in January, 1831, between the provinces of Buenos Ayres, Corrientes, Entre-Ríos, and Santa Fé, which were soon joined by the other provinces. But some of the officers who had commanded in the late war now began to regard with distrust the triumph of federal principles under Dorrego and the other governors; and the established army of the republic set on foot a counter-revolution, headed by one Lavalle, an officer of some distinction. Lavalle defeated Dorrego and Rosas, and shot the former without a trial. Rosas, however, with Quiroga of La Rioja and Lopez of Santa Fé, formed a new league and overthrew Lavalle, who resigned his post, Rosas be-

ing chosen in his place, which he held till 1832. Two governments, the first under Balcarce, and the second under Viamont, now followed each other in the space of a few months, neither being able to maintain itself, as Rosas held the army under his control. After the fall of Viamont, Rosas was reelected governor of Buenos Ayres, a position which placed him at the head of the foreign relations of the country, and gave him a very general control of its internal affairs. His term expired in 1835, when he refused to be again a candidate. Five times the honor was tendered to him, and as often refused. He was then offered the dictatorship for five years, which he accepted, and the appointment was twice renewed. He held the office till 1852, and was the sole and uncontrolled ruler of Buenos Ayres, and practically of the Argentine Republic, during the whole of that time. From 1827 to 1852 there was no meeting of the national congress or constituent assembly. It is difficult to characterize precisely the use which he made of these unlimited powers. He has been represented as an arbitrary and bloody tyrant, and accused of the treacherous murder of all the friends who placed him in power. He certainly ruled with a strong hand, and was neither slow nor scrupulous in his means of defending or of advancing himself; but he maintained a government under which his country increased in population and material prosperity, notwithstanding continual internal dissensions and foreign wars, and retained a strong and generally triumphant party of friends till the last. With the idea that all the provinces of the former viceroyalty of Buenos Ayres belonged to the Argentine Republic, a contest was long kept up to attempt to bring into it the states of Paraguay and Uruguay. The former, protected in part by its natural position, and more by the policy of isolation and the strong executive power of its singular dictator, Francia, almost entirely escaped foreign conflict. But Brazil had ever in view the conquest of the latter, while the Argentine government saw the importance of that territory, and especially the necessity of checking the ambition of the neighboring monarchy. The civil dissensions in the Banda Oriental exercised a marked influence on Argentine politics, and the movements headed by Oribe and Rivera served Rosas as a pretext for his intervention in Uruguayan affairs and for the aid given by Brazil to the enemies of the Argentine dictator. Oribe was a partisan if not a creature and tool of Rosas. To him there was opposed a strong faction led by Rivera, a man who had raised himself to influence much in the manner employed by Rosas in Buenos Ayres. The matter came to a war, first of blockades and then of armies, between Oribe supported by Rosas on the one hand, and Rivera sustained by the Argentine exiles in Montevideo, and also by a French fleet, on the other. The intervention of the French was induced by a quarrel which had arisen between a French vice

consul and the dictator. The French difficulty was settled by the appointment of a new consul, and in 1840 peace was concluded between the confederation and Montevideo. This peace was not of long duration, and in 1845 Great Britain and France, at the special request of the emperor of Brazil, interfered, on the plea of enforcing the treaties of 1828 and 1840. The allies blockaded Buenos Ayres; seized the Argentine fleet, then engaged in blockading Montevideo, and the island of Martín García, which commands the entrances of the Paraná and Uruguay; opened the Paraná, which Rosas had closed to vessels bound to Paraguay, and offered convoys as far as Corrientes, where in repeated attempts by the dictator to oppose the passage of the combined fleets the Argentines sustained heavy losses. This state of things lasted three years, at the end of which period England withdrew (July, 1848), but France continued hostilities six months longer. The rival factions in Uruguay, one of which was supported by Brazil and the other by Rosas, occupied the latter many years, while the opposition party in his own state was gradually becoming too powerful for him. This party, headed by Urquiza, governor of Entre-Ríos, was now armed and acting in conjunction with the natural enemy, and at the battle of Monte Caseros, Feb. 3, 1852, Rosas was defeated; but, more fortunate than Dorrego had been, he was enabled to escape to England. Vicente Lopez now became provisional governor of the province of Buenos Ayres. But, by a sudden *coup d'état*, Urquiza, having the army at his disposal, put himself at the head of the government as dictator, not five months after the deposition of Rosas. The first use of his power was to acknowledge the independence of Paraguay. He also secured the future free navigation of all the rivers flowing into the Plata, a wise measure which still remains in force. But this new assumption of dictatorial power produced immediate irritation. Having to attend congress at Santa Fé, he had hardly left the capital when (Sept. 11, 1852) a revolution broke out, and Valentine Alsina was chosen governor of Buenos Ayres. The province of Buenos Ayres, with this government, determined to maintain itself as a state independent of the confederation, and another revolution in December, which temporarily changed the governor, did not alter this purpose. The congress of the confederation did not assemble till Nov. 20, all the states being then represented except Buenos Ayres, and Urquiza was instructed to suppress the rebellion in that state. It again met Jan. 22, 1853, and went on with the work of forming a constitution. It also recommended the president to take all means to stop the civil war and bring Buenos Ayres back to the confederacy. The new constitution of the confederation, which is still in force, was promulgated May 1, 1853. It was framed in the apparent expectation that Buenos Ayres, the richest and most important, as the only mari-

time state of the confederacy, might be induced to return to it, and accordingly fixed that city as the capital. The constitution, with some slight modification, was copied from that of the United States of North America, as being a federal government of independent states. It guarantees the free navigation of the rivers, and provides that there shall be no duties on goods carried from province to province; grants to foreigners all civil rights; provides for their naturalization after ten years' residence, which term may be abridged at the discretion of congress; and makes other provisions for the encouragement of immigration. It went into effect at the end of the year. Urquiza was chosen president for six years from March 5, 1854. The seat of government was established at Bajada del Paraná, in the province of Entre-Ríos. Meantime, in Buenos Ayres a new constitution had also been formed in January of the same year, but not without a hope expressed and provision made for a future return to the confederation, which soon after seemed probable. That province was invaded by a party of filibusters under one Costa, and Urquiza was suspected, or at least accused, of having fostered the movement. This he promptly denied, and sent his forces to help to repel them; which friendly act failed to bring about an entire reconciliation, but resulted in good will between the parties, and two treaties of peace signed at Buenos Ayres, Dec. 20, 1854, and Paraná, Jan. 8, 1855. They provided for independent governments, but contained stipulations for much mutual assistance. Urquiza continued president of the Argentine Confederation, and Pastor Obligado was reelected governor of Buenos Ayres for a term of years. Upon the unanimous request of the congress of the confederation, negotiations were reopened on the subject of reunion, Oct. 10, 1855, and Juan Bautista Peña was sent to Paraná for the purpose. But the discovery that his authority did not extend to merging the two sovereignties, produced much irritation in the confederation, at the same time that another event occasioned discontent at Buenos Ayres. On Dec. 24, 1855, some Argentine refugees from Montevideo, under Gen. Flores, disembarked at Santa Fé to invade the province of Buenos Ayres. Gen. Bartolomé Mitre repulsed them, and in his turn invaded the province of Santa Fé, in which step he was sustained by his government. Upon this, not only was the mission of Peña closed, but the Argentine government signified to him (March 18, 1856) that the treaties of Dec. 20, 1854, and Jan. 8, 1855, were annulled. Differential duties levied by Urquiza upon all vessels from Buenos Ayres bound up the Plata and its tributaries gave rise to serious hostilities, which were renewed at intervals during four years, until Nov. 11, 1859, when Buenos Ayres was reunited to the republic. In 1860 Urquiza was succeeded in the presidency by Dr. Santiago Derqui; and in the following year the exclusion of the deputies of

Buenos Ayres from congress, on the ground of unconstitutional election, led to the renewal of hostilities. Gen. Bartolomé Mitre of Buenos Ayres defeated the Argentine troops at Pavón (Sept. 17, 1861), and was provisionally intrusted with the government, Derqui having abdicated. A convention appointed to revise the old constitution adopted a new one, appointing Buenos Ayres provisional capital of the republic, being at the same time the state capital. In October, 1862, Mitre was elected president of the Argentine Republic. Urquiza in the mean time remained on the defensive in Entre-Ríos, but was soon induced to accept the government of that province, which had entered into the newly constituted republic. An insurrection headed by Gen. Peñalosa, who for nearly two years held the provinces of Catamarca, San Juan, and Córdoba, terminated in his capture and execution (1863). In 1864 N. Aguirre was elected president of the Banda Oriental del Uruguay, from the ranks of the *blancos* (whites) or reactionary party; and Venancio Flores, the chief of the *colorados* (reds) or liberal party and the unsuccessful candidate for the presidency, placed himself at the head of an insurrection and readily obtained the aid of Brazil, in spite of the repeated protest of Lopez, president of Paraguay, to the government of Rio de Janeiro. Lopez now ordered the capture of a Brazilian steamer on its passage up the river to the province of Matto Grosso, and the detention of the crew and passengers as prisoners of war, Nov. 11, 1864. In the following month a Paraguayan army invaded Matto Grosso, sacked Cuyabá, the capital, and five other towns, and took possession of the diamond mines. Aguirre had applied to Lopez for aid, which was at once promised; but the Paraguayan troops could only reach Uruguay by passing through the Argentine province of Corrientes, and Mitre refused them permission of transit. In 1864 Flores was elected and in 1865 assumed the functions of president, the city of Montevideo being occupied by Brazilian troops. Fearing now from the attitude of the Argentine Republic that it would join the alliance against him, Lopez seized two Argentine war vessels in the bay of Corrientes, April 13, 1865, and the next day that city was occupied by Paraguayan forces, who formed a provisional government composed of three Argentine citizens, and declared the provinces of Corrientes and Entre-Ríos to be annexed to Paraguay. War was declared by the Argentine Republic against Paraguay April 16, a like declaration having been issued by the national congress of Paraguay against the Argentine Republic on the 18th of March. On May 1 an offensive and defensive alliance was secretly entered into between the Argentine Republic, Uruguay, and Brazil, against Paraguay, the allies "solemnly binding themselves not to lay down arms until the existing government of Paraguay should be overthrown." In June the city of Corrientes was recaptured

by the Argentines, but was soon after again invested by the invaders. During the first two months the war was chiefly carried on in Corrientes, generally with heavy losses to the Paraguayans, who, however, had by August succeeded in taking one or two towns in the adjacent Brazilian province of Rio Grande do Sul. But their advancing army on the river Uruguay, numbering 7,000, was defeated at Yatay, and finally surrendered in Uruguayana to 10,000 Uruguayans and Argentines. In November following the Paraguayan army had evacuated the Argentine territory, and the close of December found the allies, 35,000 strong, at Corrales on the N. shore of Corrientes, ready to cross the Paraná and carry the war into the heart of Paraguay. Lopez, commanding in person, was unable to defend his frontiers, and retired northward before superior forces, fighting for every inch of ground. This obstinate defence terminated with the battle of Lomas Valentinas, Dec. 25-27, 1868, having lasted upward of three years. The war continued, however, until March 1, 1870, when Lopez was defeated and killed at Aquidaban. (See PARAGUAY.) In 1866, in some provinces, especially those bordering upon Paraguay and Bolivia, great dissatisfaction with the continuance of the triple alliance and the war had been expressed, and repeated attempts made to induce the separation of some of the northern provinces from the Argentine Republic; but these disturbances were easily put down. Bolivia, in the same year, protested against the treaty of alliance, asserting her right to a part of the Gran Chaco claimed in the treaty by the Argentine states. On Dec. 10 a convention to reform the constitution of the republic met at Santa Fé; the only important measure adopted was the renewal of the permission to congress to levy duties on exports. An insurrection headed by one Videla broke out in Mendoza, San Juan, and La Rioja, for the purpose of separating the interior provinces from the republic; it was put down in April, but the leaders escaped. The opposition to the war had been increasing in strength, and was vehemently expressed in 1868 by Alsina, governor of Buenos Ayres, who denounced the contest as barbarous, murderous, and fatal. A bill which passed congress in the same year to make Rosario the national capital was vetoed by President Mitre. In April, 1870, a formidable rebellion broke out in Entre-Ríos, headed by Gen. Lopez Jordan, the first act of which was to murder Gen. Urquiza, Jordan's father-in-law, sack his palace, and confiscate his property. Two of Urquiza's sons were murdered in Concordia; and Jordan, having forced the state assembly to appoint him governor, issued a proclamation of liberty, and appealed to the national government for immunity from punishment. It was not until April, 1871, that the national troops, after immense losses, succeeded in quelling this rebellion. In March, 1871, the city and neighborhood of

Buenos Ayres were visited by yellow fever; all business was interrupted for several weeks, and the estimated mortality during the 100 days preceding the 30th of April was 26,000. Toward the close of the year a controversy arose between the Argentine Republic and Brazil, the former having protested against alleged breaches by the Brazilians of certain articles of the treaty of alliance of May 1, 1865. But Gen. Mitre brought his negotiations to a successful termination in October, 1872; and the Argentine government was to commence negotiations with Paraguay concerning boundaries before the end of the year.

ARGIVES (Gr. *Ἀργεῖοι*), the inhabitants of Argos or Argolis, in ancient Greece. During the Trojan war they were the most prominent among the Greek tribes, as Agamemnon, the Greek commander-in-chief, was an Argive. For this reason Homer, and following him some of the Roman poets, often use the name Argives as a generic appellation for all Greeks.

ARGOL. See **ΤΑΙΤΑΡ.**

ARGOLIS. See **ARGOS.**

ARGONAUT. See **NAUTILUS.**

ARGONAUTS, a name given from that of their ship, the *Argo*, to a band of heroes of Greek antiquity, who, according to the legend, first navigated unknown and dangerous seas. The poets have given different versions of the tradition, but the story generally accepted is briefly as follows. Jason, the son of Æson, was ordered by his uncle Pelias, king of Iolcus in Thessaly (who had been warned by the oracle to dread his nephew), to capture and bring to him the golden fleece of the ram which had carried Phrixus and Helle when they fled from their stepmother Ino. Phrixus had nailed the fleece to an oak in the grove of Mars in Colchis, where it was watched by a sleepless dragon. Joined by the principal heroes of Greece, whom he had invited to take part in the adventure, Jason set sail from Iolcus in the fifty-oared ship *Argo*, named from Argos, son of Phrixus, who had built it for the expedition. The heroes landed first in Lemnos, where the Lemnian women, who on account of the anger of Venus had slain their husbands, detained them two years. The Doliones, whom they next visited, at first received them hospitably, but afterward, mistaking them for Pelasgians, attacked them; and Jason in the battle killed their prince. In Mysia, their next landing place, Hylas, led away by a nymph, and Hercules and Polyphemus, who were searching for him, were left behind. In the land of the Bebryces King Amycus, who had challenged the heroes to a boxing match, was slain by Pollux. Continuing their voyage, they reached the Symplegades, two floating islands which crushed, in dashing against one another, whatever came in their way. Availing themselves of an artifice taught them by the seer Phineus and Juno, who acted as their pilot, they let loose a dove, only the tail of which was crushed by the colliding rocks, and the Argonauts

passed safely between as the islands rebounded. The islands from this time ceased their dangerous movements. Reaching Colehis at last, the heroes sought the king, Æetes, who promised the fleece to Jason on condition that he should yoke to the plough two fire-breathing bulls, and sow the dragon's teeth left by Cadmus in Thebes. Aided by the daughter of Æetes, Medea, a powerful enchantress, who had fallen deeply in love with him, Jason accomplished these tasks; but finding Æetes plotting treachery, the hero, again assisted by Medea's enchantments, seized the fleece, carried it on board his ship, and set sail, accompanied by Medea and her brother Absyrtus. Pursued by Æetes, Medea killed Absyrtus, and, throwing his body piece by piece into the sea, delayed the king, who stopped to gather the remains of his son, while the Argonauts escaped. But the mast of the Argo, which was made of Dodonian oak having the gift of prophecy, told the heroes that for the crime against Absyrtus they were condemned to undergo innumerable difficulties on their homeward voyage. Having been absolved by the enchantress Circe, they escaped Scylla and Charybdis with the help of Thetis, eluded with the aid of Orpheus the enticements of the sirens, and after four months of continued danger reached Ioleus. The Argo was consecrated by Jason on the isthmus of Corinth to Neptune.

ARGONNE, a mountainous and wooded region of N. E. France, forming a part of French Lorraine and Champagne, extending along the rivers Meuse and Aisne nearly 47 m. from Sedan (Ardennes) to beyond Ste. Ménéhould (Marne). It is bounded N. by the Ardennes and S. by the Meuse mountains, and contains many forests and ranges with several almost inaccessible passes. W. Argonne, or the Argonne forest proper, a wooded elevation 800 to 900 ft. high, extends over 30 m., with a breadth varying from 1 to 8 m., from the sources of the Aisne, along that river and the Meuse northward as far as Chêne-Populeux, separating the fertile plains from the barren steppes between Vitry and Sézanne, familiarly called Champagne Pouilleuse. The forest of E. Argonne, 600 to 900 ft. high, including in the N. the forest of Apremont, 1,225 ft. high, runs parallel with W. Argonne along the E. bank of the Meuse. The forest of Argonne contains several defiles renowned in history, among them the battlefield of Valmy, and has therefore been called the French Thermopylæ. Several important military movements and actions took place within its limits during the Franco-German war of 1870, preceding the battle of Sedan.

ARGOON, or Argun, one of the two chief branches of the Amoor river. Under the name of Kerulun or Kerlon, it rises about 30 m. S. E. of the sources of the Onon, S. of the Kentei mountains in Mongolia, and runs N. N. E. through the N. part of the desert of Gobi, about 500 m., to Lake Kulon or Dalai Noor

(holy lake). Thence, taking the name of Argoon, it flows generally N., with large bends, about 400 m., between the Russian and Chinese territories, to its junction with the Shilka, forming the Amoor. Its chief affluents are the Khailar, Khalkha, and Gasimoor, the latter running almost parallel with the Shilka.

ARGOS, or Argolis (anciently also *Argia* and *Argolica*), the N. E. part of the Peloponnesus, between the bays of Ægina and Nauplia, the Saronic and Argolic gulfs of the ancients. The eastern continuation of the northern mountain range of the peninsula surrounds a part of the inhabited shores, which bear marks of volcanic convulsions, and the plain of Argos, which is fertile, but rendered unhealthy by marshes. The chief mountain group is the Malevo, called by the ancients Artemision, on the Arcadian boundary, which rises above 5,000 feet. The largest plain is situated near the town of Argos, behind the bay of Nauplia, watered by the river Planitza, the classical Inachus. Only a few other spots are fit for agriculture, on account of the want of water, as all the streams except the Planitza and the Kephalaria (anc. Erasinus) dry up. But the many bays render Argolis favorable for navigation. In the earlier times of antiquity Argolis was strictly the plain surrounded on the west by the Arcadian mountains, and on the north by those of Phlius, Cleonæ, and Corinth. In the Roman epoch Argolis represented the eastern part of the Peloponnesus, bounded, on the land side, N. by the territories of Sicyon and Corinth, W. by Arcadia, and S. by Laconia. Argolis belongs to the earliest cultivated regions in ancient Greece. From the remotest times it was divided into the kingdoms of Argos, Mycenæ, Tiryns, Trozene, Hermione, and Epidaurus, which all afterward formed republics. About 750 B. C. the city of Argos, under Phidon, was the leading state of the Peloponnesus. Its power sank in its wars with Sparta, waged for the possession of the district of Cynuria, on their confines. Cynuria was lost about 550, and a defeat near Tiryns in 524 completed the decay of Argos. In the Peloponnesian war it sided with Athens. It early joined the Achaean league, and, on its fall, was included in the Roman province of Achaia.—In the present kingdom of Greece, Argolis is the main portion of a nomarchy called Argolis and Corinth, and embracing besides these territories a part of ancient Achaia and the islands of Spezzia and Hydra; area, about 1,900 sq. m.; pop. 128,000. Nauplia is the capital.—The town of Argos is situated near the head of the gulf of Nauplia, 20 m. S. S. W. of Corinth; pop. about 8,000. It suffered much in its capture by the Venetians in 1686, and its recapture by the Turks in 1706. Remains of its cyclopean walls, as well as of a grand amphitheatre hewn in the rock, are still to be seen.

ARGOT. See SLANG.

ARGUELLES, Augustin, a Spanish statesman, born at Riba de Sella, in Asturias, in 1775, died

in Madrid, March 23, 1844. He was one of the committee of the cortes of Cadiz which drew up the constitution of 1812, limiting the royal power. On the re-establishment of absolutism under Ferdinand VII. he was exiled to Ceuta, and thence transferred to a prison in the Balearic islands. The revolution of 1820 restored him to political life. On the restoration of Ferdinand he fled to England, where he remained until he was recalled in 1833 by the rezent Christina. In the cortes he opposed the government party until the accession of Mendizabal to power, when he joined him with the expectation of restoring the constitution of 1812. In 1836 he was appointed a member of the council of regency, and in 1837 a member of the senate. He was tutor to Queen Isabella and her sister.

ARGUS, in Greek mythology, a wondrous person with a hundred eyes, or, as others have it, eyes all over his body, of which only two slept at a time. Set by Juno to watch the priestess Io, transformed into a white cow, he was lulled to sleep by Mercury, who played soothing tunes on the pipe of Pan, and then slew him with his sword.

ARGYLSHIRE, or Argyllshire, a western county of Scotland, including several islands near the coast, and bounded on the land side by the counties of Inverness, Perth, and Dumbarton; area, 3,255 sq. m.; pop. in 1871, 75,635. It is remarkable for its picturesque character rather than for cultivation. The population is perhaps the lowest in the British isles, about 24 to the square mile, and still on the decrease, owing to the policy of the great land owners, which has been to remove the tenantry, and to create extensive sheep walks. In 40 years the loss of population has been 25 per cent. The mountain district of Argyleshire contains Cruachan Ben, rising to the height of 3,669 feet, with many other lofty hills, celebrated in Scottish poetry. The largest of the inland lakes is Loch Awe. The mountains are chiefly of granitic formation. Of the islands, Mull, Islay, Coll, Tiree, Jura, Iona or Icolmkill, and Staffa are chiefly noteworthy. Argyleshire is not rich in mineral resources. Lead, copper, and coal are worked, but not in very great quantities. The raising of cattle and sheep is carried on with great success. The moors yield abundance of game, grouse, ptarmigan, and blackcock; the red deer is also found. The proprietorship of this large county, which comprises more than one tenth of the area of Scotland, is in few hands. The duke of Argyll, the marquis of Tweeddale, and the marquis of Breadalbane are the chief land owners. There are various natural curiosities, the most remarkable of which are the columns and cave of Staffa. Gaelic is still generally spoken, although of late years the English language has begun to supersede it. The county is popularly divided into the districts of Argyle, Cowal, Kintyre, Lorn, Appin, Islay, and Mull. Capital, Inverary.

ARGYLL, or Argyle, Earl and Duke of, titles in the Scottish peerage held respectively since 1457 and 1701 by the heads of the family of Campbell (called by their Gaelic dependants Mac Callum More, "Campbell the Great"), who had been Lords Campbell since 1445, and who are also English peers. **I. Colin**, 2d Lord Campbell, in 1457 made earl of Argyll, died May 10, 1493. He was appointed master of the king's household in 1464 by James III., subsequently served as ambassador to England and later to France, was justiciar or lord justiciary, and finally lord high chancellor of Scotland. He acquired by marriage the estates and titles of Lorne, which still remain in the family. **II. Archibald**, 2d earl, commanded the vanguard at Flodden Field, Sept. 9, 1513, and was killed in the battle. **III. Archibald**, 5th earl, died in 1575. He was one of the most important adherents of Mary, queen of Scots, and commander of her forces at the battle of Langside in 1568. He was one of a council of nobles who virtually ruled Scotland after the assassination of Murray. After the murder of Lennox he was an unsuccessful candidate for the regency. He was appointed, however, a privy councillor, and in 1572 lord high chancellor. **IV. Archibald**, 8th earl, born in 1598, beheaded at Edinburgh, May 27, 1661. In 1633 his father, the seventh earl, announced his conversion to the Roman Catholic faith, and was compelled five years before his death to surrender to Archibald, then Lord Lorne, nearly all his estates. Immediately on his succession Argyll joined the side of the Scottish church against the innovations of Charles I. In spite of this opposition, the king, knowing his power in Scotland, made him a marquis in 1641. On the breaking out of the civil war he at once joined the estates against the king. He was made commander of the army sent against Montrose, but was so signally defeated by that general in two engagements that he almost immediately resigned. He afterward went to meet the king at New-castle, and, rejoining the royal side, took part later in the coronation of Charles II. at Scone, Jan. 1, 1651, placing the crown with his own hands upon the king's head. Not long after, however, he submitted to Cromwell after the battle of Worcester, and subsequently sat for Aberdeen in parliament under the protector's son Richard. At the restoration in 1660, he endeavored to make still another change, and hurried to London to conciliate the king; but he was imprisoned in the tower, and soon after sent to Scotland, where he was tried for high treason, found guilty, and beheaded. **V. Archibald**, 9th earl, beheaded at Edinburgh, June 30, 1685. He had remained faithful to the king during the revolution, and therefore at the restoration his father's estate and earldom (the marquissate having expired) were restored to him. But he refused to take the test oath, unless with the qualification "as far as is consistent with the Protestant faith." For this he was convicted of high treason and sentenced

to death, but escaped for a time by disguising himself as a page, and going, in the suite of his stepdaughter, Lady Sophia Lindsay, to Holland. Returning at the head of an army, he was defeated, captured, and immediately executed. **VI. Archibald**, 10th earl and 1st duke of Argyll, son of the preceding, died in September, 1703. He was acknowledged earl in 1689 by the convention of estates of Scotland, though his father's attainder was not formally reversed until several years later. He took an active part in the revolution of 1688-9, which placed William and Mary on the throne, and at the wish of the convention tendered the coronation oath to the king. The latter rewarded his services by several important appointments, and on June 23, 1701, conferred upon him the title of duke. **VII. John**, 2d duke, born Oct. 10, 1678, died Sept. 3, 1743. Immediately on his succession, although he was but 25 years old, he was appointed to nearly all the offices before held by his father, as an extraordinary lord of session, privy councillor, &c. In the reign of Queen Anne he was prominent in bringing about the union of Scotland and England, and for his services in this matter was made Baron Chatham and earl of Greenwich in the peerage of England. He served with great distinction in four campaigns in Flanders, and was made a lieutenant general. He several times changed his political views to suit the dominant party; in reward of the first of these changes, in 1710, he was appointed ambassador to Spain. On the accession of the family of Hanover, which he aided efficiently, he was made commander-in-chief of the army in Scotland, and took a prominent part in repressing the rebellion of 1715. His influence at court at this period was also very great. On April 13, 1719, he was made duke of Greenwich, a title which became extinct at his death. **VIII. Archibald**, 3d duke, brother of the preceding, born in June, 1682, died April 15, 1761. He was appointed, soon after he became of age, lord high treasurer of Scotland, and in 1710 was made lord justice general for life. After he succeeded to his brother's title in 1743, he had almost entire control of the Scottish government. He left no issue, and the title devolved upon his cousin. **IX. George John Douglas**, 8th duke, Baron Sundridge and Lord Hamilton (titles first held by the 5th and 6th dukes) in the peerage of England, 2d son of John Douglas Edward Henry, 7th duke, born April 30, 1823. His elder brother died young, and he succeeded his father April 26, 1847. Even before his succession he took a prominent part in Scotch politics, especially in the discussion regarding the Presbyterian church. On subjects connected with this he published in 1842 "A Letter to the Peers on a Peer's Son," and later several other pamphlets. In the controversy he was an adherent of Dr. Thomas Chalmers, but did not agree with that clergyman in his separation from the church. After his

succession to the title and his seat in the house of lords, he became prominent as a debater. He has generally sided with the liberals. In 1852 he was appointed lord privy seal, under the ministry of Lord Aberdeen. This office he retained under Lord Palmerston till 1855, when he was made postmaster general. He retired in 1858, but in 1859 he was again made lord privy seal, and retired in 1866. In 1868 he was appointed secretary of state for India in the Gladstone cabinet. The duke has also become distinguished in science and literature. In 1854 he was elected lord rector of the university of Glasgow. His principal work, "The Reign of Law," was published in 1866. On March 21, 1871, the marquis of Lorne, his eldest son, was married at St. George's chapel, Windsor, to the princess Louise, fourth daughter of Queen Victoria. This was the first instance of the marriage of the daughter of a reigning sovereign of England to a subject.

ARGYRO-KASTRO, a town of Turkey, in Albania, on the river Deropuli, an affluent of the Voyutza, 46 m. N. W. of Janina; pop. about 7,000. It is built on the side of a mountain, and the streets are so steep that persons on horseback are obliged to dismount. The streets are separated by ravines, planted with gardens. There is a strong castle, which was enlarged by Ali Pasha, and has accommodations for 5,000 men.

ARGYROPULOS, Johannes, one of the principal revivers of Greek learning in the 15th century, born in Constantinople about 1415, died in Rome, where he held a professorship of philosophy, about 1486. He was instructor in Greek to the son and grandson of Cosmo de' Medici at Florence, whence he removed to Rome. His principal works are some Latin translations of Aristotle. He was strongly prejudiced against the Roman writers, and declared Cicero to have been alike ignorant of Greek and of philosophy.

ARIADNE, according to Homer, daughter of Minos, king of Crete, and of Pasiphaë. When Theseus landed at Crete, with the tribute of the Athenians for the Minotaur, Ariadne fell in love with him and gave him a clew of thread by means of which he found his way out of the labyrinth. Theseus offered her his hand in token of his gratitude. Ariadne eloped with him, but as they arrived upon the island of Naxos she was killed by the arrows of Diana. According to the common tradition, Theseus abandoned her upon the island of Naxos, when Bacchus married her, and after her death transferred the crown which he had given her at their wedding to the stars.

ARIALDUS, a deacon and martyr of the church of Milan, born near Milan in the first half of the 11th century, died in that city, June 28, 1066. He began to preach against the corruptions of the clergy at Milan about 1056. Aided by Landulphus, a young noble even more eloquent than himself, he aroused the popular feeling to such a degree that Pope Nicholas II. sent

two legates to Milan to investigate the matter. They sustained Arialdus, but did not succeed in putting an end to the prevailing corruption. After the election of Pope Alexander II, the excitement again broke out at Milan, fomented by Arialdus and Erlembaldus, the brother of Landulphus. Pope Alexander excommunicated the archbishop of Milan, and reproved the other ecclesiastics. But even this did not conquer the abuses; and although Arialdus continued to preach against them, the fickle Milanese became jealous of the attacks from Rome on their clergy. Taking advantage of this divided state of public opinion, his enemies had Arialdus assassinated on a desert island in Lake Maggiore. His name was enrolled in the list of martyrs by Alexander II.

ARIANISM, a theological system in the early Christian Church, named after Arius, a presbyter at Alexandria. In opposition to his bishop Alexander, Arius asserted that there was a time when the Son was not coequal, since the Father who begot must be before the Son who was begotten, and the latter therefore could not be eternal. As many prominent bishops sided with Arius, synods were called on both sides, and the most acute intellects of the church discussed the question. The general council of Nice (325), attended by 300 bishops, condemned Arius and declared the Son to be consubstantial with the Father; but Arius nevertheless gained the favor of Constantine and won many new adherents. After his death (336) the movement spread more rapidly than before. When Constantine died in 337, the empire was divided among his three sons, two of whom, Constantine and Constantius in the West, accepted the Nicene creed, while Constantius in the East was a decided favorer of Arianism. An anti-Nicene council at Antioch (341), consisting of 90 bishops, issued decrees on the ground of which Athanasius, who in 338 had returned from exile to his diocese, was again deposed. In the West, on the contrary, a synod at Rome in 343 declared Athanasius innocent of the charges preferred against him and the authors of his exile heretics. In order to put an end to this conflict, Constantius and Constantius (Constantine had died in 340) convoked the general synod of Sardica in Lower Mæsia in 343 or 344 (not, as has heretofore been generally assumed, in 347). The Arians, having a minority of the 176 bishops present, held a council of their own, at first in the imperial palace in Sardica, and subsequently at Philippopolis. Each party anathematized the other; but the Nicæans triumphed. Constantius so far yielded to the remonstrances of Constantius as to allow the return of Athanasius (349); but when he became soon after sole ruler of the empire, his influence at the synods of Arles (353) and Milan (355) secured the condemnation of Athanasius and the adoption of Arian decrees. Pope Liberius and several bishops, among them Athanasius, were banished, and Arianism was completely successful. The sect now became divided into

strict and moderate Arians. Eusebius of Cæsarea declared the Son to be *homoiousios* or similar in substance to the Father, and his followers were called Homoiousians or Semi-Arians. In opposition to him, Eusebius of Nicomedia showed himself an uncompromising Arian. When the emperor attempted to enforce the Arian resolutions of Milan in the place of those of Nice, the strict Arians, under the leadership of Aëtius, deacon at Antioch, and Eunomius, bishop of Cyzicus in Mysia, attacked the Semi-Arians as well as the Nicene doctrine as illogical, and developed in opposition to it a strict subordinationism. The reputation of Eunomius in his party was so great, that their original name of Aëtians gradually gave way to that of Eunomians. They were also called Anomœans, Heterousiasts, and Exeucontians, as they maintained that the Son was dissimilar to God (*ἀνόμοιος*), of different essence (*ἐτέρας οὐσίας*), and created out of nothing (*ἐξ ὀνκ ὄντων*). Several synods were held for the purpose of healing these divisions. At the second great synod of Sirmium (357) a confession of faith was adopted, to which not only the strict Arians, but even the Nicene bishops, including their leader Osius of Corduba, subscribed. But the confusion became greater than ever. An Arian synod at Antioch (358) condemned, while a Semi-Arian synod at Ancyra (358) approved the expression *homoiousios*. At the third synod of Sirmium (359) Pope Liberius subscribed to a Semi-Arian declaration in order to obtain permission to return from Constantinople to Rome. The Semi-Arians seemed to be in the ascendancy; the emperor is said to have exiled no fewer than 70 strict Arians, and Bishop Marcus of Arethusa was instructed to draw up a new confession of faith, the fourth Sirmian formula, which avoided the word *ousias* and affirmed that the Son was similar in everything to the Father. In order to reunite the whole church on this platform, Constantius wished to call an œcumenical council; but the influence of the Arians caused the convocation of two synods, an eastern one at Seleucia, and a western at Rimini. At the former there were present 105 Semi-Arians, 40 strict Arians, and 10 Nicæans; at Rimini the Nicæans had a majority. Both synods condemned the strict Arians, who however succeeded in regaining the favor of the emperor. Threats induced nearly all the bishops of both synods to subscribe to a strict Arian creed, although the most offensive party expressions were studiously avoided, and even a few of the uncompromising leaders of the party, as Aëtius, sent into exile. Thus Arianism was looked upon as the official creed of the majority of Christian bishops. But its ascendancy was of short duration. On the death of Constantius (361) and the accession of Julian the Apostate, the bishops of all parties were allowed to return to their sees, and soon the Nicene party reëstablished themselves in Egypt under Athanasius, and in Gaul, Spain,

and Greece. Pope Liberius ratified the anti-Arian resolutions passed in 362 by the synod held in Alexandria, and soon the Nicene creed was predominant throughout the western countries. In the East, Arianism found a zealous supporter in the emperor Valens (364-378), and the violent measures which were adopted against both the Niceneans and the Semi-Arians induced a portion of the latter (366) to submit to the Nicene creed. With the death of Valens (378) Arianism began to decline. The emperor Gratian issued an edict of toleration (378), which allowed the exiled bishops to return and greatly strengthened the Nicene party. In 379 Gratian shared the empire with Theodosius, who the next year issued an edict threatening all heretics with the heaviest penalties, and as soon as he arrived in Constantinople took from the Arians all their churches. In 381 he convened the second œcumenical council at Constantinople, which anathematized the Arians. In another synod held at Constantinople in 383, Eunomius presented his confession of faith, which is still extant. As the Arian leaders refused to submit, still more rigorous decrees were issued, to which they appear to have soon succumbed, for the last trace of them in the eastern empire ceased under the reign of Arcadius, the son of Theodosius. In Italy the empress Justina, while regent for her minor son Valentinian II., favored the Arians; but Ambrose, the great bishop of Milan, successfully thwarted her plans, and at the synod of Aquileia (September, 381) caused the Arians to be anathematized and deposed. Moreover, the reign of Justina was too short to be of real service to the dying sect.—Crushed out in the Roman empire, Arianism for several centuries remained the religion of the Germanic tribes. The Ostrogoths professed Arianism, but without persecuting the Catholic church, until their power was lost in 553. The Visigoths were more intolerant, but in 589, by order of their king Reccared, they joined the Catholic church at the council of Toledo. The Arian Vandals, after conquering Africa under Genseric (429), began a most cruel persecution of the Catholics, which did not cease until the destruction of their empire by Belisarius (534). The Suevi in Spain adopted the Arian form of Christianity toward the middle of the 5th century; about 558 they joined the Roman communion. The Burgundians, who had come to Gaul as pagans (407), appear in 450 as Arians. The Catholic church became predominant among them under King Sigismund (517), whom Bishop Avitus of Vienne had won over to the orthodox creed. The last refuge of Arianism was with the Lombards, who entered Italy as Arians in 568. The Catholic church gained a footing among them through the wife of King Autharis, the Bavarian princess Theodelinda; and under her second husband Agilulph and her son Adelwald the Catholics obtained possession of most of the churches. A reaction

followed when an Arian ascended the throne; but he was unable to suppress Catholicism, and for a time every important town had a Catholic and an Arian bishop. Under Liutprand (died 744) Arianism as a sect became extinct. As a theological opinion, however, it often reappeared, and after the reformation of the 16th century was regarded by more than one religious denomination as the true doctrine of the person of Christ. In the church of England Arian views found learned champions in Professor Whiston and Dr. Samuel Clarke.—The works of the Arian writers are mostly lost; we still possess, however, the writings of Eusebius of Cesarea, who ranks among the ablest defenders of the ancient system, and fragments of the church history of Philostorgius. Histories of Arianism have been written by Maimbourg (*Histoire de l'Arianisme*, Paris, 1682) and J. A. Stark (*Versuch einer Geschichte des Arianismus*, Berlin, 1783); but the best source of information on the controversial aspect of the question is Baur's *Geschichte der christlichen Dreieinigkei* (Tübingen, 1841-'3); while the history of the sect is nowhere treated of so fully as in Hefele's *Concilien-geschichte* (vols. i. and ii., Tübingen, 1855). See also Revillon, *De l'Arianisme des peuples germaniques* (Paris, 1850).

ARIANO, a town of southern Italy, in the province of Principato Ultra, 15 m. E. N. E. of Benevento; pop. about 12,000. It is built upon a steep hill, in one of the most frequented passes of the Apennines, and many of the poorer dwellings are dug into the rock and earth. It contains a fine cathedral, numerous churches and convents, several *monts de piété*, and an academy. This town has frequently been visited by terrible earthquakes, the last of which happened in 1732.

ARIAS MONTANUS, **Benedictus** (BENITO ARIAS MONTANO), a Spanish ecclesiastic and oriental scholar, born in a village of Estremadura in 1527, died in Seville in 1598. Philip II. sent him to Antwerp in 1568, to superintend the publication of the magnificent edition of the "Polyglot Bible," to be prepared in that city. The task employed him for four years, and he was rewarded with a pension of 2,000 ducats and a royal chaplaincy, refusing a bishopric. His works, which are numerous, are principally on Hebrew antiquities. He was an unyielding enemy of the Jesuits.

ARICA, a seaport town of Peru, in a province of the same name, department of Moquegua, in lat. 18° 26' S., lon. 76° 24' W., 640 m. S. E. of Lima, and 30 m. S. of Tacna, with which it is connected by railroad. It has been the theatre of many destructive earthquakes, one of the worst of which occurred Aug. 13 and 14, 1868, involving the loss of 500 lives and \$12,000,000 worth of property. Not a building was left uninjured. The shocks were followed by a tidal wave in which the United States storeship *Fredonia* was wrecked with the loss of all lands, and the United States steamer *Wateree* and

other vessels were carried ashore and stranded. The fortified island of Alaeran, which defends the port of Arica, was submerged three times, all the garrison perishing. The first wave, which rose to about 40 feet, was succeeded by three or four others of less height. The shocks occurred on the first day every quarter of an hour, and on the second day every hour. Among the curious effects of the earthquake in the vicinity of Arica was the opening of the earth, and the disclosure of a large number of mummies, which had been buried in the sand in a sitting posture, facing the sea, in a cemetery covering a large area.

ARIÈGE, a southern department of France, formed chiefly of the old territory of Foix, and named after the Ariège river, which, rising in the eastern Pyrenees, flows N. N. W., and empties into the Garonne, after a course of 90 miles. It is bounded by the departments of Haute-Garonne, Aude, and Pyrénées-Orientales, and the Pyrenees mountains; area, 1,889 sq. m.; pop. in 1872, 246,298. The department lies principally on the northern slope of the Pyrenees, and some of the mountains on the southern border rise to an altitude of 9,000 and 10,000 feet. It contains valuable iron mines, the ore being in some places auriferous, and large quarries of marble, freestone, plaster, and slate. The Ariège carries gold sand, whence its ancient name, Aurigera. On the highlands are meadows, where cattle and merino sheep are raised in large numbers. The forests furnish good timber. Bears, wild boars, wolves, foxes, chamois, and deer are abundant. The lowlands are tolerably fertile and well cultivated, producing wheat, rye, oats, maize, millet, hemp, flax, and fruits of various kinds. Vineyards, to the extent of 5,000 acres, yield a wine of inferior quality, all of which is consumed at home. The working of metals is the principal branch of manufacturing industry; but there are saw mills and paper mills, and manufactories of cloth, hosiery, linen, and soap. It is divided into the arrondissements of Foix, St. Girons, and Pamiers. Capital, Foix.

ARIEL, a Hebrew word, signifying "lion of God," occurs as a personal name in the Old Testament, as well as a poetical designation of the altar of burnt offerings (Ezek. xliii.), and, according to general interpretation, of the city of Jerusalem (Isa. xxix.). Among the Jews of a later period, the name was, in cabalistic parlance, given to a water demon.

ARION, a musician of Lesbos, the reputed inventor of dithyrambic poetry, was a friend of Periander, the ruler of Corinth (about 600 B. C.). Having spent some time in Sicily and Italy, he amassed great wealth by his playing on the cithara, in which he excelled all his contemporaries. On a voyage from Tarentum to Corinth the sailors determined to throw him overboard and seize his treasures. Discovering the plot, he begged permission to play one melodious tune before it was put in execution, and, having done so,

threw himself into the sea. The dolphins, charmed by his music, carried him on their backs to Tienarus, whence he passed over to Corinth, and on the arrival of the ship Periander had the sailors put to death.

ARIOSTO, Ludovico, an Italian poet, born in Reggio, near Modena, Sept. 8, 1474, died in Ferrara, June 6, 1533. His father was a member of the highest tribunal of Ferrara, and a friend of the duke. Ludovico was the eldest of ten children. He manifested even when a boy great ability in composition, and wrote several little comedies of some merit. At his father's wish he undertook the study of the law, though the profession was most irksome to him. After five years of study he abandoned the trial and devoted himself entirely to literature. He read the best Latin authors, under the tuition of Gregorio da Spoleto, with such assiduity that he soon became an accomplished Latinist. From ideas suggested by Plautus and Terence he wrote two dramas, *La cassaria* and *I suppositi*. His lyric poems were much admired by Cardinal Ippolito d'Este, son of Duke Ercole I. of Ferrara; and in 1503 the cardinal took him permanently into his service, and intrusted him with many important affairs, allowing him a small pension. A few years after this Ariosto began his poem of *Orlando furioso*, the composition of which occupied him for ten years or more. At the age of 24 he had become by his father's death the sole guardian and support of his nine brothers and sisters. He was obliged to fulfil the duties of a courtier and to obey the constant and petty exactions of his patron, to undertake now and then an embassy or a journey, and to take charge of much of the business correspondence of the cardinal. But while discharging all his duties faithfully, he worked constantly at his poem, and was rewarded, on its publication in 1516, by almost immediate fame. Only his patron, whom he had extravagantly praised in it, treated the work with contempt; and soon after its publication he dismissed Ariosto from his service because the poet refused on account of his health to go with him to Hungary. He soon afterward entered the service of the cardinal's brother Alfonso, then reigning duke, who treated him with generosity, but conferred upon him afterward what seemed a most inappropriate honor, in appointing him governor of the district of Carfagnana, which was everywhere infested by banditti. With unlooked-for ability in this new sphere, Ariosto soon restored order, and after three years returned to Ferrara and established himself in a pleasant home. He repeatedly revised the *Orlando*, making of it 46 cantos instead of the original 40, and greatly changing the whole. During the last years of his life he also wrote comedies and satires. The large theatre built by the duke for the performance of Ariosto's comedies was burned in 1532. The poem of *Orlando furioso* is in part of its plot almost a sequel to the *Orlando innamorata* of Boiardo,

but the lesser poem did little more than suggest the greater. The *Orlando* is a fantastic story, involving a thousand interwoven episodes besides the plot from which it takes its name—a plot which follows the fortunes of Orlando made mad by love of Angelica; but so rich was its author's fancy and so bright his narrative, that even now the poem stands in Italy at the head of all poems of chivalry. It has been translated into almost every language. The principal ancient editions of the *Orlando furioso* are those of Ferrara, 1516, 1524, and 1532, published under the superintendence of the author, and the Aldine edition of 1545. The best modern edition is that of Morali (4to, Milan, 1818), which follows the original text of 1532. Of the English translations by Harrington, Hoole, and Rose, the last is by far the best.

ARIOVISTUS, a chief of the Marcomanni, a German tribe, crossed the Rhine with 15,000 warriors at the call of the Sequani, who were oppressed by the Ædui, defeated the Ædui in 72 B. C., but took one third of the land of his allies, invited his countrymen over the Rhine, and made a settlement there of 120,000 Germans, belonging to several tribes. The Ædui and Sequani called in Julius Cæsar and the Romans to their aid. Cæsar ordered Ariovistus to make no more conquests, to call no more Germans over, and to give up the hostages he held of the Gauls. Ariovistus returned an insolent reply. Cæsar marched against him and compelled him to give battle near Vesontium (now Besançon) in 58. He was defeated, and few of his warriors escaped. He himself crossed the Rhine in a small boat, and ended his days in obscurity.

ARISTA, Mariano, a Mexican general, born in the state of San Luis Potosí, Mexico, July 16, 1802, died in Spain, Aug. 9, 1855. Having distinguished himself in the successive wars which established first the independence of Mexico and afterward the republican form of government, he attained a high position in the Mexican army, and in 1836 was second in command to Santa Anna, then general in chief. By the revolutions which continually agitated Mexico he was twice deprived of his command; but his military knowledge was indispensable to every dominant party, and he was quickly restored and promoted. In the war with the United States he commanded at Palo Alto and Resaca de la Palma; and after its close was appointed in June, 1848, minister of war under President Herrera. In 1850 he was elected president of Mexico, but resigned Jan. 6, 1853, and retired to his farm, and was banished soon afterward.

ARISTEUS, in Greek mythology, son of Apollo and Cyrene, and father of Actæon. He fell in love with Eurydice, the wife of Orpheus, whom he pursued into the fields, where she was bitten by a serpent. For this he incurred the anger of the gods. He taught men the culture of the olive and the management

of bees, and was extensively worshipped in Greece and the Grecian islands as protector of pastoral life and husbandry.

ARISTARCHUS, I. An ancient grammarian and critic, born in Samothrace, flourished in the 2d century B. C. He was educated at Alexandria in the school of Aristophanes of Byzantium, and founded a critical school, which long flourished at Alexandria, Rome, and elsewhere. Alexandria and Rome alone contained at one time no fewer than 40 celebrated grammarians who had been brought up in his academy. He was the preceptor of Ptolemy Epiphanes and Ptolemy Phiseon. In his old age he went to Cyprus, and being afflicted with dropsy, he put an end to his life by voluntary starvation, in his 72d year. Aristarchus is said to have written 800 commentaries on the text of the great Greek poets; but he devoted his chief labor to Homer, whose present text is based upon that adopted by him. Nothing remains of all his writings save scattered fragments. **II.** Of Samos, a Greek astronomer, flourished about 270 B. C. He was one of the first who held that the earth revolves around the sun, for which opinion some thought him guilty of impiety. The only work of his extant is a treatise on the distance and magnitude of the sun and moon, of which the original was published by Wallis in 1688, and a French translation in 1810.

ARISTIDES, I. An Athenian statesman, called the Just, died probably in 468 B. C. Of his early life little is positively known. He was one of the ten leaders of the Athenians at the time of the Persian invasion under Darius, and before the battle of Marathon persuaded the other generals to follow his example in giving up the chief command to Miltiades, instead of each claiming it for one day, as was allowed by law. This united action insured the success of the battle. The year after Marathon (489) he was appointed archon, but a few years later, by the intrigues of his rival Themistocles, he was ostracized on the pretext that he was acquiring an influence dangerous in a democracy. He employed the period of his exile in endeavoring to stir up the Grecian cities to resist the Persians, at that time preparing for a second invasion. He sought an interview with Themistocles before the battle of Salamis (480), concerted with him the plan of that engagement, and gave him his hearty support. The success of the Greeks at Plataea (479), where he commanded under Pausanias, was chiefly owing to his courage and watchfulness. The Persian war continuing, he, with Cimon, the son of Miltiades, was sent at the head of the Athenian forces to join the confederate army. When the Ionian states, disgusted with the arrogance of Pausanias, decided to form a confederation under the hegemony of Athens, Aristides was appointed to adjust the relations of the various parties to the arrangement, and to assess the expenses of the war on the several states—a commission which he executed to the

satisfaction of all. When Themistocles fell under suspicion he did not join in the prosecution; and after the banishment of his rival he always spoke of him with admiration and respect. He died so poor that he was buried at the public cost; his daughters received dowries out of the public treasury, and a landed estate was bestowed on his son. **II. Ælius**, a Greek rhetorician, born at Hadriani in Bithynia, A. D. 117 or 129, died about 180. He was the son of Eudemon, a priest of Jupiter. After travelling through the countries which border the Mediterranean, and as far as Ethiopia, he took up his abode at Smyrna; and when that city was almost destroyed by an earthquake in 178, he persuaded his friend the emperor Marcus Aurelius to assist in rebuilding it. For this Aristides was named the founder of the city, and a bronze statue was raised to him in the agora. Fifty-five of his orations and declamations have been preserved, consisting of eulogies on various divinities, panegyrics on towns, and treatises on rhetorical topics. In his "Sacred Discourses," where Aristides describes a singular malady, not unlike somnambulism, the disciples of mesmerism find something similar to the mesmeric phenomena. A statue discovered in the 16th century, representing Aristides in a sitting posture, is now in the museum of the Vatican. The best complete edition of his works is that of Dindorf (3 vols., Leipsic, 1829). **III.** Of Thebes, a Greek painter, flourished from about 360 to 330 B. C. He is said by Pliny to have been a little older than his contemporary Apelles, and to have been the first who expressed upon the countenance the passions of the soul. At the time of the Roman conquest (146 B. C.), the consul Mummius, discovering the high price set upon a battle picture by Aristides, seized it and sent it to Rome. It was placed in the temple of Ceres, and is said to have been the first foreign painting exposed to the view of the Romans.

ARISTIPPUS, a Greek philosopher, disciple of Socrates, born in Cyrene, flourished about 380 B. C. He was luxurious, sensual, and avaricious, and prided himself on extracting pleasure from both prosperity and adversity, and controlling them alike. His conversation was witty and agreeable. He is said to have incurred the dislike of Plato and Xenophon, who accordingly speak of him slightly. He spent a part of his life at the court of Dionysius the Elder of Syracuse. His doctrine, called from his birthplace the Cyrenaic philosophy, was reduced to a system by his grandson, Aristippus the younger. It pronounces pleasure the chief good, and pain the chief evil—the former a moderate, the latter a violent motion of the soul. Pleasures differ only in their degree of purity. Actions are to be judged good or bad by their results; and in forming a judgment the only authorities are law and custom. Whatever conduces to pleasure is accounted virtue; but virtue is regarded as a quality of mind rather than of the body, since

bodily pleasure is valued for the sake of the mental state it produces. A subject becomes cognizant of objects only through the medium of impressions; the only existences are states of mind; and man is the measure of all things.

ARISTOBULUS. I. A Jewish writer of Alexandria, who flourished under Ptolemy Philometor, about 160 B. C. He wrote philosophical commentaries upon the Pentateuch, composed in the purest Greek, in which he undertook to prove that the most ancient Grecian poets, historians, and philosophers were acquainted with the sacred writings, and in the habit of borrowing largely from them. In support of this theory, he forged numerous passages, ostensibly from Musæus, Linus, Homer, and others, with such art as to deceive Greek writers, and also some of the fathers of the church, who speak of him as a Peripatetic philosopher, the founder of Jewish philosophy in Egypt. Of his writings only scanty fragments have been preserved. **II.** The eldest son and successor of John Hyrcanus, the Asmonean ruler of Judea, and the first of that house who assumed the royal title. His reign lasted only one year (106–105 B. C.). According to his father's will he was to act only as high priest, with the title of *nasi* (prince), and his mother to carry on the affairs of state. Impatient to rule, he threw his mother into a dungeon, where she perished of hunger, imprisoned three of his four brothers, and proclaimed himself king. The queen, Salome or Alexandra, persuaded Aristobulus that his remaining brother Antigonus meditated treason and usurpation, and he was cut down by the royal guards. Aristobulus, who was sick, grew worse from remorse and vomited blood, which, being carried off by a domestic, was spilled on the very spot on which the blood of Antigonus had been shed. The parricide saw in the accident a sign of the vengeance of Heaven, and soon after expired in terrible agony. **III.** Son of Alexander Jannæus, the brother and successor of the preceding. His history can be properly treated only in connection with that of other persons. (See HEBREWS.)

ARISTOCITON. See HARMODIUS AND ARISTOCITON.

ARISTOMENES, a Messenian general and statesman, the hero of the second Messenian war, of the royal line of Ægyptus. The Messenians, having determined to free themselves from the tyranny of their Spartan conquerors, selected him as their chief. He formed an alliance with Argos, Elis, Sicyon, Arcadia, and Pisa; but before the troops they promised him could arrive, he began the war by the decisive battle of Deræ, 685 B. C. His exploits in this conflict induced his countrymen to offer him the throne of Messenia, but he refused it. In the same year he entered Sparta alone, by night, and fastened a shield with a taunting inscription to the temple of Minerva. During the next year he won great victories at the Boar's Pillar (*κάπρον σήμα*) in the plain of Stenyclerus, and at Phæra, which latter place

he sacked. But in 682, betrayed by his ally Aristocrates of Arcadia, who deserted him in the midst of the fight, he was utterly defeated, his army almost destroyed, and he himself compelled to take refuge in the mountains with his few remaining troops. Here he continued the war with great pertinacity for 11 years. Having been captured by the Spartans in one of his incursions, he was thrown into a cavern into which malefactors were cast; but he was uninjured by the fall, and escaped by following a fox through a passage leading from the cave. Again captured, he escaped by the aid of a young girl. He twice offered to Zeus the *hekatombonia*, or sacrifice prescribed for one who had slain with his own hands 100 enemies in battle. At last the Spartans surprised at night his fortress of Ira, in the mountains; but even then they encountered such a resistance that they were obliged to consent to his terms, which permitted him and his followers to retire unmolested. Soon after this he formed a new plan of attack on Sparta; but for the second time he was betrayed by Aristocrates, who was killed for his treachery. The countrymen of Aristomenes were now exhausted, and their army was too small to continue the war. Many of them, under the hero's two sons, went to Rhegium and formed a colony there. Aristomenes went to Rhodes, where one of the reigning princes had married his daughter, and there ended his life peacefully.

ARISTOPHANES, the only writer of comedy in ancient Greece any of whose entire works are still extant, probably born between 450 and 444 B. C., died not later than 380. Very little is known of his life outside of his literary work, the only sources of information being allusions of contemporaries, passages in his plays, and a very unsatisfactory biography by an unknown ancient author. He was an Athenian of the tribe Pandionis, the son of a certain Philippus or Philippides; though traditions, probably having their origin in the attempts of his enemies to deprive him of the privileges of a native Athenian citizen, speak of him as born in Rhodes, others in Egypt, Camirus, or Nanceratis. He seems to have appeared as a comic poet in the fourth year of the Peloponnesian war (427). A clue to the time of his birth is found in the fact that at this time he was too young to compete for a prize, and that his first comedy, "The Banqueters," was therefore produced under the name of another. In 426 he produced "The Babylonians;" in 425 "The Acharnians," still extant, which, put in competition in the name of Callistratus, won the first prize. In some passages of these earliest works he had satirized Cleon, the Athenian demagogue, and the latter avenged himself by making the first of those attempts noticed above to prove that Aristophanes was of foreign birth. This attempt was afterward twice repeated, but each time the poet successfully repelled the charge. In 424 he attacked Cleon with unsparing sat-

ire in the famous comedy of "The Knights;" and finding no actor brave enough to take the part of the demagogue, then at the height of his popularity, Aristophanes played the rôle himself, with his face smeared with lees of wine; for no one dared even to make a mask representing Cleon. His plays now appeared in rapid succession. Of the 54 which we are told he wrote, we possess 11, which, besides "The Acharnians" and "Knights" already mentioned, are as follows: "The Clouds," produced in 423 B. C., directed against the Sophists and their leader Socrates; "The Wasps," 422, an attack on the corruption of the courts; "The Peace," 419, written to point out the evils wrought by the Peloponnesian war; "The Birds," 414, to ridicule the Sicilian expedition; "Lysistrata," 411, a further picture of the evils brought about by the Peloponnesian war; "Thesmophoriazuse," probably in the same year, an attack on Euripides; "Plutus," 408, ridiculing the imitation of Dorian fashions which prevailed at the time of its production; "The Frogs," 405, a second satirical attack on Euripides; "Ecclesiazuse," 392, a play with the same aim as "Plutus." Of the comedies of Aristophanes it is excessively difficult for a modern reader to form anything approaching to an accurate judgment. His wit is expended on topics so purely local, that it requires the closest acquaintance with the occurrences and characters of the day, the temper of the people, and the every-day circumstances of Athenian life, to enable a person to appreciate and enjoy his humor. His style and versification are among the best examples left us of a complete mastery of the Attic dialect. In general, the persons and things which Aristophanes attacked were worthy of condemnation. Where a prominent exception to this statement is found in the case of Socrates, he probably only seized upon the natural temptations offered to a satirist by the philosopher's notoriety and eccentricities; and it seems most improbable that he acted, as many have thought, in collusion with the future accusers of the great Sophist.—Among the best editions of Aristophanes are those of Küster and Brunck, and that of Invernizzi, completed by Beck and Dindorf; besides some editions of separate plays of rare excellence by Mitchell, who has also ably translated some of the number, and by Prof. Felton of Harvard university. An admirable translation of five plays was made by John Hookham Frere while in Malta, which were first printed for private circulation, but are now contained in the collective edition of his "Works" (London, 1872).

ARISTOTLE (Gr. Ἀριστοτέλης), perhaps the greatest ancient philosopher, founder of the school of Peripatetics, born in Stagira, a Greek colony of Macedonia, near the mouth of the Strymon, in 384 B. C., died at Chalcis, on the island of Eubœa, in 322. From his birthplace he was called "the Stagirite." He studied for a short time at Atarneus in Asia Minor, and at

17 years of age went to pursue his studies in Athens, where he resided for 20 years. He was a pupil of Plato, whom he sincerely admired, though opposed to him in philosophy. Plato was accustomed to call him, on account of his enthusiasm for knowledge and his restless industry, the "intellect of his school." About 343 B. C. Philip of Macedon made him the teacher of his son Alexander, at that time 13 years old. His influence on Alexander and Philip was for many years very great and salutary, and Philip rebuilt at his request the city of Stagira, which had been destroyed, and erected there, in a pleasant grove, a school called Nymphæum, where Aristotle was to teach. Alexander after the conquest of the Persian kingdom presented him with 800 talents, or nearly a million of dollars. He also sent to him whatever he discovered on his marches that was unknown in Greece, such as plants and animals for scientific examination, and is said to have been accompanied by him in several of his expeditions. Aristotle returned to Athens in 335, or, according to Ammonius, in 331, bringing with him his scientific collections, and established a new school of philosophy in the Lyceum, a gymnasium near the city. In the forenoon he instructed his intimate pupils in a philosophical way, which lectures were called esoteric; and in the evening he taught a large popular circle about plainer matters, in what were called exoteric or public lectures. His philosophical school is called the Peripatetic, because he taught while walking up and down (*περιπατών*), or from the shady walks (*περίπατοι*) around the Lyceum in which he delivered his lectures, and which in the time of Plutarch were still pointed out to the traveller. His friendly relations with Alexander were at length interrupted, perhaps on account of admonitions which he sent to that conqueror when, in his later years, he precipitated himself into a dissolute life. Yet the Athenians suspected him of partisanship for Macedonia, accused him of impiety, and forced him to flee to Chalcis, where he died.—Only a part of his numerous writings on almost every branch of science and art were then published; of the remainder many were lost, and many published only in the first centuries of the Christian era. The most important of them bear the following titles: "Organon" or "Logic," "Rhetoric," "Poetics," "Ethics," "Politics," "History of Animals," "Physics," "Metaphysics," "Psychology," and "Meteorology." His writings on mathematics, economy, and history are lost, as well as his letters, and a work called *Politiæ*, which contained 158 ancient state constitutions and legislations. Many books bearing his name are spurious, and it is only in the present century that the spurious begin to be sifted from the genuine. His style is difficult to understand, not only because of the intricacy of the subjects, but also on account of the technical terms entirely his own. No other philosopher has exerted

so large an influence on so many centuries, and on the ideas of so many nations, as Aristotle. His merits as a metaphysical thinker may perhaps be variously estimated, but his performances in natural science, which he first created, and his method of philosophy, constitute his greatness. He was the first careful observer, dissector, and describer of animals. He first divided the animal kingdom into classes; described a great many animals before unknown to the scientific world; came near discovering the circulation of the blood; discriminated between the several faculties, the nourishing, feeling, concupiscent, moving, and reasoning powers of animal organism, and attempted to explain the origin of these powers within the body; and built his moral and political philosophy on the peculiarities of human organization. His philosophical method consists in the principle that all our thinking must be founded on the observation of facts. Logic is the fundamental science, and the principles which he laid down for it have never been superseded. It is acknowledged by Kant and Hegel, the two most profound thinkers of Germany, that from the time of Aristotle to their own age logic had made no progress. He invented the categories, or fundamental forms of thought, universal expressions for the ever-changing relations of things, and limited their number to ten; and he devised the so-called "syllogistics," or science of forming correct conclusions. He likewise became the father of modern psychology, showing how the mind creates its speculative methods and general notions; and that though we cannot prove their correspondence with the reality, because there is no direct proof for things which transcend our senses and observation, yet we are always compelled to recur to these general notions and take them for indispensable forms of thinking, if we will think at all. Every science must, according to Aristotle, have a fundamental principle, which need not and cannot be logically proved, because it is in itself certain, and accepted as manifest truth. Aristotle first discriminated between the substance of things and their accidental peculiarities, and created the philosophical notions of "matter" and of "form." He also established the philosophical notions of "space" and "time," and showed their connection with matter, while he first furnished the world with what is commonly called the cosmological argument for the existence of God. He states it thus: Although every single movement and existence in the world has a finite cause, and every such finite cause another finite cause back of it, yet back of this infinite series of finite causes there must be an infinite immaterial being, a first something, unmoved, all-moving, pure energy, absolute reason, God. In psychology and anthropology, Aristotle is the author of the theory of different powers of the soul, of distinct feeling, willing, reasoning, and moving powers or faculties. The reasoning power is

regarded by Aristotle not as a product of the body, but as bestowed on it from outside, and as perfect only after its separation from the body by death. Proceeding from the principle that whatever is to be the goal and highest good of humanity must not depend on casualities and ever-changing minor circumstances, but must be certain in itself, and impart to every other good its value, he maintains that the *eudaimonia*, or highest possible pleasure which is conceivable for man, is derived only from the perfect satisfaction of those faculties which distinguish him from the beasts, that is, of the reasoning powers.—Of his earliest pupils and followers, none but Theophrastus, and he not strictly a philosopher is worth mentioning. The age after Aristotle's death was not favorable to purely speculative philosophy. For three centuries Stoicism and Epicureanism took the place of his philosophy in the favor of the educated world; and these were succeeded by Neo-Platonism. Later the philosophy of Aristotle was rendered obnoxious to the fathers of the church by the pagan tendencies of its expounders at Alexandria, but a few, like Boëthius, ventured to defend his views. Up to the 11th century Aristotle was almost unknown to the Christian world, but he was a favorite with the Arabians of the 8th, 9th, 10th, and 11th centuries. Through the Arabians, the scholastic writers of the 11th century made acquaintance with his "Physics" and "Metaphysics," though by means of very imperfect translations; his "Logic" they had, though not extensively, known before. From that time Aristotle, though sometimes disparaged as a heretic, remained for four centuries the authority of the Christian world in all matters not strictly pertaining to dogmas. In the 11th century the dispute between the nominalists and realists began to divide theologians; the realists asserting with Plato that our general notions, called *universalia*, are the substance of things, that our ideas answer not only to the reality of objects, but contain their soul and life; the nominalists, in the name of Aristotle, maintaining that these general notions are mere abstractions, inventions of the brain, not expressing the real substance of things. From the exposition that we have given, it appears that this pretended Aristotelianism was a misunderstanding of Aristotle's philosophy, which, though it admits on the one hand that our general notions cannot be demonstrated to express the full substance of things, yet at the same time asserts that they are indispensable for every purpose of thinking. After the restoration of classical literature in the 15th century, his writings were extensively published, and his philosophy began to be better understood; and it has been further developed by Bacon, Descartes, Spinoza, and Kant. Fichte, Schelling, and Hegel opposed it, though the latter adopted many of its ideas. It is, however, not so much by his philosophical system that Aristotle has wielded his enor-

mous influence, especially as this is only now beginning to be fully understood and justly appreciated, as by his logical inventions, and his method of philosophy in general.—The best works on the contents, spirit, and bearings of the writings of Aristotle are Stahr's *Aristotelia* (2 vols., Halle, 1830); Franz Biese's *Philosophie des Aristoteles* (2 vols., Berlin, 1835-'42); and "Aristotle," a posthumous work, by George Grote (London, 1872). The best complete edition of Aristotle is that of the academy of sciences at Berlin, by Immanuel Bekker (4 vols., Berlin, 1831-'6), with Latin translations and extracts from the old commentaries.

ARISTOXENUS, a Greek writer on philosophy and music, a pupil of Aristotle, born at Tarentum, Italy, flourished about 320 B. C. According to Suidas, he published 450 works on all imaginable subjects. All these are lost excepting his *Ἀρμονικὰ Στοιχεῖα* ("Principles of Harmony"), published in Latin at Leyden in 1562 by Gogarinus, and in 1616 in Greek by Meursius, and subsequently inserted by Meibom in the *Antiquæ Musicæ Auctores* (2 vols. 4to, Amsterdam, 1652). Aristoxenus's theories of music were opposed to those of Pythagoras, who made music dependent upon mathematics, while the former admitted only the test of the ear.

ARITHMETIC (Gr. *ἀριθμητική*, from *ἀριθμεῖν*, to count), the science of the properties and relations of numbers when expressed with figures or relations of figures. The accepted opinion is that we have derived this science from the Greeks, who obtained it from the Phœnicians; but if we consider that the Chaldeans, one of the oldest nations, have given us the knowledge of certain astronomical cycles or periods, of which the determination required an advanced knowledge of arithmetic, it is evident that its origin is of much earlier date. The Hebrews and Greeks used the first nine letters of their alphabet for the numbers 1 to 9; the next nine letters for 10, 20, &c., to 90; and the others for hundreds; while for thousands they recommenced the alphabet and added to each letter a mark or iota. The Romans followed a similar system, of which our Roman numerals are a specimen. But arithmetic did not reach its more modern state of progress until the introduction of the Arabic figures now used by all civilized nations. The Arabs admit that they obtained these figures from Hindostan in the 10th century. They call them Indian figures, and arithmetic the Indian science. Boëthius, in his work *De Geometria*, informs us that the disciples of Pythagoras used in their calculations nine peculiar figures, while others used the letters of the alphabet; and it is probable that this philosopher, who had travelled considerably, had obtained this knowledge in Hindostan, and communicating it as a secret to his disciples, caused it to remain sterile in their hands. The Greeks in the ordinary way of writing expressed the fractions thus: while β, γ, δ, &c., stood for 2, 3, 4, &c., β', γ', δ', represented $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c. The oldest text book

on arithmetic employing the Arabian or Indian figures, and the decimal system, is undoubtedly that of Avicenna, the Arabian physician, who lived in Bokhara about A. D. 1000; it was found in manuscript in the library at Cairo, Egypt, and contains, besides the rules for addition, subtraction, multiplication, and division, many peculiar properties of numbers. (For a translation of a portion of this remarkable manuscript by Marcel, see De Montfevrier, *Dictionnaire des sciences mathematiques*, vol. i., p. 141 *et seq.*) It was not till the beginning of the 13th century that the science of arithmetic began to be diffused in Europe. One of the earliest writers on the subject was John Halifax, better known as Sacro-Bosco, who in the 13th century composed an arithmetic in Latin rhymes, in which the shapes of the figures are nearly identical with those of the present day. The monk Planudes, who flourished in the early part of the 14th century, wrote a book entitled "Indian Arithmetic, or the Manner of Reckoning after the Indian Style," of which several manuscripts still exist. Contemporary with him was Jordanus of Namur, author of the *Algorithmus Demonstratus*, and also of a treatise on arithmetic which Jacques Faber published with commentaries immediately after the invention of printing. A great development of the science now took place. In the 16th century Clavius and Stifelius (Stiefel) in Germany and Digges in England were conspicuous for their services to this science, and the Arabian or Indian figures came into use among the learned; but it was not till the 17th century that arithmetic began to be a regular branch of common education. —The value of our system of arithmetical notation, as is well known, consists in the adoption of a scale and of a system by which the place of the figure in the order in which it appears causes its value to increase in multiples of that scale. The universally adopted scale is the decimal, probably derived from the number of fingers of the human hand, but other scales might have been adopted as well; and the advantages which some persons suppose might have been derived from the adoption of a different scale, as the duodecimal or twelve, the tonal or sixteen, &c., are more apparent than real. A smaller scale would, however, have simplified arithmetical operations, as was forcibly demonstrated by Leibnitz, who showed how with the smallest possible scale, the binary, and the consequent use of only two figures, 1 and 0, operations were so much simplified that there might be even a saving of time in reducing a decimal expression into a binary one, performing the operation, and restoring it back again into the decimal system. The regular series of numbers, one, two, three, four, five, six, seven, eight, nine, &c., is expressed in the binary system thus: 1, 10, 11, 100, 101, 110, 111, 1000, 1001, &c.; in the ternary system, in which three is adopted as the basis, it is 1, 2, 10, 11, 12, 20, 21, 22, 100, &c.—When arith-

metic goes beyond the practical calculations by numbers, and treats of the properties of numbers in general, it enters the field of algebra. The properties of numbers are of two kinds: some are general and inherent in the numbers themselves, while others depend on the decimal system adopted. Thus the law that the sum of two numbers multiplied by their difference is equal to the difference of their squares is a general property; while the fact that if the sum of the figures is divisible by 9, the whole number is divisible by 9, is a property depending on the adoption of the decimal system; if we had adopted the duodecimal system, 11 would have that property.—Besides ordinary arithmetic, we may distinguish a palpable arithmetic performed by the sense of feeling by the blind; an instrumental arithmetic, where the solutions are obtained by peculiarly contrived instruments; a tabular arithmetic, where problems are solved by means of tables computed for the purpose, &c.—Pestalozzi, the great German pedagogue, applied his method to instruction in arithmetic with the most eminent success. It was introduced into the United States by Warren Colburn of Massachusetts, by the publication of treatises on this subject which have largely influenced the authors of arithmetical text books, a great variety of excellent practical works having since been published, to which we refer for further information in regard to the practical details of this science.—For many curious facts on the properties of numbers, see Gauss, *Disquisitiones Arithmetice*, or Legendre, *Thorie des nombres*.

ARIUS, the founder of Arianism, according to some a Libyan, according to others a native of Alexandria, died in 336. He joined the Meletians in Alexandria, but left them, and in 306 was ordained a deacon by Bishop Peter of Alexandria. He afterward returned to the Meletians and was excommunicated, but was readmitted to the church by Achilles, successor of Peter, and ordained priest. After the death of Achilles, Arius came near being elected bishop of Alexandria; but Alexander was preferred to him. According to the Arian historian Philostorgius, Arius himself brought about the election of Alexander. It is reported that for several years Alexander held Arius in high esteem, and that the most perfect agreement existed between them. The great controversy with which their names are connected began when Alexander made an address to his clergy in which he spoke of the Trinity as consisting of a single essence. Arius exclaimed against this, affirmed the distinct personality of the Father and the Son, and accused Alexander of Sabellianism. Alexander demanded from Arius a recantation; but the latter not only refused this, but sent a written confession of faith to several bishops, requesting, in case they agreed with him, their intercession with Alexander in his behalf. A number of prominent bishops responded favorably; among them were Eusebius of Cæsarea, the church historian, and Eusebius of Nico-

media, who as bishop of the imperial residence had a great influence over Constantine and his sister Constantia. Alexander therefore convened a synod at Alexandria in 320 (or according to some authorities in 321), which was attended by about 100 bishops from Egypt and Libya, at which Arius and his adherents were "expelled from the church which adores the divinity of Christ." As Arius nevertheless continued to teach and to hold divine service, Alexander addressed circular letters to the bishops, in which he asked them not to admit the Arians to the communion of the church, and not to believe Eusebius of Nicomedia and "people of that class." Expelled from Alexandria, Arius went to Palestine, whence he addressed a defence of his doctrine to Eusebius of Nicomedia. Invited to Nicomedia, he wrote thence a letter to Alexander, endeavoring in language as conciliatory as possible to prove his views to be those of the fathers of the church. Here he also wrote his most important work, the *Thalia* ("Banquet"), fragments of which are extant in the writings of Athanasius, and composed several songs designed to make known his principles among the people. A synod held in Bithynia about 323 allowed Arius to hold divine service, and interceded in his behalf with the bishop of Alexandria. The division in the church had now become so great that Constantine was induced to convoke the œcumenical council of Nice in 325, to put an end to the controversy. Arius was present at the council, in which the young deacon Athanasius of Alexandria distinguished himself as the foremost opponent of the Arian views. The council decreed the Son to be consubstantial (*ὁμοούσιος*) with the Father, deposed and condemned Arius, ordered his writings to be burned, and made it a capital offence to own them. The emperor banished Arius to Illyria, and soon the bishops Eusebius of Nicomedia and Theognis of Nice shared the same fate for refusing submission to the decrees of the council. After a time, however, Constantine was induced by his sister and many in his court, who were in sympathy with Arius, to recall and hear him. This was the beginning of new and violent conflicts. In Alexandria the Arians entered into negotiations concerning a union with the Meletians. A synod at Tyre in 335 deposed Athanasius, who was then banished by the emperor to Treves. In 336 Constantine undertook to enforce the recognition of Arius in Constantinople; but on the day fixed for the recognition Arius fell dead in the street. Some of his friends ascribed his death to poison, some of his opponents to the efficacious prayer of the orthodox bishop of Constantinople. (See **ARIANISM**.)

ARIZONA, a territory of the United States, situated between lat. 31° and 37° N. and lon. 109° and 114° 40' W., bounded N. by Utah, E. by New Mexico, S. by Mexico, and W. by California and Nevada; area estimated at 113,000 sq. m. No complete survey of the territory

has been made. It is divided into five counties: Maricopa, Mohave, Pima, Yavapai, and Yuma. Tucson, in Pima county (pop. 3,224), is the capital and largest town in the territory. Arizona City, in Yuma county (pop. 1,144), is a prosperous business place, situated at the junction of the Gila and Colorado rivers. Prescott, the former capital (pop. 668), is situated in central Arizona, and is the headquarters of the military department of Arizona. In 1870 the population of the territory, exclusive of Indians, was 9,658, of whom 3,849 were native and 5,809 foreign born; 1,240 were born in the territory. The total number of Indians was 32,083; of these 4,352 were on reservations and at agencies, and 27,700 were nomadic. Many of these Indians are friendly to the whites, but the greater number are intensely hostile. Of the friendly Indians, the Pimas and the Maricopas rank first in numbers and civilization. They occupy a reservation on the Gila river, about 200 m. E. of Arizona City. The Papagos live S. of the Gila, along the line of Sonora. The Mohaves and the Yumas live along the Colorado, the Utes on the upper Colorado, and the Moquis and Navajos in N. E. Arizona. These tribes are engaged in agriculture and stock-raising. Of the hostile Indians the Apaches are the most powerful and warlike. They comprise several tribes distributed over the greater portion of middle and eastern Arizona; their raids extend all over the territory, with the exception of a narrow strip along the Colorado river and a portion of the lower Gila. Besides the Apaches, the Iualpais or Wallapis, living in the Cerbat range near the Diamond river, and in part of the Aquarius range, are the only dangerous Indians.—The middle and N. E. portions of the territory consist of elevated plateaus from 3,000 to 8,000 ft. above the sea level, with occasional bluffs and volcanic cones rising from 500 to 2,500 ft. above the plateau. The numerous parallel ranges of mountains have a general N. W. and S. E. course, and form long valleys in the same direction. The most marked exceptions to this general direction are the Mogollon range in the east, which extends nearly E. and W. and joins the Sierra Blanca, and an E. and W. range stretching beyond Arizona into New Mexico. The axis of the Black mountains and the Cerbat range, in the N. W. part of the territory, lies very nearly N. and S. The S. portion of the territory is a plain with a slight elevation above the sea, amounting at the mouth of the Gila to only 200 ft. From this plain isolated mountains and mountain ranges rise abruptly. In central Arizona the Sierra Prieta and the Aztec range send foot hills out in every direction, and their flanks sink very gradually to the level of the high plateau surrounding the San Francisco mountain toward the N. E., and to the *mesas* or table lands sloping toward the Colorado on the S. W. The elevation of the town of Prescott is over 6,000 ft. above the sea, while the Tonto and San Francisco plateaus, E. and N. E.

of Prescott, reach an altitude of from 8,000 to 9,000 ft. The San Francisco, a grand volcanic cone, is the highest mountain in Arizona, its summit being over 11,000 ft. above the sea. N. and N. E. of the San Francisco mountains, an immense *mesa*, increasing in altitude toward the Utah line, extends for hundreds of miles. —The largest river of the territory is the Colorado, which is formed by the junction of the Green and Grand rivers in the S. part of Utah, and has a southerly course along the W. boundary of Arizona. It has a very rapid current, and is navigable as far as Callville, 612 m. above its mouth. The cañons formed by the passage of the river through the lofty table lands are unequalled in grandeur. In the Grand cañon of the Colorado the deep and narrow current flows between massive walls that rise to a perpendicular height of nearly 7,000 ft. above the water. The principal tributaries of the Colorado are the Colorado Chiquito, which flows N. W. through the N. part of the territory, the Diamond river, and Bill Williams's Fork, into which flows the Santa Maria. The Gila rises in New Mexico, flows W. through the S. part of Arizona, and joins the Colorado about 180 m. above the gulf of California. It is a very narrow stream with a swift current, shallow during most of the year, but in the rainy season vastly increasing its volume. Its principal tributaries in Arizona are the Salado or Salt river, Verde, San Carlos, Bonito, and Prieto from the north, and Santa Cruz and San Pedro from the south.—Granite, red and white sandstone, limestone, slate, quartz, and metamorphic rocks abound in the mountains. The plains along the lower Gila are entirely made up of quaternary and tertiary deposits, which also form the great Sonora desert S. of that stream. In the Colorado valley, the sedimentary strata consist of quaternary and tertiary gravels and conglomerates, varied in a few localities by a layer of white infusorial earth. The bottom lands consist of calcareous sands and clays, the former predominating. The mountain chains are composed of granites, syenites, porphyries, trachytes, greenstone, basalt, and metamorphic slates. A section of the Grand cañon of the Colorado, 6,800 ft. above the sea level and 5,500 ft. above the river, exhibits the following sedimentary strata down to the underlying granite: upper carboniferous limestone; cross-stratified sandstone; red calcareous sandstone, with gypsum; lower carboniferous limestone; limestones, shales, and grits—Devonian; limestones, mud, rocks, and sandstones—Silurian; Potsdam sandstone; granite. No one of the mineral-bearing territories of the Pacific slope is richer than Arizona, though the mines have not been generally worked. The inaccessibility of the territory (it being off from the great overland lines of travel and without seaports), and the fierceness of the Apaches, have prevented the full development of its mineral wealth. The mountains of southern and central Arizona are nearly all

mineral-bearing, and contain lodes of gold, silver, copper, and lead. The ores of silver found in this region are argentiferous galena, native silver, auriferous sulphuret of silver, black sulphuret of silver, sulphate of silver, sulphate of iron, combined. The ores of copper are usually the sulphurets, principally gray. Nearly all the silver and copper lodes show traces of gold; and placers have been found at many points, but have not proved sufficiently extensive to attract much attention. Gold is found in central Arizona, the ore yielding from \$25 to \$100 per ton. Iron in carbonates and oxides is abundant, and traces of tin and nickel exist. Platinum (metallic) is shown in the placers of the Black cañon. Copper, silver, and quicksilver are found together in a rare combination, but the lode is not large. Lime of a superior quality exists in large quantities near Prescott and Tucson, and is found at other points. Beds of gypsum exist in the San Pedro valley. The salt mountains near Callville and a few miles E. of the Colorado are among the most remarkable formations in Arizona. The deposits of pure, transparent, and beautifully crystallized salt are very extensive, and no salt is superior for table and general use. Traces of coal have been discovered in this locality. The bullion product of Arizona for 1868 was estimated at \$250,000; 1869, \$1,000,000; 1870, \$800,000.—The climate is mild and generally healthful. In southern Arizona the temperature ranges from 34° to 118° F. The atmosphere is dry, and this region is singularly free from malarious diseases. Snow falls in central Arizona, but, excepting in the higher mountains, disappears in a few hours. The temperature in summer rarely exceeds 90°, and seldom falls below zero in winter. Rain falls mainly in the months of July and August, but there are frequent showers in April and May, as well as in the winter months. The average fall of rain in southern Arizona for 1867 was 2.94 inches; 1866, 4.20; 1858, 8.57; 1857, 0.33. The climate of Arizona is said to be highly beneficial to those afflicted with bronchial or lung diseases. According to the census of 1870, the total deaths in the territory for that year were 252, of which 116 resulted from general diseases, 71 from local diseases, 60 from accidents and injuries, and 5 from poisons. Of the local diseases, 44 were diseases of the respiratory system and 15 of the digestive system.—The vegetation of southern and western Arizona is scanty and limited to a few genera, such as cactus, aloe, artemisia, *palo verde*, ironwood, and mesquite, the last a remarkably hard wood. In the middle and N. E. portions of the territory a more varied vegetation prevails. On the hills and mountain sides a rich and abundant pasturage is found. Pine and cedar forests abound; while along the course of the streams ash, walnut, cherry, willow, cottonwood, and many other forest trees grow, and large oak trees are seen on the summits of some of the highest mountains in the Sierra Prieta. The

aridity of the table lands prevents their cultivation; the soil of the valleys is rich, but in places very arid. Where artificial irrigation is practicable, or where there is sufficient moisture, the crops are good, and the cereals yield abundantly. The greater portion of the territory S. of the Gila river is a sterile waste; but the river valleys of this section contain many thousand acres of the most fertile bottom lands, which need only irrigation to make them yield abundant harvests. Indian corn, wheat, barley, oats, grapes, figs, oranges, lemons, sweet potatoes, tomatoes, tobacco, the eastor bean, &c., thrive here wherever the land can be irrigated; there is also much valuable grass land in this section. The valleys of middle and eastern Arizona contain much arable land. Here all the cereals and roots of the northern Atlantic states are grown, while as a grazing country this region cannot be surpassed. A thick growth of gramma and bunch grass covers the whole country, and gives to the pine woods of this region the aspect of beautiful natural parks. Wheat and barley are usually sown from November to February, and harvested in May; the average yield of wheat is from 20 to 40 bushels per acre, and of barley from 30 to 60. After the wheat and barley are harvested, corn can be planted on the same soil with ample time for it to mature. Much of the land of Arizona is cultivated in this way, and produces two crops each year. The average yield of corn is from 30 to 60 bushels per acre. In 1870 there were 14,585 acres of improved land in the territory, producing 27,052 bushels of wheat, 32,041 of corn, and 55,077 of barley; and the estimated value of all farm productions, including betterments and additions to stock, was \$277,998. Cash value of farms, \$161,340; of all live stock, \$143,996; of slaughtered animals, \$9,400.—There are no railroads in Arizona. The Atlantic and Pacific railroad company have obtained a charter with land grants to build a road along and near the 35th parallel to the Pacific ocean; this road has been completed from St. Louis into the Indian territory. A charter and lands have also been granted to the Texas Pacific railroad company to build a road on or near the 32d parallel, from Marshall in Texas to San Diego, California. There is a good wagon road from San Diego, crossing the Colorado river at Arizona City, thence to Tucson and Santa Fé. The last named town is connected with Prescott by a wagon road via Albuquerque. From Prescott to Los Angeles, Cal., there is a wagon road by way of Wickenburg, Ehrenberg, La Paz, and San Bernardino, and also by way of Hardyville and Mohave.—The government is administered by a governor, secretary, treasurer, and auditor, who are appointed by the president of the United States. The legislature and a delegate to congress are elected by the people. The judicial power is vested in a supreme court, consisting of three judges appointed by the president, and probate courts.

The supreme court holds one session annually at Tucson. The salary of the governor and of the judges of the supreme court is \$2,500. In 1870 the assessed value of real estate was \$538,355; personal property, \$871,940; total, \$1,410,295; true value of real and personal property, \$3,440,791; total taxation not national, \$31,323. The internal revenue collections for 1871 amounted to \$16,889.—According to the census of 1870, there were in the territory 1,923 persons between the ages of 6 and 21 years; the number attending school was 149. There were 2,690 persons over 10 years of age unable to read, and 1,934 over 21 years of age unable to write. The legislature has passed a school law levying a tax for school purposes of 10 cents on each \$100 of the taxable property of the territory, and giving authority to the several boards of supervisors of the counties and the boards of trustees of the school districts to levy additional taxes sufficient to maintain a free school in each of the school districts. Four weekly newspapers are published in the territory.—As early as 1526 Don José de Vasconcellos crossed the centre of Arizona toward the Great cañon, and the country was subsequently visited by other Spanish explorers. Numerous ruins of Spanish towns and buildings indicate that here was the seat of an early Spanish colonization, and that the land was highly cultivated. In the N. W. part of the territory, on the Colorado plateau, is a group of pueblos in ruins, containing *estufas*, reservoirs, terraces, aqueducts, and walls of at least four stories high. The most extensive ruins are found in the Gila valley, which is studded throughout with deserted pueblos and remains of irrigating canals, *acquiuis*, pottery, &c. The river banks are covered with ruins of stone houses and regular fortifications, which do not appear to have been inhabited for centuries. The walls are of solid masonry, rectangular in form, and usually two stories high. It is estimated that at least 100,000 people must have occupied the Gila valley at one time.—The territory of Arizona was separated from that of New Mexico and organized by act of congress passed Feb. 24, 1863. The portion N. of the Gila river was obtained by the treaty of Guadalupe Hidalgo, Feb. 2, 1848, while that S. of the Gila was acquired under the treaty made by James Gadsden at Mexico, Dec. 30, 1853. The act of Feb. 24, 1863, creating the territory, describes it as comprising all the United States lands W. of lon. 109° to the California line, which before that time had belonged to the territory of New Mexico. Since then the N. W. corner has been ceded to Nevada. No thorough exploration of central Arizona was attempted until 1862 and 1863, while much of the northern portion has never been explored.

ARJISH or *Erjish Dagh* (anc. *Argamis*), the loftiest mountain of Asia Minor, lying 13 m. S. of Kaisariyeh (anc. *Mazaca Casarea* in Cappadocia), and 117 m. N. by W. from the head of

the bay of Iskanderun. It ascends in an insulated peak to the height of 13,100 ft. It is distinctly visible at a distance of 160 m., and it was believed by the ancients that both the Euxine and the Mediterranean could be seen from its summit. It is an extinct volcano, and its sloping sides are covered with volcanic cones and craters. Its summit is covered with perpetual snow, and the natives of the country affirm that it has never been ascended.

ARK. I. The vessel (Heb. *tebah*) constructed by Noah, according to Gen. vi., for the preservation of his family and of the different species of animals during the deluge. The form of the ark was that of an oblong chest, while its dimensions were 300 cubits in length, 50 in breadth, and 30 in height. Two questions have been raised, with a design to throw discredit on the Biblical account: the first as to the form of the ark, that it was not adapted for floating; the second as to its dimensions, that it was not large enough to answer the purposes for which it was designed. Both to strengthen and to obviate the objections raised, many curious speculations have been resorted to, to prove the basis of calculations, but no valuable results have been attained on either side. **II.** The ark (Heb. *aron*) of the covenant, or testimony, among the appointments of the Jewish tabernacle and temple. This was built of shittim (acacia wood), inlaid and overlaid with pure gold. Its dimensions were two cubits and a half in length, and one and a half in width and height. Its location was in the holy of holies. The cover of this ark was the mercy seat, over which stood the two cherubim. The contents of the ark of the covenant were, according to 1 Kings viii. 9, exclusively the tables of the law received by Moses (from which the ark had its name); but, according to Heb. ix. 4, it also contained the pot of manna and Aaron's rod, and at a later period probably also a copy of the book of the law. The Jews esteemed this ark peculiarly sacred. It was made to be carried in procession before them in the journey to the promised land, and for this purpose was committed to the care of the Kohathites, and none were permitted to touch it but the tribe of Levi. In war times, after the conquest of Palestine, it sometimes accompanied the army. At the close of the judgeship of Eli it was captured by the Philistines, but subsequently restored. It seems to have perished in the destruction of the temple by Nebuchadnezzar.

ARKANSAS, the name given by the Algonquins to the Onquapas, a tribe of Indians of the Dakota family. According to Gravier, a Jesuit missionary in Illinois about the year 1700, the Arkansas had previously resided on the Ohio river, whence after a long struggle they were driven down the Mississippi by the Illinois and their allies. This corresponds with the tradition of the Lenni, another Algonquin tribe, as to the Allegewi or Alleghans; and as early French writers use indifferently the term Al-

kansas or Akansas, the suspicion increases as to their identity. They comprised several divisions known as the Quappas or Kappas, Dogrin-ga, Toriman, and Osottconez or Sothouis. One division, called by the Algonquins Mitchigamias, removed to the country of the Illinois, but subsequently returned. The Arkansas were first visited by Marquette, and from his time were always friendly to the French, welcoming La Salle and Tonti, as well as the survivors of La Salle's last expedition. They refused to join the Natchez against the French, and nearly exterminated the Yazooos, who had massacred the French among them. They were at this time a powerful tribe, able in 1740 to send out 400 warriors, but they soon lost by smallpox and other diseases. The remnant, now called Quappaws, are in the Indian territory west of their former country, and number only 200.

ARKANSAS, a S. W. river of the United States, the largest tributary of the Mississippi except the Missouri. Its extreme sources, which were first explored in 1806 by Lieut. Pike, U. S. A., lie in the Rocky mountains W. of the South Park, in lat. 39° N., lon. 106° W., at an elevation of 10,000 ft. above the sea level, which is reduced one half in the first 150 m. It flows E. through Colorado to near the centre of Kansas, and thence generally S. E. through the Indian territory and Arkansas to its junction with the Mississippi at Napoleon, 275 m. (direct) above New Orleans; length, over 2,000 m. Near its source the river pours with great violence through a deep and narrow fissure in the gneiss rock; after leaving the mountains it traverses a sterile hilly region, sustaining considerable timber. The width of the Arkansas undergoes great variations. From 150 ft. near the mountains, it gradually increases to about a mile as it traverses the sandy desert; and after entering the hilly region it varies from 1,000 to 2,000 ft. Through the prairie region the ordinary depth is about 2 or 3 ft., but there are seasons when the water entirely disappears, being absorbed by the immense beds of sand through which it flows. The range of the river between low and high water is about 45 ft. at Napoleon, 40 at South Bend, 35 at Little Rock, 25 at Fort Smith, and 10 at Fort Gibson, 642 m. from the mouth. It is navigable for steamboats of 3 to 4 ft. draught to a point 40 m. above Little Rock, and during the floods as far as Fort Smith and Fort Gibson. Below Pine Bluff it has been necessary to construct levees to restrain the flood. For a distance of 400 m. from its mouth the Arkansas has many lakes and bayous. Its principal tributary is the Canadian in the Indian territory. The White and Arkansas are connected by a large bayou 6 m. above the junction of the former with the Mississippi, through which the current moves sometimes in one direction and sometimes in another, according to the relative stand of the rivers. The principal points on the Arkansas are Napoleon, Arkansas Post, Pine Bluff, Little Rock,

Van Buren, and Fort Smith in Arkansas, and Fort Gibson in the Indian territory.

ARKANSAS, one of the states of the American Union, situated between lat. 33° and 36° 30' N., and lon. 89° 45' and 94° 40' W., having an extent of 240 m. from N. to S., and varying from 170 to 250 m. from E. to W., the narrowest part being on the S. line and the broadest on the parallel of lat. 36° N.; area, 52,198 sq. m. The state is bounded N. by Missouri, E. by the St. Francis river, separating it from Missouri, and the Mississippi, separating it from Tennessee and Mississippi, S. by Louisiana, S. W. by Texas, and W. by the Indian territory. The state is divided into 64 counties, as follows: Arkansas, Ashley, Benton, Boone, Bradley, Calhoun, Carroll, Chicot, Clarke, Columbia, Conway, Craighead, Crawford, Crittenden, Cross, Dallas, Desha, Drew, Franklin, Fulton, Grant, Greene, Hempstead, Hot Springs, Independence, Izard, Jackson, Jefferson, Johnson, Lafayette, Lawrence, Lincoln, Little River, Madison, Marion, Mississippi, Monroe, Montgomery, Nevada, Newton, Ouachita, Perry, Phillips, Pike, Poinsett, Polk,

Carolina, while the foreigners were chiefly natives of England, Ireland, and Germany. In population Arkansas ranks 26th among the states. The following table will show the increase in population since 1820, the year after Arkansas was organized as a territory :

Census.	White.	Free Col'd.	Slaves.	Total.
1820.....	12,579	77	1,617	14,273
1880.....	25,671	141	4,576	80,388
1840.....	77,174	465	19,985	97,574
1850.....	162,189	608	47,100	209,897
1860.....	324,191	1,4	111,115	435,470
1870.....	362,115	122,169	484,471

In 1870 there were 111,799 persons in the state 10 years old and upward unable to read, and 133,339 unable to write. Of those 21 years old and upward unable to write, 13,610 were white males, 21,770 white females, 23,681 colored males, and 22,689 colored females.— The Ozark mountains, which seldom rise to an elevation beyond 1,500 or 2,000 ft., cross the N. W. corner of the state. They are composed chiefly of limestone, clay slate, sandstone, greenstone, and granite. Extending E. from this range N. of the Arkansas are the Boston mountains, or Black hills. S. of that river is the Masserne or Washita range, which is so barren that the gray sandstone of which it is mainly composed is the prevailing color of the landscape. The eastern portion of the state, bordering on the Mississippi, including a strip ranging from 30 to 100 m. wide, is low and flat, covered by dense forests interspersed with swamps and small lakes or ponds, frequently of stagnant and unhealthy water. This portion is annually overflowed by the floods of the Mississippi, Arkansas, and other rivers. Passing west, the surface gradually rises, and near the centre of the state the country becomes hilly, and the forests are interspersed with rolling prairies. Still further west these hills terminate in the Ozark mountains, and beyond these is an extensive elevated plain continually increasing in height in its course toward the Rocky mountains, in which it finally terminates. The valley of the St. Francis river, in the N. E. part of the state, is a continuous swamp, filled with shallow lakes and bayous, and covered with a heavy growth of cypress, gum, and sycamore, the cypress growing in the water, and the other trees in the marshes or swamps. Rising into the higher land, where the soil is comparatively dry, the surface is covered with a growth of white oak and hickory, with occasional thickly set canebrakes.— Arkansas has no seacoast, but is remarkably favored with navigable streams. The Mississippi river washes its eastern border for a distance of three degrees, though by its tortuous course the actual distance is probably between 300 and 400 m., separating it from Tennessee and Mississippi. The Arkansas river, one of the largest tributaries of the Mississippi, having its source by numerous branches high up in the Rocky mountains, traverses the state by a tortuous route through its centre, the general direction being from N. W. to S. E., for a dis-

State Seal of Arkansas.

Pope, Prairie, Pula-ki, Randolph, St. Francis, Saline, Sarber, Scott, Searcy, Sebastian, Sevier, Sharpe, Union, Van Buren, Washington, White, Woodruff, Yell. There are no large cities. The oldest settlement is Arkansas Post (pop. in 1870, 683), the chief town of Arkansas county, on the river of the same name, about 50 m. above its junction with the Mississippi. It was settled by the French in 1685. Little Rock, Pulaski county, the state capital (pop. 12,380), is also situated on the Arkansas river, about 300 m. above its mouth, in lat. 34° 40' N., lon. 92° 12' W. It was founded in 1820, is built on a commanding bluff, and is a place of considerable traffic. The other chief towns are Fort Smith (pop. 2,227), Helena (2,249), Pine Bluff (2,081), Camden (1,621), Hot Springs (1,276), and Princeton (1,142). The population of Arkansas in 1870 was 484,471, of whom 362,115 were whites, 122,169 colored, 98 Chinese and Japanese, and 89 Indians. Of the total population, 479,445 were native born, and 5,026 foreign born. The native population not born in the state were principally from Tennessee, Alabama, Georgia, Mississippi, and North

tance by the course of the stream of about 500 m., and is navigable far above the limits of the state into the Indian territory. The Red river, a large navigable stream which rises in New Mexico, flows through the S. W. corner of the state. The St. Francis river rises at the foot of Iron mountain in Missouri, forms the boundary between Missouri and Arkansas for a short distance, runs through the N. E. corner of the state, and joins the Mississippi about 13 m. above Helena. Although a large river, its navigation is rendered difficult by numerous rafts or snags. For about 50 m. the river spreads out into a lake from 5 to 20 m. wide, supposed to have been produced by a sinking of the earth caused by the great earthquake of 1811. The St. Francis is 450 m. long, and navigable for 150 m. at favorable seasons of the year. White river rises in the N. W. corner of Arkansas, and, after running N. into Missouri, returns into Arkansas, takes a S. E. zigzag course, and flows into the Mississippi. White river is about 600 m. long, and is navigable for small steamers to Batesville, 260 m. from its mouth, and, when cleared of snags and driftwood, may be ascended at favorable seasons at least 400 m. It has numerous tributaries rising in Missouri, the chief of which are the Black or Big Black, Spring, and Cache rivers. The first flows S. and joins White river 30 or 40 m. below Batesville, and is navigable for steamers during the greater part of the year a distance of 100 m. The Washita or Ouachita rises in the W. part of the state, S. of the Arkansas, runs S. and S. E. parallel with that stream, passing through a beautiful and fertile portion of southern Arkansas, thence S. through a portion of Louisiana, and joins the Red river near its junction with the Mississippi. It is navigable for about 350 m. from its mouth. Its chief tributaries are the Little Missouri, Saline, Bayou Boeuf, &c.—The mineral wealth of Arkansas is as yet comparatively undeveloped. It is known that the state abounds in cannel, anthracite, and bituminous coal, which is found in greatest profusion along the banks of the Arkansas river on either side, from a point a short distance above Little Rock to the western boundary of the state. Iron ore of a good quality has been found in the Ozark mountains. Zinc ore exists more extensively in Arkansas than in any other state of the Union except New Jersey. Galena or lead ore, frequently bearing silver, abounds in various parts of the state. Gold has been discovered in White county, but has never been profitably worked. Manganese is abundant, and, according to De Bow, Arkansas contains more gypsum than all the other states in the Union. Near the hot springs in the Washita valley is an immense bed of superior oil stone, or novaculite, said to be equal to the celebrated Turkish oil stone. Salt of very good quality is produced from the saline springs in the vicinity of Washita and elsewhere.—The climate is temperate, but subject to sudden

changes in consequence of the north winds. The temperature at Little Rock usually ranges from 15° to 99° F., and averages 62·66°, though the mercury has been known to fall as low as 8°. The mean temperature for the winter months is 45·82°; for the summer, 79·66°, the mercury reaching 90° or above for from 40 to 50 days during the summer. Terrible thunderstorms prevail during the spring and summer. The precipitation of rain during the months of July, August, and September, 1871, amounted to 9·23 inches at Mineral Springs, and 3·75 inches at Clarksville.—The total number of deaths in 1870 was 6,119, of which 2,096 were from general diseases; with respect to local diseases, the most numerous deaths were 639 from affections of the nervous system, 1,476 of the respiratory system, and 602 of the digestive system.—The soil of Arkansas varies from the richest and most productive to the most sterile; and the climate and productions are equally varied. The river bottoms, composed of a black alluvium, are wonderfully fertile, producing bountiful crops of cotton, corn, tobacco, sweet potatoes, melons, peaches, grapes, and various other fruits. There are immense tracts of submerged bottoms equally rich, which might be brought under cultivation by a judicious system of drainage. Rising from the valley, the soil becomes less productive, and in many places will not repay cultivation; while large portions of the uplands, particularly in the northern part of the state, produce good crops of wheat and other grain, as well as the best of apples, and are well adapted to grazing. The uplands are largely interspersed with rolling prairies, which are generally well watered, though Grand prairie, 90 m. long and 30 broad, situated between Arkansas and White rivers, is an exception, being almost entirely without water. The low valleys are destitute of good water, the inhabitants resorting to rain water, which is collected and kept in large tanks sunk into the ground, and filtered river water. These valleys are very unhealthy, particularly to the unacclimated. The more elevated portions of the state are salubrious.—The productions of Arkansas are mainly agricultural. The area of the state is 33,406,720 acres, and in 1870 there were 1,714,466 acres of improved and 3,791,873 of wood land. The cash value of farms was \$36,457,476; of farming implements and machinery, \$2,112,020; total amount of wages paid during the year, including value of board, \$3,907,188. There were 83,952 horses, 33,381 mules and asses, 119,607 milch cows, 31,673 working oxen, 179,431 other cattle, 149,592 sheep, 772,662 swine; value of all live stock \$15,795,971. The productions were 683,691 bushels of wheat, 23,422 of rye, 12,208,044 of corn, 486,425 of oats, 46,477 of peas and beans, 399,927 of Irish potatoes, 859,842 of sweet potatoes, 73,021 lbs. of rice, 529,110 of tobacco, 203,275 of wool, 2,531,011 of butter, 12,047 of wax, 261,824 of honey,

221,546 bales of cotton, 6,806 tons of hay, 60,272 gallons of cane and 138,859 of sorghum molasses; value of home manufactures, \$723,979; of slaughtered animals, \$3,466,152; estimated value of all farm products, including betterments and additions to stock, \$36,524,608. The number of manufacturing establishments was 1,364; capital, \$2,137,738. Of these the most important were 272 flour and meal mills, 283 establishments for ginning cotton, 35 for the manufacture of leather, 212 saw mills, and 13 wool-carding establishments.—The state is remarkably well stocked with wild animals, valuable for their meat, hides, and furs, among which are the deer, elk, beaver, otter, rabbit, raccoon, wildcat, catamount, wolf, and bear. Wild turkeys, geese, quails, and various other birds, are also found in great abundance.—The chief exports are cotton, maize, wool, hides, and lumber, which find a market in New Orleans, through which port Arkansas receives her foreign merchandise. A thriving domestic commerce is carried on along the Mississippi, Arkansas, and other navigable streams of the state; and the traffic with the Indians on the western border is of considerable importance.—Among the most striking natural curiosities in the state are the famous hot springs, beneficial to those suffering from the effects of mercury in the system, rheumatism, stiffness of the joints, &c. These springs are situated on a small tributary of the Washita, about 6 m. from that river, and 60 m. S. W. of Little Rock, in Hot Springs county. From 75 to 100 of these springs, varying in temperature from 105° to 160° F., issue from a lofty ridge of sandstone overlooking the town, while a number rise from the bed of Hot Spring creek, which flows at the foot of the ridge, and, by reason of

the springs, is rendered sufficiently warm for bathing in midwinter. In Pike county, on the Little Missouri river, is a natural bridge, and near by is a mountain of very fine alabaster.—Up to Jan. 1, 1870, only 128 miles of railroad had been completed in Arkansas; but many important lines are now in process of construction. The Cairo and Fulton road extends from Cairo, Ill., S. W. across Arkansas past Little Rock to Fulton in Hempstead county, and thence to the Texas line; 301 m. of this road will lie in Arkansas. The Little Rock, Pine Bluff, and New Orleans road extends from the former city to Napoleon on the Mississippi, a distance of 125 m. The Little Rock and Fort Smith road connects these two points, which are distant 156 m. The Memphis and Little Rock extends from a point opposite Memphis, Tenn., on the Mississippi, to Little Rock, and is 130 m. long. The Mississippi, Ouachita, and Red River road extends from Eunice on the Mississippi westerly to Fulton on the Red river, 155 m. The St. James and Little Rock is projected from St. James, Mo., on the Southern Pacific railroad, 104 m. W. of St. Louis, to Little Rock, a distance of 240 m. The Missouri, Kansas, and Texas extends from Junction City, Kansas, on the Kansas Pacific railroad, to Fort Smith, Ark., 325 m. The Memphis and St. Louis extends from Wakefield, opposite Memphis, northerly to Morley, Mo., 142 m., with a branch extending southerly to Helena, 60 m. Under the act of 1868 the number of miles of railroad for which state aid could be granted was limited to 850. The bonds, of the denomination of \$1,000, are payable in 30 years, with 7 per cent. interest payable semi-annually in New York city. The amount of aid awarded to the various companies up to Jan. 1, 1871, is as follows:

NAMES OF ROADS.	Entire length of line.	Miles granted.	Miles of state aid awarded.	Rate per mile.	Amount of state aid awarded.	Amount of stock in road held by state.
Memphis and Little Rock.....	130	115	120	\$10,000	\$1,200,000	\$40,000
Little Rock and Fort Smith.....	156	95	150	10,000	1,500,000	38,125
Little Rock, Pine Bluff, and New Orleans.....	125	45	120	15,000	1,800,000	none.
Missouri and Ohio Railroad.....	160	45	130	15,000	1,950,000	210,500
Cairo and Fulton.....	301	20	300	10,000	3,000,000
Little Rock and Helena.....	98	..	30	15,000	450,000
Total.....	970	323	850		\$9,000,000	\$288,625

The amount of state bonds actually issued to railroad companies to Sept. 30, 1870, was \$2,750,000. Pursuant to an act of the legislature of 1869, 53 m. of levee work have been completed upon the rivers of the state, at a total cost of \$505,917, and 167 m. are in course of construction, comprising levees, railroad beds answering the same purpose, cut-offs, and other works securing land from overflow. By these improvements many acres of valuable land will be reclaimed. In 1870 there were two national banks in Arkansas, with a total capital of \$200,000 and a circulation of \$179,-

500.—The present constitution of Arkansas was adopted Feb. 11, 1868, and ratified by the people March 13, 1868. The equality of all persons before the law is recognized. The ordinance of secession of 1861 and the state debt contracted in waging war against the federal government are declared null and void. The legislature, which assembles biennially on the first Monday of January (odd years), consists of a house of representatives of 82 members chosen for two years, and a senate of 26 members elected for four years. One half of the senators are chosen every two years. Repre-

representatives must be male citizens of the United States not less than 21 years old, must have resided in the state for one year, and be qualified electors and residents of the districts from which they are elected. In addition to these qualifications senators must have attained the age of 25 years. No person holding a federal, state, or county office, with certain exceptions, is eligible as a member of the legislature. A majority of the members elected to each house is sufficient to pass a bill over the governor's veto. Provision is made for taking the census in 1875, and every ten years thereafter; and immediately after every census, state or federal, the legislative districts may be rearranged. The executive power is vested in a governor, lieutenant governor, secretary of state, auditor, treasurer, attorney general, and superintendent of public instruction, who are chosen by the people for a term of four years. The governor must be not less than 25 years of age, a citizen of the United States for five years, an elector and a resident of the state for one year. His salary is \$5,000. No member of congress or person holding a federal or state office is eligible as governor. The executive appoints a commissioner of public works and internal improvements, who is also *ex officio* commissioner of immigration and state lands. The judicial power is vested in a supreme court, 10 circuit courts, and such inferior courts as the legislature may establish. There is a separate chancery court at Little Rock for Pulaski county. The supreme court consists of a chief justice appointed by the governor with the consent of the senate for eight years, and four justices elected by the people for eight years, two being chosen every four years. The judges of the circuit and inferior courts are appointed by the governor with the consent of the senate for six years. Two justices of the peace are elected in each township for two years. General elections are held by ballot biennially on the Tuesday next following the first Monday in November. Every male citizen of the United States, or person who has declared his intention to become a citizen, who has attained the age of 21 years and resided in the state six months next preceding the election, and who is an actual resident of the county in which he offers to vote, is qualified as an elector, except soldiers, sailors, and marines in the United States service stationed in Arkansas, criminals, idiots, the insane, and the following classes: 1, those who during the civil war took the oath of allegiance or gave bonds for loyalty and good behavior to the United States government, and afterward gave aid, comfort, or countenance to those engaged in armed hostility to the federal government; 2, those disqualified as electors or from holding office in the state from which they came; 3, those persons who during the civil war violated the rules of civilized warfare; 4, those who may be disqualified by the 14th amendment to the federal constitution, or by the reconstruction acts of congress. All per-

sons included in the above classes who have openly advocated or have voted for the reconstruction measures of congress, and accept the equality of all men before the law, are deemed qualified electors under the constitution. The general assembly is empowered to remove by a two-thirds vote of each house, approved by the governor, the political disabilities from any person who has in good faith returned to his allegiance to the federal government, except in the case of those who after the adoption of this constitution continued their opposition to the reconstruction measures of congress. A registration of voters is to be made before every general election. All persons before registering or voting must take an oath never to countenance secession, to accept the civil equality of all men, and never to injure or countenance others in injuring any person on account of past or present support of the government of the United States, or the principle of equal rights, or affiliation with any political party. The constitution requires the general assembly to maintain a system of free schools, and enforce the attendance of every child between 5 and 18 years of age for a term equivalent to three years, unless educated by other means. A free school must be kept in each school district for not less than three months during the year. The legislature is also required to establish and maintain a state university, with departments for instruction in teaching, agriculture, and natural sciences, as soon as the public school fund will permit. Liberal provisions are made for the protection of homesteads, and of the separate property of married women; and taxes are limited to 2 per cent. of assessed value.—The funded and unfunded debt of the state, principal and accrued interest, amounted on Jan. 1, 1870, after deducting estimated assets, to \$4,522,297 77, the annual interest on which is about \$300,000. The receipts and expenditures of the principal funds from July 3, 1868, to Sept. 30, 1870, were: General revenue—receipts, \$1,110,483 43, including \$286,703 57 on hand at former date; disbursements, \$927,777 06; school fund—receipts, \$429,449 90, including \$64,875 32 on hand; disbursements, \$370,454 95; permanent school fund—receipts, \$35,591 74; disbursements, \$399 25; military fund—receipts, \$70,302 20; disbursements, \$970 84; sinking fund—receipts, \$142,382 20; disbursements, \$43,779 91; excess fund—receipts, \$108,932; disbursements, \$2,368 23. According to the census of 1870, the assessed value of real estate was \$53,102,304; personal property, \$31,426,539; true value of real and personal estate, \$156,394,691; total taxation not national, \$2,866,890. At present the state tax amounts to 9½ mills on the dollar, of which 5 mills are for general purposes, 2 mills for school purposes, and 2½ mills for the payment of interest on the public debt.—The present system of free public schools was established in 1868. The number of children of school age in 1870 was 180,274; attending school, 107,908; teach-

ers employed, 2,302; number of teachers' institutes, 41; teachers attending institutes, 944; whole amount paid teachers in 1870, \$405,748; number of school houses built in 1869 and 1870, 657; persons subject to per capita tax of \$1 in 1869, 79,544; per capita tax collected in 1869, \$61,465; number of schools taught in 1870, 2,537. The second apportionment of the school fund, based on the school tax for 1869, was made in 1870, and amounted to \$187,427 08. The common school fund on Oct. 1, 1870, amounted to \$58,954 95, and the permanent school fund to \$35,192 49. In 1868 the legislature accepted the grant of land, amounting to about 150,000 acres, made by congress in 1862 toward the support of a college of agriculture and the mechanic arts, and provided for the creation of the Arkansas industrial university, not yet established.—Among the state institutions, all at Little Rock, are the institute for the blind, having 38 pupils in 1868; the deaf mute institute, with 43 pupils in 1870; and the penitentiary, with 199 prisoners in 1870. There are published in the state 4 daily, 2 tri-weekly, and 41 weekly papers, and 4 monthly periodicals. The average circulation of each issue is 650, and the aggregate annual circulation 2,438,716.—Arkansas was originally a portion of the territory of Louisiana, purchased from the French in 1803. It remained a part of Louisiana territory till 1812, when the present state of Louisiana was admitted to the Union, and the remaining portion was organized as Missouri territory, which name it held till 1819, when Missouri formed a state constitution and Arkansas was erected into a territory bearing its present name. It remained under a territorial government till June, 1836, when a constitution was formed at Little Rock, and Arkansas became a state. In January, 1861, the people decided by a vote of 27,412 to 15,826 in favor of a convention to consider the question of secession. That body assembled in March, and deferred the decision to a popular election to be held in August. Meanwhile the state authorities seized the arsenals at Little Rock (Feb. 8) and Napoleon (April 24), and upon Fort Smith on the western border (April 23). The convention reassembled May 6, in consequence of President Lincoln's call for troops, and passed the ordinance of secession by a vote of 69 to 1, withdrawing the submission of the question to the people. The battle of Pea Ridge, or Elk Horn, in N. W. Arkansas, was fought March 6 and 7, 1862, between the confederates under Van Dorn and the Union forces under Curtis, and resulted in a victory of the latter, who then advanced to the Mississippi and occupied Helena. On Dec. 7, 1862, the confederate general Hindman, attempting to prevent the junction of Gens. Blunt and Heron, was defeated by Blunt at Prairie Grove near Fayetteville, with a loss of about 1,200. Arkansas Post, on the Arkansas river, was captured by Gen. McClelland and Admiral Porter, Jan. 11, 1863. The confederates under

Holmes attempted to retake Helena July 4, but were defeated by Gen. Prentiss. Little Rock was taken by an expedition commanded by Gen. Steele, Sept. 10, without serious resistance, while the W. and S. parts of the state were occupied by Blunt and Stephenson, Holmes being driven into Texas; but the confederates recovered possession of most of the southern counties after the reverse of Gen. Banks in Louisiana (April, 1864). On Oct. 30, 1863, a meeting of loyal citizens representing about 20 counties was held at Fort Smith to institute measures for reorganizing the state government. A convention assembled at Little Rock Jan. 8, 1864, when representatives from 42 counties were present, and framed a loyal constitution. At an election held on March 14, 15, and 16, 12,177 votes were cast for the constitution and 226 against it. State and county officers, representatives in congress, and members of the legislature from 40 counties were elected; and in April a state government was organized. During 1865 much suffering and destitution prevailed among the people, and in May the federal government issued 75,097 rations to refugees and 46,845 to freedmen. Under the reconstruction act of March 2, 1867, declaring that "no legal state governments or adequate protection for life or property now exists" in the states lately in rebellion, Arkansas and Mississippi were constituted the fourth military district. A registration of voters was made under instructions from Gen. Ord, and delegates were elected in November to a constitutional convention which assembled at Little Rock Jan. 7, 1868. The new constitution was ratified by a small majority of the people in March. On June 22 congress passed over the president's veto a resolution admitting Arkansas to representation, and the administration was thereupon transferred to the civil authorities. On Nov. 9, 1868, Gov. Clayton declared 10 counties in a state of insurrection. On March 22, 1869, martial law ceased throughout the state. The 14th amendment to the federal constitution was ratified in April, 1868, and the 15th in March, 1869.

ARKANSAS, a S. E. county of Arkansas, bounded E. by White river and intersected by the Arkansas; area, about 1,200 sq. m.; pop. in 1870, 8,268, of whom 4,212 were colored. The surface is level, and about one third of it is occupied by the Grand prairie, the largest in the state, and very fertile. The county in 1870 produced 217,450 bushels of Indian corn, 17,327 of Irish and 28,598 of sweet potatoes, and 12,315 bales of cotton. Capital, Arkansas Post.

ARKWRIGHT, Sir Richard, an English inventor, born at Preston, Lancashire, Dec. 23, 1792, died at Cromford, Derbyshire, Aug. 3, 1792. He was the youngest child of a family of 13, and his parents were too poor to give him any education. He earned his living as a barber, shaving in a cellar for a penny, till he was 28, when he became a dealer in hair, and invented

a dye by the sale of which he accumulated a little property. His first experiments in mechanics were attempts to solve the problem of perpetual motion; but he soon directed his attention to improvements in the cotton manufacture. At that time English cottons were made with only the weft of cotton, the warp being of linen, and it was considered impossible to spin cotton fine and strong enough for the warp. Moreover, the supply of weft was short of the demand, though Hargreaves of Lancashire had shortly before invented his jenny, and had several machines at work in Nottingham. In 1768 Arkwright produced the model of his famous cotton-spinning frame, by which the thread could be spun of any required fineness and strength and with immense velocity. Fearing the same hostility that had driven Hargreaves out of Lancashire, he proceeded at once to Nottingham. There he met with Messrs. Wright, bankers, who engaged to furnish the capital necessary to perfect the invention, but soon became frightened and retired. Arkwright then applied to Messrs. Need and Strutt, and the latter (the celebrated inventor of the stocking frame) saw at once the value of the invention, and the firm took an interest in it. Arkwright was profoundly ignorant of mechanics, but a few suggestions of Mr. Strutt about the wheel work overcame the last difficulty, and a machine driven by a horse was soon in operation. In 1771 another mill, driven by water power, was established at Cromford, in Derbyshire. The first patent was granted in 1769, and unsuccessfully contested in 1772. In 1775 Arkwright obtained a new patent for improvements, but it seems he had included in it things discovered before, and six years later it was declared void by the courts; but in 1785 he obtained a decision in his favor, and was reinstated in the monopoly. The object of Arkwright's invention was to spin cotton fine, with a hard twist, and fit for warp. This was done by the use of drawing-rollers, by sets of two, the second set moving faster than the first, and by a fast-revolving spindle giving a twist to the cotton as it came out from between the second pair. The introduction of this machine, which was far superior to that of Hargreaves, caused the latter to die of grief. Arkwright encountered the bitterest hostility, not so much from the working class as from the manufacturers, who at one time even refused to buy his yarns, and tried to ruin him by mischievous legislation in parliament. His energy and perseverance, however, triumphed over all obstacles. In the management of his mill he showed a remarkable capacity for organization, and his labors were rewarded with a fortune of £500,000. He acquired the rudiments of learning after he was 50 years old, was knighted in 1786 on occasion of presenting an address to the king, and in 1787 served as high sheriff of Derbyshire. His invention enables one man to do as much work as 130 could do before, and it is calculated that

40,000,000 hands would scarcely be sufficient to accomplish the spinning now done by machinery in England alone.

ARLES (Celtic *Ar-lait*, near the waters; Lat. *Arelate*), a town of France, in Provence, department of Bouches-du-Rhône, on the left bank of the lower Rhône, at the point where the river divides and forms the island of Camargue, 46 m. N. W. of Marseilles; pop. in 1866, 26,367. It is an ill-built and somewhat unhealthy place, though situated amid beautiful environs. Its ancient amphitheatre, although not as well preserved as that of Nîmes, is superior in size and magnificence. An obelisk, consisting of a single block of granite about 50 feet high, is yet standing on one of the public thoroughfares, while the ruins of an aqueduct, of two temples, of a triumphal arch, an extensive cemetery, and numerous fragments of granite and marble columns, are to be seen in different parts of the city. The statue known as the Venus of Arles, a rival to the Venus de' Medici, now in the national museum of Paris, was discovered here in 1651. The Roland tower and the Byzantine church of St. Trophimus deserve mention, as also the town hall, designed by Mansard. Arles contains a school of navigation, a college, a collection of natural history, a museum of antiquities, a public library, and a theatre. Silk, soap, and glass bottles are manufactured, and the sausages of Arles are held in high esteem.—The ancient Arelate was an important town at the time of Caesar's invasion, became a prosperous Roman colony, was for a time the residence of Constantine, became the capital of the Gothic king Euric, was plundered by the Saracens in 730, and 150 years later became the capital of Cisjurane Burgundy, and in 930 of both Cisjurane and Transjurane Burgundy, united as the kingdom of Arelate or Arles. (See *BURGUNDY*.) In 1251 it came into the possession of Charles of Anjou, count of Provence. It was united to the crown of France under Louis XI. Several important ecclesiastical synods were held here in the 4th and 5th centuries.

ARLINCOURT, Victor, viscount d', a French poet and novelist, born in 1789, died Jan. 22, 1856. His father, a farmer of the public revenue, died by the guillotine in the revolution. Victor commended himself to Napoleon's notice by publishing in 1810 an allegorical poem in his honor, entitled *Une matinée de Charlemagne*, for which he was rewarded with two court offices. He afterward undertook an epic, the hero of which was still Charlemagne, or rather Napoleon, but it was unfinished on the fall of the empire. D'Arlecourt easily transferred his political allegiance to the Bourbons, but did not meet with favor from Louis XVIII. The publication of his *Carolède* was soon followed by several novels, *Le Solitaire*, *L'Étranger*, *Le Renégat*, *Ipsihôé*, and *Ismaïlie*, the last being in rhyme. These eccentric works acquired an equivocal sort of celebrity, *Le Solitaire*, of which Charles the Bold was the hero,

having been translated into several languages and widely circulated. His tragedy, *Le Siège de Paris*, played at the Théâtre-Français, was received with such bursts of laughter that the actors did not attempt a second performance. In the latter part of his life he fell into obscurity.

ARLON (anc. *Orolannum*), a town of Belgium, capital of the province and 16 m. W. N. W. of the city of Luxemburg; pop. in 1867, 5,779. It is situated in the midst of forests on a ridge of the Ardennes, and is rapidly increasing in prosperity owing to its ironware, leather, and other manufactures. It was known to the Romans. At the end of the 18th century it was the scene of various engagements between the Austrian and French armies.

ARMADA, Spanish, the great naval armament sent by King Philip II. of Spain, in 1588, for the conquest of England. The fullest account of this armament is given in a book published about the time it set sail by order of Philip, under the title *La felicissima Armada que el rey Don Felipe nuestro Señor mandó juntar en el puerto de Lisboa 1588, hecha por Pedro de Paz Salas*. A copy of this work was procured for Lord Burleigh, so that the English government was beforehand acquainted with every detail of the expedition. (This copy, containing notes up to March, 1588, is now in the British museum.) The fleet is therein stated to have consisted of 65 galleons and large ships, 25 *urcas* of 300 to 700 tons, 19 tenders of 70 to 100 tons, 13 small frigates, 4 galleasses, and 4 galleys; in all, 130 vessels, with a total tonnage of 75,868 tons. They were armed with 2,431 guns, of which 1,497 were of bronze, mostly full cannon (48 pdrs.), culverines (long 30 and 20 pdrs.), &c.; the ammunition consisted of 123,790 round shot and 5,175 cwt. of powder, giving about 50 rounds per gun, at an average charge of 4½ lbs. The ships were manned with 8,456 sailors, and carried 19,295 soldiers and 180 priests and monks. Mules, carts, &c., were on board to move the field artillery when landed. The whole was provisioned, according to the above authority, for six months. This fleet, unequalled in its time, was to proceed to the Flemish coast, where another army of 30,000 foot and 4,000 horse, under the duke of Parma, was to embark, under its protection, in flat-bottomed vessels constructed for the purpose, and manned by sailors brought from the Baltic. The whole were then to proceed to England. In that country Queen Elizabeth had, by vigorous exertions, increased her fleet of originally 30 ships to about 180 vessels of various sizes, but generally inferior in that respect to those of the Spaniards. They included a large number of privateers, armed merchantmen, and vessels furnished by the nobility, and were manned by 17,500 sailors. They were wretchedly provisioned, and so ill supplied with ammunition that they could hardly have made a serious fight but for the powder which they captured from the enemy. The English military force was divided into

two armies: one, of 18,500 men, under the earl of Leicester, for immediately opposing the enemy; the other, of 45,000, for the defence of the queen's person. According to a MS. in the British museum, entitled "Details of the English Force assembled to Oppose the Spanish Armada" (MS. Reg. 18th, c. xxi.), 2,000 infantry were also expected from the Low Countries. The armada was to leave Lisbon in the beginning of May, but, owing to the death of the admiral Santa Cruz and his vice admiral, the departure was delayed. The duke of Medina Sidonia, a man totally unacquainted with naval matters, was now made captain general of the fleet; his vice admiral, Martinez de Ricalde, however, was an expert seaman. Having left Lisbon for Corunna for stores, May 29, 1588, the fleet was dispersed by a violent storm, and, though all the ships joined at Corunna with the exception of four, they were considerably shattered, and had to be repaired. Reports having reached England that the armament was completely disabled, the government ordered its own ships to be laid up; but Lord Howard, the admiral, opposed this order, set sail for Corunna, learned the truth, and on his return continued warlike preparations. Soon after, being informed that the armada had hove in sight, he weighed anchor, and as it passed Plymouth, July 31, stood out in its rear and opened a destructive fire. Having the windward position, and being greatly superior in speed, he was able to inflict serious damage without loss to himself. All the way along the channel the English followed the armada with the same tactics, taking skilful advantage of the changing winds, harassing the Spaniards, capturing two or three of their best vessels, and yet keeping all the while virtually out of reach. The Spaniards proceeded toward the coast of Flanders, keeping as close together as possible. In the various minor engagements which took place, the English always won the victory over the clumsy and undermanned Spanish galleons, crowded with soldiers. The Spanish artillery, too, was very badly served, and almost always planted too high. Off Calais the armada cast anchor, waiting for the duke of Parma's fleet to come out of the Flemish harbors; but Parma had nothing but unarmed barges, and could not come out until the armada had beaten off the Anglo-Dutch blockading squadron. Driving the Spaniards out of Calais roads by means of fire ships, Aug. 8, Howard and Drake now forced them toward the Flemish coast, with the purpose of getting them into the North sea and cutting off their communications with Dunkirk. The battle began at daybreak off Gravelines, and lasted till dark. The Spaniards were completely defeated. Several of their largest ships were lost, and 4,000 men were killed, and probably at least as many more wounded. It was impossible either to return to Calais or to reach the duke of Parma. The provisions were nearly exhausted, and the English fleet, apparently little injured, still

hovered on their weather beam. It was imperative that they should return to Spain for fresh stores. The passage through the channel being closed by the English fleet, the Spaniards, now counting 120 vessels, undertook to round Scotland and Ireland. But in the neighborhood of the Orkneys they were dispersed by a storm. Some of them foundered. About 30 were afterward wrecked on the W. coast of Ireland. Those of the crews who escaped to shore were killed generally, and it was calculated that about 14,000 thus perished. The remnant which reached Spain in September and October, with *Sidonía* and *Recalde*, numbered only 54 vessels and 9,000 or 10,000 starving men.

ARMADILLO (*Dasypus*, Linn.), a genus of the class *mammalia* and order *edentata*, forming a small family, intermediate between the sloths and ant-eaters, and having an affinity to the families *chlamyphorus* and *orycteropus*. They are distinguished by the possession of molar teeth only. The armadillos have a singular coat armor covering their whole body and head. It consists of three bony bucklers, composed of small polygonal plates set in juxtaposition to one another, but neither connected by joints nor separately movable. The bucklers which cover the rump and shoulders of the animal, each forming as it were a single solid piece, are capable of little pliancy or motion save what is allowed during the life of the animal by the partial elasticity of the thin shell

Armadillo (*Dasypus sexcinctus* or *D. encoubert*).

or crust lubricated by the animal oils which penetrate it. These bucklers, however, are connected by a number of transverse movable bands, composed of similar plates with the principal bucklers, which are themselves connected by the soft and pliant inner skin of the animal, and thus admit of the most rapid motions, being situated immediately above the loins. The buckler or helmet which defends the head has no connection of any sort with the armor of the shoulders, so that the neck is left perfectly free, while it is at the same time completely protected by the projection of the skull-piece. The legs of the armadillos are extremely short and stout, covered with scaly plates, furnished with powerful claws for bur-

rowing in the ground, and guarded as far as the knees by the defending bucklers; these descend so low as to make a complete defence to the belly of the animal, which is covered only with a rough skin, from which originate a few long coarse hairs, and a partial one to the thighs and knees. Except in one species, the armadillos are devoid of hair, save that above mentioned, and a few straggling bristles, which proceed from the inner skin, between the jointed plates of the lumbar region. The tails of all the species but one are armed with annular bands similar to those connecting the bucklers, and in all are adapted to a notch cut out of the posterior buckler in order to receive them. The teeth of the armadillos are of simple cylindrical form, varying from 7 or 8 to 17 or 18 in number, on each side of each jaw, and when the mouth is closed shut one into another. The different species have 4 or 5 toes on their fore feet, and invariably 5 on their hind feet. Their eyes are small, their ears erect and pointed, and they have elongated snouts. They are mostly nocturnal in their habits, though a few of the species go abroad by day; perfectly inoffensive; are never known to bite, or attempt any defence; but when pursued immediately commence burrowing, which they do with such power and rapidity that they easily evade their pursuers. The ordinary food of armadillos consists of fallen fruits, roots, worms, ants, and carrion. Their grinding teeth enable them to feed only on soft substances, and therefore they can devour flesh only when putrid. Abundance of this food they find at all seasons on the pampas of South America, where cattle are slaughtered for the sake of their hides alone. On this food the armadillos become immensely fat, when they are esteemed a great delicacy and are served up roasted whole in their shells.—The armadillos are arranged by Cuvier in five small groups, according to the arrangement of their teeth, toes, and other structural differences: 1. The caehiemes, with 4 anterior toes, 7 teeth on a side, above and below, a pointed muzzle, and a long, annulated tail. 2. The aparas, with toes and tail as the last species, but with 9 or 10 teeth on each side, above and below. This animal has also the power of rolling itself into a ball like a hedgehog. 3. The encouberts, with 5 anterior toes and 9 or 10 teeth, throughout. In addition, however, they have 2 teeth on the intermaxillary bones of the upper jaw resembling incisors, in which they differ not only from all armadillos, but from all the order *edentata*. 4. The kabassous, which have 5 toes both before and behind, but the claws obliquely arranged, so as to give them unusual power in burrowing and clinging to the soil when seized. They have 9 or 10 teeth, throughout; and their tails are undefended by armor, as in the other species. 5. The priodontes, or last subdivision of the armadillos, in addition to the unequal toes and enormous claws of the kabassous, have

from 22 to 24 small teeth, throughout, on each side of both jaws. Of the cachicames, or first division, there are three species, of which the commonest is the *dasyppus peba*, or black tatu of Paraguay. It is about 16 inches long, and was originally known under the appellations of the 7, 8, and 9-banded armadillo, three species being made out of one. The other species of this group are the mule tatu, so called from the length of its ears, and the tatu verdadero, hardly distinguishable from the last, except by the breadth of the movable bands and the size of the group buckler. Of the aparas, there is but one species, the mataco, which has in general but 3 bands and a short, blunt tail, covered by a single horny crust. The encouberts have three species: the poyon, or yellow-footed armadillo, which has usually but 7 or 8 movable bands, and is easily known by its triangular snout, flat body, and short legs; the hairy armadillo, remarkable for its more copious growth of bristles from between the movable bands, and for its practice of burrowing into the bodies of dead horses, and remaining within them until all the flesh is consumed, and nothing left but the skeleton and hide; and lastly the pichiy, which is the smallest of all the armadillos. The kabassous have but one species, the tatouay, or wounded armadillo, so called by the Indians from an idea that the scaly covering of its tail, which is naked and looks raw, has been torn off by violence. The last subdivision of armadillos, the priodontes, has likewise but one species, the *dasyppus gigas*, or great armadillo of Cuvier. It is remarkable for its size, being 3 feet 3 inches long: for its movable bands, 12 or 13 in number, composed of rectangular plates; for the thickness of its tail at the base; and for the spiral lines of the scales by which it is defended. All the armadillos are inhabitants of Central and South America, being found dispersed from Mexico, over the pampas of Buenos Ayres, and south as far as Paraguay. The armadillo runs with remarkable speed, easily outstripping a man. Although the females in no species have more than 4 mammae, and in some but 2, they invariably produce 6, 8, or 10 young at a birth, bearing but once in a season.

ARMAGEDDON (Heb. *har*, hill, and *Megiddo*), the name probably given to the whole table land of Esdracel in Galilee and Samaria, from the town of Megiddo, which stood near the centre of it, upon the site, according to Dr. Robinson, of the modern Lejjun (the Roman Legio). Armageddon was the great battlefield of Palestine. On this elevated plain were fought the battles of the Kishon, Jezreel, Gilboa, and Megiddo. The fame of this field of many battles explains the passage (Rev. xvi. 14-16) in which the seer of the Apocalyptic vision describes God as summoning his foes to "a place called in the Hebrew tongue Armageddon," to the battle of the "great day of God Almighty."

ARMAGH. 1. A county of northern Ireland, in the province of Ulster, between Lough Neagh

on the north and the county of Louth on the south; area, 512 sq. m.; pop. in 1871, 171,355. In the S. W. part are several groups of considerable mountains; the rest of the surface is level or undulating, and the soil is generally fertile. The principal rivers are the Blackwater and the Bann. The northern and central portions of the county are divided into small farms; grain, vegetables, and flax are their products. Linen weaving is the chief manufacturing industry. The principal towns are Armagh and Newry; part of the latter lies also in the county of Down. Portadown and Lurgan are noted for their linen manufactures.

II. A city, capital of the preceding county, situated on the Callan, an affluent of the Blackwater, 36 m. by railway W. S. W. of Belfast; pop. in 1871, 8,952. It is well built round a hill, from the centre of which rises the famous old cathedral, recently repaired and occupying the site of the original building erected by St. Patrick. The town is supplied with water from an adjoining reservoir and is lighted with gas. The Anglican and Roman Catholic archbishops of Armagh both bear the title of primate of all Ireland. The trade chiefly consists in grain, flax yarn, and linen. It has several branch banks, and lively weekly corn and general markets, and the prosperity of the town is rapidly increasing. Between the 5th and 9th centuries Armagh was a renowned ecclesiastical and intellectual centre, and subsequently it was often devastated by the Danes. After the English invasion it was almost uninterruptedly under Irish rulers up to the reformation, after which period it became the scene of many conflicts between the English and Irish forces till the beginning of the 17th century. The military headquarters, formerly in Armagh, have been removed to Belfast.

ARMAGNAC, an ancient territory of France, in the province of Gaseony, now forming the department of Gers, and a part of Lot-et-Garonne, Tarn-et-Garonne, and Haute-Garonne. It was successively included in Aquitaine, in the duchy of Gascony, and in the county of Fézenac, and was erected into a separate county in 960. Its rulers during the 14th and 15th centuries became very powerful. Louis XI. united it to the crown in 1481. But it was restored by Charles VIII., reunited to the crown on the death of the last count in 1497, and, after new changes, descended to Henry of Navarre, who incorporated it with the kingdom of France on his accession in 1589. Louis XIV. gave the title to Henry of Lorraine in 1645, and it was borne by his descendants until the revolution. Of the ancient counts of Armagnac, the most distinguished were the following: **I. Bernard VII.**, killed June 12, 1418. He distinguished himself in the war with the English in Guienne. When the murder of Louis, duke of Orleans, brother of Charles VI., by the emissaries of John the Fearless, duke of Burgundy, left the Orleanists without a chief (1407), he married

his daughter to young Charles of Orleans, became the leader of the faction which henceforth assumed the name of Armagnac, and was appointed by the queen constable of France. He succeeded in seizing on Paris, which he governed with an iron rule. At last the Parisians became tired of his tyranny, and by treason delivered the city into the hands of L'Isle-Adam, one of the Burgundian chiefs. Bernard hid himself, but was betrayed by a mason in whom he had confided, and was imprisoned. A few days later the jails were mobbed by the populace, when all the Armagnacs were murdered, Bernard among the rest.

II. Jean V., grandson of the preceding, born about 1420, assassinated in 1473. He made himself notorious by his uncontrollable passions, and publicly married his own sister, Jeanne Isabelle, who had been engaged to King Henry VI. of England. This crime was made a pretext by Charles VII. for depriving him of his possessions, which were afterward restored to him by Louis XI. Notwithstanding this, Jean entered the league of the public weal against Louis, and was driven into Aragon; but by the aid of Louis's brother, the duke of Guienne, he recovered his estates, and withstood a siege in the castle of Lectoure. The royalists obtained an entrance by stratagem, put the count to death, and forced his wife to drink of a poison which killed both herself and her unborn child.

ARMAND, Charles. See **ROUARIE**, Marquis de la.

ARMANSPERG, Joseph Louis, count, a Bavarian statesman, regent of Greece, born in Lower Bavaria, Feb. 28, 1787, died April 3, 1853. In the war of 1813-'14 he was commissioner of Bavaria in the allied army, and belonged to the board which governed the conquered regions on the Rhine. He participated in the congress of Vienna in 1815, was one of the plenipotentiaries with the allied army during the occupation of France, and administered a large district of that country. In 1825 he was chosen president of the chamber of deputies, and became leader of the moderate opposition. King Louis I. made him secretary of the treasury and of foreign affairs. He was one of the founders of the German Zollverein. By his opposition to the ultramontanes he forfeited the confidence of the king, and retired into private life, but in 1832 was recalled to take the regency of Greece during the minority of King Otho. He entered Greece in February, 1833, and ruled until 1837 with almost limitless power. His administration was in many respects beneficial, but he finally became unpopular with the nation, the sovereign, and all the foreign diplomatists except the English minister, and was dismissed.

ARMATOLES, Christian captains commanding bands of klephts or brigands, who, after the establishment of the Ottoman empire in Europe, succeeded in maintaining themselves independent in the possession of inaccessible mountain defiles. These warlike chiefs, con-

stantly striving for the independence of Greece, became more and more formidable, especially in Epirus and other parts of northern Greece; and about the beginning of the 17th century the pashas were obliged to treat with them, and admit their right to govern their mountain country. They took a leading part in the Greek revolution; and among the armatolic chieftains most distinguished in this war were Eustrates, Gogo, Makry, Saphacac and Karaïskakis (both of whom perished under the walls of Athens in 1827), Kaltzodemos (killed before Missolonghi), Odysseus, Panuryas, and Marco Bozzaris, the commander of the Suliotcs.

ARMENGAUD, Jean Germain Désiré, a French art historian, born at Castres, department of Tarn, in 1797, died at Passy, near Paris, in March, 1869. He is the author of *Histoire des peintres de toutes les écoles depuis la renaissance jusqu'à nos jours* (1849, completed by Charles Blanc), *Les galeries publiques de l'Europe* (1856), *Les chefs d'œuvres de l'art chrétien* (1858), *Les trésors de l'art* (1859), *Le Parthénon de l'histoire* (1863-'4), and other illustrated works.

ARMENTIÈRES, a town of France, in the department of Le Nord, situated on the Lys, opposite the Belgian frontier, 10 m. N. E. of Lille; pop. in 1866, 15,579. It has a college, an insane asylum, and important manufactures of linen and cotton goods. Formerly the town was fortified, but after its conquest by Louis XIV. the works were razed.

ARMENIA, an inland region of western Asia, mostly within the present limits of Asiatic Turkey, but extending into the adjacent dominions of Russia and Persia. Its boundaries have varied greatly at different periods, and are not now authoritatively fixed, estimates of its area varying from 50,000 up to 150,000 sq. m. In its largest sense, it formerly reached toward or to the Caucasus mountains on the N., nearly or quite to the Caspian sea on the E., included (according to some) the modern lake of Urumiah on the S. E., and embraced a part of Cappadocia on the S. W. and W.; thus extending from about lon. 36° to 49° E. and from about lat. 37° to 42° N. Armenia Minor or Lesser Armenia lay W. of the Euphrates, and was the eastern part of Asia Minor; Armenia Major or Greater Armenia, usually called simply Armenia, sometimes Armenia Proper, lies entirely E. of the Euphrates. In its most flourishing period Armenia was divided into 15 provinces and 187 cantons or subdivisions, the central province being Ararad or Ararat. Armenia Major is an elevated and mountainous region, watered with abundant rains, and covered for some months in the year with deep snows. Its climate is severe for its latitude, which is that of New Jersey and Delaware, but is generally healthy. Its winter lasts from October to May; its summer is short and warm. It has five principal rivers; the Euphrates and Tigris, which unite and flow into the Persian gulf; the Kur (an-

ciently Cyrus) and Aras (Araxes), which unite and fall into the Caspian sea; and the Tchouk (anciently Acampsis), which falls into the Black sea. A high table land, 4,000 to 8,000 ft. above the sea, constitutes a considerable part of the country, and is supposed to have been once a large inland sea, from which the Taurus, Antitaurus, and other mountains were upheaved by volcanic action. Its highest mountain is the Great Ararat, which rises more than 3 m. above the level of the sea, and is covered with perpetual ice and snow. An eruption of Ararat and disastrous earthquakes occurred in 1840. Traces of volcanic action abound through a large part of this whole region. Among its rocks are trap, porphyry, basalt, granite, syenite, limestone, sandstone, &c. It has mines of gold, silver, lead, iron, copper, and rock salt. Its largest lake, Van, is salt, nearly 5,500 ft. above the sea, with an area of about 1,400 sq. m. The lake of Urumiah is also salt, but is not generally included in Armenia. The lake of Sevan in Russian Armenia is sometimes called "sweet sea," to distinguish it from the salt lakes. The agricultural resources of Armenia are good, but, in consequence of misgovernment, much of the land is unimproved. There are rich pastures; some parts yield abundantly grain, tobacco, manna, hemp, cotton, melons, cucumbers, grapes, figs, pomegranates, apples, peaches, mulberries, and walnuts. Among its forest trees are chestnut, beech, walnut, ash, maple, pine, fir, and oak. Horses, cows, oxen, buffaloes, sheep, and goats are common domestic animals. Erzerum, generally considered the chief city of Turkish Armenia, is the abode of a high pasha, who bears the title of seraskier. Van, Bayazid, Kars, Bitlis, and Mush, to which some add Diarbekir and Batum, are other important places in Turkish Armenia. Erivan, Nakhtchevan, Shusha, and Akhaltzikh are leading cities of Russian Armenia, which also contains Etelmiadzin, the abode of the catholicos or head of the Armenian church. Urumiah, Khoi, and even Tabriz, in Persia, have been reckoned as cities of Armenia.—The Armenians proper, who however form but a small portion of the inhabitants of Armenia, call themselves *Haiks*, from a traditional ancestor Haig or Haiens, whom they represent as the son of Togarmah, who was a great-grandson of Noah through the line of Japheth and Gomer (Gen. x.). Haig, they say, was one of the prefects or directors in building the tower of Babel, but, refusing to pay divine homage to the image of Belus, who reigned in Babylonia, went northward with his family and others into the region of Ararat. Belus or Bel pursued them, and was slain in battle by Haig, who then went on to found cities, introduce wise laws and regulations, and promote the prosperity of his people, till his death, at the age of nearly 400 years. His eldest son, Armenag, succeeded him as king, and was himself succeeded by his son Aramais, who gave name to

Armavir, a large and beautiful city, built of hewn stone, and situated probably at a place called Kasagh, near the Araxes. Armavir was the capital of the kingdom for about 1,800 years, while the Haig dynasty, including 59 kings, were on the throne. Aram, the seventh of this dynasty, and contemporary with the patriarchs Isaac and Jacob, is said to have defeated the Babylonian and Median invaders, conquered a large part of Asia Minor, and built the old city of Mazaca, afterward called Caesarea and Kaisariyeh, in Cappadocia; and according to some traditions it was he (according to others Armenag) who left his name to Armenia. His son Arah, renowned for his beauty, was sought in marriage by Semiramis, and lost his life in the disastrous battle which followed his refusal. Semiramis grieved much over his death, placed on his throne his young son Gartos, also called Arah, and founded a magnificent city, long known among the Armenians as Shamiramagerd (city of Semiramis), now Van, which she made her royal summer residence. The Armenians were now for some time tributary to the Assyrians; but their ruler Parsuis is said to have joined the Median prince Arbaces and the Babylonian Belesis in destroying the empire of Sardanapalus, and to have afterward, as king of Armenia, hospitably received Sennacherib's sons Adrammelech and Sharezer, whose posterity subsequently established the kingdom of Vashburagan. Haikak II., king of Armenia 607-569 B. C., joined Nebuchadnezzar in his expedition against the Jews, and brought into Armenia a Jewish noble named Shambat with his family. From this Shambat descended the Armenian royal family of the Bagratides or Bagradites, some of whom, under the name Bagration, still hold high offices in Russia. The Armenians celebrate Tigranes I. or Dikran as their most powerful and excellent king, who put the Greeks under tribute; aided Cyrus the Persian in conquering the Medes, Lydians, and Babylonians; built Tigranocerta; reigned 45 years, and died five years after Cyrus. His son and successor Vahagn gained by his great courage and strength the title of Hercules the second, and was worshipped as a god. Van, king 371-351 B. C., enlarged and embellished the city of Semiramis and called it by his own name, Alexander the Great having defeated Vahag and brought the Haig dynasty to an end, the Armenians were for 164 years (323-159) ruled by governors really or nominally subject to the Macedonians or Syrian Greeks. The Romans make Artaces or Artaxias, one of these governors, and an Armenian, the founder of an independent kingdom and of the dynasty of the Arsacidae, as well as of the city and capital Artaxata, on the Araxes, about 189 B. C. The Armenians make the founder of this dynasty to be Vagharshag or Valarsaces, brother of the Parthian king Arshag or Arsaces the Great, who gave Nisibis to Valarsaces for his capital about 149. According to the Romans, also,

Zadriates, another prefect or governor, became king of Armenia Minor about 189; but his kingdom lasted only a short time. Great obscurity rests on the history of Armenia under the Arsacidae. Tigranes II., sometimes called Tigranes the Great, and also Tigranes I., was, according to the Armenians, a great conqueror, and brother-in-law of the Georgian chief Mithridates, whom he appointed king of Pontus. This Tigranes is said to have made Nisibis his capital, rebuilt the old Tigranocerta, and founded another city of the same name on the Nymphius, a branch of the Tigris. His son and successor Ardavast was treacherously seized by Mark Antony, carried in chains to Egypt, and put to death in 34 B. C. Alexander, son of Antony and Cleopatra, ruled in Armenia a little while; but, after various changes, we find Abgar or Abgarus, grandson of Tigranes the Great, on the throne of Armenia at Edessa. The Armenians universally believe that this Abgar wrote the famous letter to Jesus which is quoted as genuine by Eusebius and others. In his reign all parts of Armenia became tributary to the Romans. About A. D. 78 Erovant transferred the capital to Armavir, and then built a new capital, Erovantashad, a little W. of Armavir. The Armenians speak of another Artaces, who ruled A. D. 88-129, built bridges, roads, and ships, encouraged literature, science, commerce, and every branch of industry, and died universally lamented; but Armenia afterward suffered much from struggles with and between the Romans and Parthians, and from persecutions, especially after the Parthian dynasty of the Arsacidae gave place to the Sassanidae, 226. The Armenian Arsacidae continued to reign till 428. Then for about 200 years Armenia was subject to the Sassanidae of Persia. In 637 the Arabian caliphs first invaded Armenia, and 10 years afterward imposed the capitation tax upon the nation. The rivalries between the courts of Damascus and Constantinople were long a source of great suffering in Armenia; but in 859 the Mohammedan court set up a tributary dynasty in that country, the Bagratides, of Jewish origin, as already noticed, who reigned there till 1079. Their capital was Ani, on the Akhurian, a few miles S. E. of Kars. A branch of the Bagratides reigned at Xars from 961. There was also a third Armenian kingdom about this time, that of Vashburagan, with Van for its capital. These little kingdoms, though inferior to the Byzantine empire in population, are said to have surpassed it commercially, industrially, and financially. But after various changes and disasters there came in 1049 the bloody and complete destruction of Ardzen, near the modern Erzerum, by the Seljukian Turks under Toghrul, which was followed by the similar destruction of Ani under his successor. One by one the Armenian kings migrated with their people, and their kingdoms soon ceased to exist, though another, established in the Cilician Taurus in

1080 by Rupen, lasted till it was conquered by the Egyptian Mamelukes in 1375. The Armenian nationality was now extinguished; Armenia itself, devastated by Genghis Khan and about 1390 by Tamerlane, afterward received as conquerors first the Turcomans and then the Osmanli Turks, while the Kurds, the Persians, and the Russians have at different times taken possession of certain portions.—The Armenians are now widely scattered, yet they everywhere retain their own language, customs, and habits, with a special love of their country, are extensively engaged in commercial and industrial pursuits, and possess great influence, particularly in Russia and Turkey. Their present number is variously estimated at from $2\frac{1}{2}$ to 10 or even 12 millions. Probably there are $2\frac{1}{2}$ million Armenians in the Turkish empire alone.

ARMENIAN CHURCH. According to the Armenians, the early patriarchal religion existed in Armenia till about 1700 B. C.; then Assyrian influence brought in Sabaism, which about 725 B. C. became Magism; and this after Alexander's conquest was confusedly united with Grecian idolatry, to which were added Scythian superstitions and the worship of gods from India. They relate that King Abgar, afflicted with a disease resembling leprosy, besought Jesus by letter to come and cure him, and proffered him a refuge in Edessa from the Jews who sought to destroy him; that Jesus answered this letter with a written promise to send, after his departure, a disciple who should cure the king's malady and give life to him and his; that after the Saviour's ascension the disciple Thomas sent Thaddeus, one of the seventy, to Edessa; that Abgar, with many others, believed and was baptized; that Sanatrug, one of Abgar's successors, put to death Thaddeus, and also flayed alive and crucified St. Bartholomew; that Jude, Eustathius, and other preachers suffered martyrdom in Armenia; that about this time a large part of the nation was converted, but very soon persecutions produced a general relapse into idolatry till about A. D. 300; that then Gregory the Illuminator preached the gospel with wonderful success in Armenia, baptized as converts King Tiridates and thousands of his subjects, and was ordained first bishop of the Armenians by Leontius, bishop of Caesarea, about 302; that Gregory and Tiridates everywhere established schools, in which the children, especially of the heathen priests, were taught the Christian religion with the Greek and Syriac languages; and that Christian churches took the places of heathen altars, and the kingdom received a new life. The Armenians profess to have been the first nation that unitedly embraced Christianity; but a long and bloody conflict with Persian Magism followed before the nation fully secured religious liberty, A. D. 485. The Armenians received without question the decrees of the councils of Nice (325) and Ephesus (431); but those of Chalcedon (451) were formally rejected by

the Armenian bishops, though they also anathematized Eutyches, while they strenuously maintained the formula of one nature in Christ. The Armenian church has been therefore anathematized as heretical by both the Greek and Roman churches.—The Armenians agree with the Greeks in maintaining the procession of the Holy Ghost from the Father only, and in most other doctrines; but they make the sign of the cross with two fingers (in reference to the two natures made one in Christ's person), while the Greeks make this sign with three fingers (in reference to the Trinity). They baptize infants (or adults converted from Judaism or other religion), like the Greeks, by partially immersing them in the font and then thrice pouring water on their heads; but, unlike the Greeks, they admit to their communion Roman Catholics or Protestants who have been baptized by sprinkling. Like the Roman Catholics, they believe in transubstantiation, adore the host in the mass, and profess belief in seven sacraments; but their prayers of extreme unction are mingled with those of confirmation, which is performed by the priest at baptism, and they reject the Roman purgatory, though they pray for the dead. The people have the communion in both kinds, the broken bread or wafer (unleavened) being dipped in undiluted wine and laid on the tongue of the fasting communicant. They worship saints and their pictures as well as the cross; insist on the perpetual virginity of Mary; maintain baptismal regeneration and the spiritual efficacy of penances and sacraments; and regard confession to the priest and absolution as essential to salvation; but absolution is not purchased, nor are indulgences given. They have 165 fast days, when no animal food can be eaten; 14 great fast days, observed more strictly than the Lord's day; and more minor feasts than days of the year. Their church services are performed in the ancient Armenian language. They have nine grades or orders of clergy, viz.: the catholicos, bishop, priest, deacon, subdeacon, porter, reader, exorcist, and candle lighter. The monks live according to the rule of St. Basil. There are no regular lay monks among them. The principal Basilian convent is at Etchmiadzin. There are two grades among the priests: the vartabeds (doctors or teachers), who must remain unmarried, and are again subdivided into two classes; and the parish priests, who must be married before attaining the rank of subdeacon. The bishops are generally elected from the vartabeds, and only in rare instances, by special dispensation of the catholicos or patriarch, from the monks. The metropolitans or archbishops are distinguished from the bishops only by a higher rank and certain honorary rights, but not by superior jurisdiction. At the head of the entire hierarchy is the catholicos; he resides in the convent of Etchmiadzin, in the province of Erivan, which since 1828 has been under the rule of Russia. His authority as head of the entire church is recognized by all Arme-

nians except the adherents of the patriarch of Aghtamar on Lake Van, who since the 12th century has claimed the title of catholicos, but is recognized only by two towns and 30 villages, and had in the second half of the 17th century eight or nine bishops under his jurisdiction. Besides the patriarch of Aghtamar, the Armenian church has patriarchs at Sis, Constantinople, and Jerusalem, all of whom acknowledge the higher ecclesiastical rank of the catholicos of Etchmiadzin. The patriarchate of Sis embraces the churches of Armenia Minor, Cappadocia, and Cilicia, under the jurisdiction of about 23 bishops. The patriarchate of Jerusalem embraces the pashalics of Damascus, Aera, and Tripolis, and the island of Cyprus, and has 14 suffragan bishops. The patriarch of Constantinople has been since 1461 the civil head of all the Armenians in Turkey, and under his direct ecclesiastical jurisdiction are all the dioceses of Turkey, except those belonging to the patriarchates of Sis and Jerusalem. According to the reorganization agreed upon by the provincial council of Constantinople in 1830, the patriarchate of Constantinople embraces 18 archiepiscopal dioceses, with 35 suffragan bishops. One of the archbishops resides in Egypt. The patriarch of Constantinople, who takes rank with the great pashas of the empire, is elected by the ecclesiastical heads and the notables of the Armenian community in Constantinople. The notables were till 1839 chiefly wealthy bankers; but since then high officials of the Turkish government have obtained the ascendancy. Though of an inferior rank to the catholicos, the patriarch of Constantinople is in all other respects entirely independent, and even the name of the catholicos is no longer mentioned in the liturgical books used in Constantinople. Under the direct jurisdiction of the catholicos are the Armenians of Russia and Persia. In the former country the Armenian churches are by a ukase of 1836 divided into six dioceses (archbishoprics), with eight suffragan bishoprics or vicariates. Persia has an archbishop at Ispahan, with a suffragan bishop at Calcutta in India; and an archbishop at Tabreez with two suffragan bishops. The catholicos is at present elected by his synod, all the members of which reside at Etchmiadzin, and the election must be confirmed by the Russian government. The entire population connected with the Armenian church is estimated at about 3,000,000.—The United Armenians, also called Armeno-Catholics, are those who acknowledge the supremacy of the pope of Rome. As early as 1318 Pope John XXII. appointed a Dominican monk to be their archbishop at Soldania in Persian Armenia (afterward at Nakhtchevan). At the council of Florence (1439) a nominal union between the Roman and Armenian churches was effected, but it was not ratified. For centuries, however, there have been Armenians in Persia, Poland, Transylvania, Turkey, &c., acknowledging the pope and agreeing doctrinally

with the Roman Catholic church, but retaining their own usages, such as the communion in both kinds and the marriage of the priests. They have had a patriarch in Cilicia since 1742. The monks of St. Anthony, who have an abbot on Mount Lebanon, and the Mekhitarists, whose labors have been conspicuous in Armenian literature, are the principal monks among them. They are estimated to number 15,000 in Constantinople and 100,000 in the Turkish empire. According to the "Papal Almanac" for 1872, the Armeno-Catholic church has one patriarch (of Cilicia), five archbishoprics in Turkey and one (Lemberg) in Austria, eleven bishoprics in Turkey and one (Ispahan) in Persia. The papal bull *Reversurus*, dated July 12, 1867, which without consulting the Armenian bishops made important changes in the constitution of the Armeno-Catholic church and in its relations to Rome, called forth a violent opposition. At a national synod held in 1869 the majority of the bishops protested against the bull; and when the patriarch of Cilicia, Hassun, the head of the church, attempted to carry out the provisions of this bull, the bishops declared (Feb. 14, 1871) the election of Hassun, which had taken place in 1866, to have been illegal, and elected Archbishop Bahdarian of Diarbekir as patriarch of Cilicia. The new patriarch, with all the bishops and priests who had taken part in the election, was excommunicated by the pope on Nov. 2, 1871. This fate was toward the close of 1872 shared by all the members of the church who refused to recognize the authority of the patriarch Hassun and the decrees of the Vatican council. The excommunicated portion of the church has put itself in communication with the Old Catholics of Germany.—The Protestant Armenians have arisen within the last 50 years. An Armenian priest, Debajy Oghlu, living at Constantinople, about 1760 wrote a book, which was circulated in manuscript, on the errors of the church, praising Luther, severely chastising both priests and people for their superstition and vice, and testing every principle and ceremony by the Bible. The British and Russian Bible societies published and circulated (1813-'23) thousands of Bibles and Testaments in the ancient Armenian language, with the approval of the catholicoi of Etchmiadzin. They also published (1822-'3) the New Testament in Armeno-Turkish (Turkish in Armenian characters) and modern Armenian; but the Armenian patriarch and other clergy refused to sanction these translations. In 1830-'31 the Rev. Messrs. Eli Smith and H. G. O. Dwight, sent by the American board of commissioners for foreign missions, explored Armenia itself. The same board had had for several years a mission in Syria, where several Armenian ecclesiastics were converted. In 1831 the Rev. William Goodell, who went to Syria in 1823, established a mission of the board at Pera, a suburb of Constantinople, and was joined in 1832 by Mr. Dwight. These and other American missionaries who subsequently joined

them directed their efforts especially to the enlightenment and reformation of the Armenian nation, and, though bitterly opposed by the patriarch and other Old Armenians whose cooperation they sought, gradually extended their operations and influence through the empire, giving religious instruction, translating the Scriptures, preparing and distributing religious and educational works, establishing schools, promoting religious liberty, &c. In 1843 Ova-gim, a young Armenian who had in a fit of passion professed Mohammedanism and afterward returned to his former faith, was be-headed publicly at Constantinople by the Turkish authorities; but this led to the British minister's demanding and with the help of other foreign ministers obtaining from the sultan a written pledge that the death penalty should not be applied to such cases. But the opposition to the evangelical movement among the Armenians became still more violent. June 21, 1846, the Armenian patriarch finally excommunicated and anathematized all who remained firm to their evangelical principles, and decreed that the anathema should be annually read in all Armenian churches in the empire. July 1, 1846, the first evangelical Armenian church of Constantinople was formed, with 40 members, including females, and one week later Mr. Apisoghom Khatchaduryan was ordained its pastor. Similar churches were formed the same summer at Ismid (Nicomedia), Adabazar, and Trebizond. Nov. 15, 1847, the native Protestants were officially recognized as constituting a separate and independent community, and in November, 1850, the sultan gave to the native Protestants of Turkey a charter placing them on an equality with the older Christian organizations, and providing for a head or agent (a layman) nominated by their regular ballot, and appointed by the Porte, and also for national, provincial, and local councils chosen by themselves, to regulate their own affairs. The *Hatti-Humayum* or *Hatti-Sherif*, issued by the sultan in February, 1856, placed them on a legal equality with Moslems. In 1859 the appointment of a Protestant Armenian censor by the Turkish government relieved the Protestants from annoyances proceeding from the Old Armenian censor. The mission of the American board to the Armenians of Turkey has now grown into four distinct missions, to European, western, central, and eastern Turkey, the first having special reference to the Bulgarians, the other three to the Armenians. In the three Armenian missions there were reported, in January, 1872, 37 ordained and 63 unordained (mostly female) American missionaries, 16 stations and 184 out stations, 75 churches with about 3,800 church members, 19,411 registered Protestants, nearly 50 native pastors and as many licensed preachers, several theological and training schools and classes with over 130 pupils, 115 pupils in girls' boarding schools, and 5,657 pupils in 197 common schools.

ARMENIAN LANGUAGE AND LITERATURE. The ancient Armenian language, which is still the literary and church idiom of the Armenians, belongs to the Indo-European family, is enriched very considerably from the Sanskrit, abounds in gutturals, and has strength, flexibility, compass, and capability of expressing thought by evolving new terms from itself. The conversion of the nation to Christianity led to the introduction of certain words from the Greek, and impressed on the language a new character in several respects; the Persian and Turkish conquests produced other changes. The modern or spoken Armenian dialects differ very considerably from the ancient—the Ararat or eastern dialect less, however, than the Constantinopolitan or western dialect—chiefly in the disuse of certain words, the introduction of new words and phrases, and a change in grammatical forms, collocations of words, and idiomatic expressions. The alphabet consists of 38 letters, 36 of which were invented by the monk Mezrob about 409, and the other two added in the 12th century. In the form of the substantives generally no distinction is made to indicate gender; but besides the ordinary cases, nominative, genitive, dative, accusative, ablative, and instrumental, there are two others called the narrative and circumlocutory, formed by prefixes. The adjective, when not closely connected with the substantive, is similarly declined, and changes its form to denote the comparative degree; but the superlative is generally shown by writing the adjective twice, or by prefixing an adverb like the English *most*. The verbs, divided according to their vowels into three conjugations, and having a passive voice, vary their forms to denote the present and imperfect, have two future and two aorist tenses, of peculiar form, and the usual compound tenses formed with an auxiliary verb. The other parts of speech present no noteworthy peculiarities.—Ancient Armenian literature, older than the introduction of Christianity, is now limited to a few fragments of ancient songs preserved by Moses of Chorene. With Christianity there came into Armenia a taste for Greek literature. Previous to the invention of the Armenian alphabet the language had been written in Greek, Persian, or Semitic characters; but Mezrob now instituted schools in which the new alphabet was taught, and with Isaac the catholicos sent learned men to Edessa, Constantinople, and elsewhere, to translate foreign works into Armenian. The most important result of this was the Armenian translation of the Bible by Isaac and Mezrob, begun from the Syriac, but finally made from the Greek, usually assigned to A. D. 411, but apparently completed after the council of Ephesus (431). This translation, still in use, is of much critical and more religious value, and the oldest Armenian book extant. It was first printed at Amsterdam in 1666, under the care of Bishop Uschan, and has been often reprinted. In 1805 Zohrab and the Me-

khitarists published at Venice an improved edition of this Bible from manuscript authorities, Zohrab's improved text of the New Testament having appeared there in 1789. The influence of Mezrob's Bible was so great that the Armenian language suddenly attained a high state of perfection and regularity, and the 5th century became the golden age of its literature. Moses of Chorene or Khoren—who studied Greek at Alexandria, and after returning to Armenia became an archbishop, and died about 488 at the reputed age of 120 years—is considered by the Armenians their first classical writer. His history or chronicle of Armenia from the time of Haig to the death of Mezrob and Isaac (printed in London in 1736, with a Latin translation) is his most famous work, and next to Mezrob's Bible the most ancient authentic Armenian book. He also wrote on rhetoric and geography, and perhaps translated into Armenian the *Chronicon* of Eusebius (Venice, 1818; Latin, Milan, 1818). Contemporary with Moses of Chorene were Elisha or Eghishe, an Armenian bishop, who wrote a history of the religious wars of Vartan (a prince to whom he was secretary) with the Persians (Neumann's English translation, London, 1830), David the philosopher, &c. Armenian historical literature throws much light on the history not only of Armenia, but of all the neighboring nations (Persians, Parthians, Tartars, Arabs, &c.), and deserves much more attention than it has received. The recent history of Armenia by the vartabed Michael Tchamtchean (3 vols. 4to, Venice, 1786; afterward abridged in Armenian, Armeno-Turkish, and English) is probably their most valuable historical work in the past 500 years. The catholicos Nerses Klayetsi, who died at an advanced age in 1173, was distinguished as a theologian, sacred orator, and poet. His nephew, Nerses Lampronetsi, was a homiletical and liturgical writer. The Mekhitarists of San Lazaro, near Venice, have done much since 1717 for Armenian literature, preparing and publishing editions of the Bible and of many other works, in addition to those named above; as a history of Armenian literature by their abbot Sonal (1829), works on grammar, arithmetic, geography, &c., in ancient Armenian, a semi-monthly Armenian newspaper, translations of French, Italian, German, English, and American books, &c. There are other Armenian printing offices and newspapers at Constantinople and elsewhere. Peshimaljean prepared about half a century ago a good grammar and dictionary of the ancient Armenian language. Another learned Armenian composed a Persian dictionary (in Persian, Armenian, and Turkish), which was published at Constantinople about the same time. But before the mission of the American board was commenced (1831), comparatively little was done for the languages actually spoken or read by the Armenians. Even Peshimaljean's school had only a spelling book and one or two

other first books in the modern Armenian. But in 1861 the missionaries had translated the whole Bible into both the Armeno-Turkish and modern Armenian languages, and had published many religious, educational, and other works. Much literary progress has since been made among all the Armenians. At the close of 1871 13 newspapers—3 of them dailies, 3 tri-weeklies, and 7 weeklies (one of which issues a daily bulletin)—were published in Constantinople for Armenians.

ARMIN, Robert, an English player, author, and associate of Shakespeare. His name appears in the original list of the performers of Shakespeare's plays, given in the first folio edition of his works. He translated a small Italian novel, "The Italian Taylor and his Boy," and wrote a dramatic piece entitled "The History of the Two Maids of More Clacke;" and he is alluded to by Nash in 1592 as a writer of stories and ballads. His only work which at present has interest is entitled "A Nest of Ninnies, simply of themselves, without Compounds. *Stultorum plena sunt omnia.* By Robert Armin, 1608." Only a single copy of the original edition remains, which is in the Bodleian library. It was reprinted by the Shakespeare society in 1842.

ARMINIANS, a religious sect deriving their name from James Arminius (see **ARMINUS**), before whose death (1609) the Reformed in Holland were divided into Arminians and Gommarists, the doctrine of predestination being the prominent point raised between them. The Gommarists were supralapsarians, and demanded strict Calvinism in doctrine and the independence of the church in regard to the state; the Arminians held that the decree to save regarded the elect as believers, but they advocated Biblical simplicity in doctrine, a peaceful spirit in the church, and a subjection of the church to the state. After the death of Arminius, Jan Uytenbogaert, preacher at the Hague, and Simon Episcopius, Gomar's successor as professor at Leyden in 1612, became the Arminian leaders. But the strife now assumed a political aspect. Jan van Olden Barneveldt and Hugo Grotius, who favored the Arminians, influenced the states general to declare a 12 years' truce with Spain (1609), in opposition to the wishes of Prince Maurice of Orange, who was stadtholder, and were thereupon charged with being traitors and in the pay of Spain; while they, in turn, regarded Maurice as seeking supreme dominion with the subversion of liberty. The Arminians in 1610 set forth their doctrinal views in a remonstrance addressed to the states of Holland and West Friesland, and were hence called Remonstrants; and their opponents, who presented a counter-remonstrance, were called Contra-Remonstrants. The states general made fruitless attempts at conciliation by recommendations of mutual forbearance, and by the conferences at the Hague (1611) between six Remonstrant pastors and six Contra-Remonstrants, and at

Delft (1613), where three appeared on each side; but finally, urged on by Maurice and the Contra-Remonstrants, who were now in the majority, they convoked a national synod at Dort in 1618, before which Episcopius and other Remonstrants were summoned. The Arminian views presented in the remonstrance, and afterward at Dort, were comprehended in these five points: 1. God, by an eternal and immutable decree in Jesus Christ his Son, before the foundation of the world, determined to save in Christ, for Christ's sake, and through Christ, those out of the fallen human race who by the Holy Spirit's grace believe in this same Son of his; but, on the other hand, to leave those who are not converted in sin and subject to wrath, and to condemn them. 2. Therefore Jesus Christ died for each and all, yet with this condition, that no one may in fact enjoy that remission of sins except the faithful man. 3. Man indeed has not from himself saving faith, but must necessarily be born again and renewed in Christ by his Holy Spirit, that he may be able to understand, think, wish, or perform anything good. 4. This grace of God is the beginning, increase, and perfection of everything good; so indeed that all good works which we can think out are to be ascribed to the grace of God in Christ, which is not irresistible in the mode of its operation; for it is said of many that they resisted. 5. Those who are engrafted into Jesus Christ by true faith, and are therefore partakers of his life-giving Spirit, have abundantly of the means by which to fight against Satan and their own flesh and obtain the victory, but yet through the aid of the Holy Spirit's grace; but Jesus Christ by his Spirit stands by them in all temptations, reaches out his hand, and, provided they are ready for the contest and seek his aid, and fail not of their own duty, confirms them; but whether they themselves cannot by their own negligence desert the beginning of their being in Christ, make shipwreck of conscience, and fall from grace, must be deeply pondered out of the Holy Scripture before they could teach it with full tranquillity of mind and full assurance. This fifth point was afterward modified, and the Arminians maintained explicitly the possibility of falling from grace. Before the synod of Dort was convened, the republican leaders, Barneveldt, Grotius, and Hogerbeets, were imprisoned; and the first of these was subsequently beheaded. The synod began its sessions Nov. 13, 1618, and closed them May 29, 1619. Disputes early arose as to the mode in which the Remonstrants should defend themselves; criminations were answered with recriminations; the Remonstrants were ejected from the synod (Jan. 14, 1619), condemned as corruptors of the true religion, and suspended from office till they should make satisfaction; and the Calvinistic doctrine of predestination was formally confirmed, but in such language as to be accepted by infralapsarians. The states

general soon confirmed the decree of the synod. The Remonstrants were deprived of their sacred and civil offices; their preachers were banished if they did not renounce all exercise of their ecclesiastical functions; many went with Episcopius to Antwerp, others to Hollarstein, others to France, &c. After Prince Maurice's death (1625) their banished clergy began to return. Amsterdam and Rotterdam became their chief seats in Holland; the former city allowed them to build a church in 1630, and since that time they have not been molested. Episcopius published at Antwerp in 1622 the Remonstrants' Confession of Faith, which was widely circulated and held in high repute; but he expressly guarded against its being taken as of binding authority. He became in 1634 the first professor of theology in their gymnasium at Amsterdam, where Curellaicus, Pollenburg, Limborch, Le Clerc, Cattenburgh, Wetstein, &c., have also been professors. These and others set aside human confessions and took the Bible alone as their guide, ascribing special importance to its practical directions. They denied the ordinary doctrine of original sin, modified the doctrine of the Trinity, and some of them were regarded as closely allied with the Socinians.—Arminianism has been widely prevalent in the established church of England from the time of Laud to the present; but under this common name have been ranged many shades of doctrine, Trinitarian, Pelagian, Socinian, &c., agreeing in little except their opposition to Calvinism. After the rise of Methodism, Whitefield and others avowed themselves distinctively Calvinistic, while Wesley and his followers embraced the views of Arminius. The most complete work of Arminian theology in English, and the text book prescribed for Methodist Episcopal preachers in the United States, is the "Theological Institutes" of the Rev. Richard Watson. The Lutherans, Unitarians, General Baptists, and Free-will Baptists, many in the Protestant Episcopal church of the United States, and the Wesleyan Methodist churches, are all classed as Arminians, in the sense of being opposed to the Calvinistic doctrine of predestination.

ARMINIUS (in German improperly called Hermann), prince of the Cherusci, a German tribe, and the liberator of Germany, born about 16 B. C. In his youth he became a Roman citizen of the equestrian order, and served on the Danube as leader of an auxiliary body of the Cherusci. On his return, finding his country smarting under the oppressions of the Roman commander Varus, he organized an extensive conspiracy. Professing great friendship for Varus, and admiration for Roman civilization, he induced the general to distribute a large part of his force in small detachments among different tribes, under the plea of maintaining better order among the Germans. The news, true or false, of an insurrection having reached the Romans, Varus marched in October, A. D. 9, from the Weser toward the Teutoburg forest (now partly

in the principality of Lippe and partly in Prussia). Arminius, against whom Varus had in vain been warned, now gave the signal for insurrection. The Romans scattered in the interior were murdered, and the main body, which was encumbered with vast trains of baggage and camp followers, found itself surrounded on all sides. The Romans fought their way for three days, until almost all were exterminated, Varus taking his own life. From among the prisoners, the chiefs, civil and military, were sacrificed to the gods, the rest enslaved. This destruction of three Roman legions filled Rome with grief and shame. For several days Augustus would only utter the words, "Varus, give me back my legions!" More than four years elapsed before Germanicus marched from Gaul to avenge the fallen; he advanced into Germany, but returned, after a short campaign, the same year. Among the Germans dissensions soon prevailed. Arminius carried off Thusnelda (celebrated afterward in German minstrelsy), daughter of Segestes, a Germanic chief friendly to the Romans, and married her, but she soon fell again into the hands of her father. Next year (15) Germanicus entered with fresh troops, relieved Segestes, who was besieged by Arminius, and liberated him, but Thusnelda was made a Roman slave. Arminius now called the Cherusci and other tribes to arms. Germanicus led against him 80,000 men in three divisions, and a large fleet on the Weser and the Ems. Arminius retreated until he had drawn the Romans into narrow passes, and then attacked them with such fury that Germanicus, having lost his cavalry, was obliged to retreat, and reached his vessels with difficulty; four legions under Ciccina scarcely escaped total destruction previous to crossing the Rhine. The next spring Germanicus returned with an army of 100,000 men and about 1,000 vessels on the rivers. Beyond the Weser, between the present towns of Hameln and Rinteln, on a plain called Woman's Meadow, was fought the greatest battle between the Germans and Romans. The Germans were beaten, but nevertheless renewed the struggle the next day, and obliged the victorious Romans to retreat. This was the last time that Roman armies invaded Germany beyond the Rhine, and Arminius is therefore justly called the liberator. According to a legend, he disappeared in a mysterious manner during an interview on a half-built bridge with his brother Flavus, who remained attached to the Romans and tried to persuade Arminius to return to them. But history says that Arminius, being proclaimed chief by the Cherusci and numerous other tribes, attacked Marbod (Maroboduus), chief of the Marcomanni, his rival in pretensions to supreme power, who was supported by Inguomer, the uncle of Arminius. After a terrible struggle in Saxony, and a great undecided battle, Marbod was abandoned by many of his partisans, returned to Bohemia, and finally fled to the Romans, leaving Armin-

ius in undisputed possession. Arminius finally excited discontent by the strictness of his rule, and perished by the treachery of one of his relations. His wife Thusnelda, their son Thumelicus, born in captivity, and Segmund, brother of Thusnelda, appeared as prisoners in the triumphal cortège of Germanicus in Rome, A. D. 16. The lineage of the Cherusean princes was extinct, with the exception of Italiens, son of Flavius, who in 47 was given up by the Romans to the Cherusei at their request. Tacitus says that the name of Arminius was alive in the songs of the "barbarians of his time," and it still lives in Germany. It was the theme of many patriotic songs during the rising in 1813 against the domination of Napoleon.

ARMINIUS, James (in Dutch, **JACOB HARMZEN** or **HEERMANSZOON**), a Dutch theologian, born at Oudewater, South Holland, in 1560, died at Leyden, Oct. 19, 1609. In his infancy his father died, leaving him with his brother and sister to his mother's care. Theodore Æmilins, an expriest, undertook to educate him, but died when Arminius in his 15th year was studying at Utrecht. The boy found another patron in his countryman Rndolph Snellius, who took him to Marburg in Hesse; but he soon returned to the ruins of Oudewater, where the Spaniards had massacred his mother, brother, sister, and other relatives, with nearly all the inhabitants. Then he went back on foot to Marburg; but as the new university at Leyden was now opened, he returned to Holland the same year, and the Reformed pastor at Rotterdam, Peter Bertius, sent him with his own son to Leyden, where he remained six years. The magistrates of Amsterdam engaging (1582) to bear his expenses in studying for the ministry, he gave a written bond to devote himself after ordination to the ministry in their city, and to no other work or place without the burgomaster's sanction. He went at once to Geneva, where Beza was lecturing; soon gave offence there by advocating the system of Ramus in opposition to the reigning philosophy of Aristotle; went then to Basel, where he lectured publicly, and the theological faculty offered him a doctorate, which he declined on account of his youth; returned to Geneva in 1583, and continued his study of divinity; went in 1586 to Padua, and heard Zabarella's lectures in philosophy; visited Rome and some other places in Italy; and stopped again at Geneva, where Beza gave him a commendatory letter. Summoned to Amsterdam, he found himself, in the autumn of 1587, in disfavor with his patrons for having visited Italy without their consent, and, as was reported, kissed the pope's foot, become intimate with Bellarmine and the Jesuits, and abjured the reformed religion; but he exculpated himself, was licensed to preach by the Amsterdam classis, received a unanimous call, and was ordained pastor in Amsterdam, Aug. 11, 1588. Here he passed 15 years in a very popular and successful ministry. He married in 1590, and had seven sons and two

daughters, only two of whom—Lawrence, a merchant, and Daniel, a distinguished physician—reached full maturity. Soon after his settlement in the ministry, Arminius was led toward the theological system which bears his name (see **ARMINIANS**), through a controversy which arose at Delft in 1588 respecting Calvin's and Beza's views on predestination. He was urged and consented to undertake the defence of Beza, but suspended his purpose on account of difficulties respecting some of Beza's and Calvin's positions. He gave public expositions of Rom. vii. and ix. (1591-'3), presenting the views afterward published in his treatises on those chapters, and producing in each case considerable excitement. In 1597 he conferred with Francis Junius, professor of divinity at Leyden, and had a long and friendly epistolary discussion with him respecting predestination, which is published in the works of Arminius. He opposed in 1600 the annual subscription of the Dutch creed and catechism by all the ministers. During the plague of 1602 he assiduously cared for the sick and bereaved. Junius died of this plague about the end of 1602, and the curators of the university soon chose Arminius to be professor in his place; but only after repeated applications of the curators, aided by leading men in the states, would the authorities of Amsterdam permit him to leave, April 15, 1603. The charge of his being a Pelagian led to a conference at the Hague, May 6, 1603, with Francis Gomar, primary professor of theology at Leyden, who declared the charge unsupported. He was the first to receive (July 11, 1603) the degree of D. D. from the university of Leyden, and delivered on the occasion his oration on the priesthood of Christ. He introduced his course the same year with three finished orations on the object of theology, on its author and end, and on its certainty. A fifth oration, on reconciling religious dissensions among Christians, he delivered Feb. 8, 1606, on resigning the annual office of rector of the university. A conflict had already begun between the two colleague professors, Arminius and Gomar. Arminius publicly maintained, Feb. 7, 1604, that "predestination, as it regards the thing itself, is the decree of the good pleasure of God in Christ, by which he resolved within himself from all eternity to justify, adopt, and endow with everlasting life, to the praise of his own glorious grace, believers on whom he had decreed to bestow faith;" and defined "reprobation to be a decree of the wrath or severe will of God, by which he resolved from all eternity to condemn to eternal death unbelievers, who, by their own fault and the just judgment of God, would not believe, for the declaration of his wrath and power." At the end of October Gomar, who was a supralapsarian, publicly attacked these positions, and was sustained by the principal teachers in the universities. Arminius replied. Not only the students and ministers, but the

whole republic, now became involved in a religious war. Another trouble arose in respect to the word *av-θeoc* as applied to the Son of God, Arminius admitting its applicability in the sense of "one who is truly God," but not in the sense, which some maintained, of "one who is God of himself." Arminius was also charged with favoring the brief catechism published by the ministers of Gouda in 1607, which, it was alleged, would open the floodgates to all sorts of error. Arminius and his friend Jan Uytenbogaert, preacher at the Hague, called upon the states general in 1608 to convene a general synod, before which Arminius might defend himself. After a conference between Arminius and Gomar before the supreme court the same year, the states general, advised by this tribunal, enjoined the parties to drop their dispute, and teach nothing against the creed or catechism. But the disputes went on. Oct. 30, 1608, Arminius made before the states at the Hague his famous declaration (*Declaratio*) of sentiments on 10 different points, viz.: predestination, the providence of God, the free will of men, the grace of God, the perseverance of the saints, the assurance of salvation, the perfection of believers in this life, the divinity of the Son of God, the justification of man before God, and the revision of the Dutch confession and the Heidelberg catechism. The states general as a body were now inclined to favor Arminius. Another conference in 1609 between Arminius and Gomar, aided by four other ministers on each side, was soon interrupted by the sickness of Arminius, who, exhausted in body and mind, and deeply wounded by evil reports, sank under a complication of fever and other diseases. He was an energetic and eloquent preacher, and personally attractive. Mosheim styles him "a man whom even his enemies commend for his ingenuity, acuteness, and piety." Many have been called Arminians whose views differed widely from his, and many have been called Calvinists whose views agreed mainly with his. His works have been published in Latin (*Jacobi Arminii Opera Theologica*, 4to, Leyden, 1629), and translated into English by Nichols and Bagnall (3 vols. 8vo, Auburn, 1853).

ARMITAGE, Edward, an English painter, born in London in 1817. He was a pupil of Paul Delaroche, whom he assisted in the decoration of the "Hemicycle" in the school of fine arts at Paris. He first brought himself into notice in England as a competitor for prizes at the several exhibitions of cartoons and specimens of fresco painting at Westminster hall, London, in 1843-'5; and he subsequently executed several frescoes in the new houses of parliament. He has produced many large and elaborate historical works, and is one of the most prolific painters of the modern English school. His range of subjects embraces sacred and profane history, allegory, and battle scenes. Some of his Scriptural pieces are conceived with originality, but he is deficient as a colorist.

ARMOR, a defensive covering for the head, body, and limbs, used as a protection in battle. Armor of some kind seems to have been used by almost every civilized and savage people, from the earliest historic times till the gradual improvement in firearms rendered it useless as a means of defence wherever these were employed. Even of late years body armor has been worn by cuirassiers in the armies of several nations of continental Europe, but it has proved worthless as a protection against bullets from the present perfected small arms.—In the most ancient times defensive armor was undoubtedly made of skins; but history gives little account of this, and the oldest complete and authentic records we possess speak of metal armor. From the earliest times of the Old Testament (a complete panoply being described in 1 Sam. xvii.) to the fall of the Roman empire, bronze or brass seems to have been the material used for helmets and body armor by all the principal nations of antiquity, while their shields and bucklers were sometimes made of wood covered with leather or studded with brass, of bull's hide or of wickerwork covered with hide, as well as of solid bronze like their armor and weapons; for the ancients were long ignorant of the art of tempering steel, though they tempered bronze to a wonderful hardness. Even when the Romans, at an early date, introduced steel for weapons, their defensive armor remained of bronze; and the same was the case with that of other nations.—The armor of the Hellenic chiefs, as described by Homer, and, with slight modifications, that of the Greek warriors during all the period of their country's greatness, consisted of a crested helmet which could be drawn down so as to partly

cover the face; a small breastplate, worn so low as to leave the whole clavicular region bare; a plated waistband, from which hung a short kilt or petticoat of cloth or leather covered with narrow metallic plates; and greaves or

sheaths of solid metal for the legs from knee to ankle; the greaves were moulded to the form of the legs, and sometimes covered the knee. The Greeks carried at first large circular shields, covering almost the whole man; afterward smaller ones of the same shape.—The Roman soldiery wore armor almost exactly like that just described, save that they carried oblong instead of round shields. After a time, too, they rejected the greaves, and fought with the legs bare. So few changes were made in the

Roman Armor. (From Trajan's Column.)

armor itself, however, that even in the time of the crusades the soldiers of the eastern empire still wore exactly such equipments as are pictured in the bass-reliefs of Trajan's column.—The oriental nations adopted at an early period an armor made of overlapping scales of metal sewn upon leather, and fitting the whole body of the wearer. They also clothed their horses in this armor. The Sarmatians especially are said to have worn this armor, if indeed they did not introduce it.—Such were the principal kinds of armor in use among the leading nations of eastern Europe and of the Orient; but it was in western Europe that the complete defensive armor afterward used, which reached its perfection in the middle ages, had its origin. A manuscript of the reign of Charles the Bald (A. D. 860) shows the armor of the western nations which had once been Roman provinces, or had come in contact with Romans, to have been similar to the Roman dress just described. But soon afterward great changes began. We have little to show the manner of these changes, but we find their result, two centuries later, shown in the Bayeux tapestry, executed some time after the invasion of England by William the Conqueror (1066). This shows the Saxons to have adopted an armor consisting of a long tunic reaching to the knee, and made of leather upon which were sewed stout metal rings, close together. They wore conical steel caps. The Normans wore similar

tunics or shirts, divided so that they fell on each side the horse of a mounted knight; but they made their armor of actual mail, formed

Norman Spearman. (From the Bayeux Tapestry.)

of rings woven together like those in a modern curb chain; they wore long sleeves, which the Saxons had not, and long hose woven of rings. The Norman shield was in shape like a modern smoothing-iron. The fact that this flexible mail might be driven into the flesh by a hard

Full Suit of Chain Mail, Time of the Early Crusades.

blow, in spite of the heaviest lining, led to the introduction of plate armor. First the square-topped helmet of the templars was adopted, covering the whole face, and having a door opening laterally on hinges. Then poldrons, or plates covering the shoulders, *genouillères*, or

knee-pieces, of jointed steel splints, and plate shoes, were added to the mail; and this was the suit of armor, of the best and most approved construction, so late as to the time of the third crusade of Richard Cœur de Lion and Philip

armor was gradually improved, until it reached its perfection during the reign of Henry VII. In the suit of that time we find perhaps the greatest security and beauty ever combined in armor. The whole suit is fluted; the neck is

Armor comprising both Mail and Plate, A. D. 1370.

Augustus, in 1189, both of which monarchs are represented in their great seals equipped and armed exactly as described. Without detailing the gradual but constant encroachment of plate armor upon mail, it is enough to say that

it lasted for 200 years, adding piece by piece, until in the beginning of the 15th century we find complete suits of plate, casing the wearer in steel from head to foot. From that time this

ral form; the back of the neck is protected by flexible plates; and the whole of the headpiece is made to adapt itself to every movement. The horse's head is guarded by the *chamfron*,

to which are added the *manifaire*, protecting the crest and arch of the neck, the *poitrelet* of solid plates covering the counter, and the *croupier*, also of solid steel, extending over the whole rump of the animal from the castle of the saddle to the tail. These parts of the horse armor constitute what is called the *barding* proper. It was in this reign that the art of defence had so far surpassed the means of offence, that it is on record that in Italy, where the best armor, that of Milan, was made, two armies fought from 9 o'clock in the morning till 4 in the afternoon, in which battle not only no person was killed, but no one was wounded. From this date, however, the use of armor has constantly declined, and with the description given above its real history may be said to end; for piece by piece was gradually laid aside as firearms were used and improved more and more, and hand-to-hand conflicts were avoided. At the beginning of the present century the only troops who still wore defensive armor were the heavy cavalry of the Austrian, Russian, and French imperial armies, who were all cuirassiers. Napoleon I. made great use of this arm, but at Waterloo the iron-sheathed cuirassiers went down like grass before the English household troops, who wore no armor; and in the last battles of the Crimea, although there were cuirassiers in the armies of all the three belligerents, no use was made of them in the field. In the early part of our late civil war an attempt was made to introduce bullet-proof waistcoats of steel among the national troops, but they were soon laid aside.—For a detailed history of armor, see especially "A Critical Inquiry into Ancient Armour," &c., by Dr. (Sir Samuel) Meyrick (2d ed., London, 1844); also an excellent essay and catalogue in the *Catalogue des collections composant le musée d'artillerie*, by O. Penguilly l'Haridon (Paris, 1862).

ARMORICA, the name anciently given to the N. W. coast of Gaul, from the Loire to the Seine. It had a considerable fleet and carried on a large intercourse with Britain. Maximus, a Roman officer, having revolted with the legions of Britain against the emperor Gratian, A. D. 383, passed into Gaul with two Roman legions and a number of aboriginal Britons, among whom was one Conan Mariadee, to whom Maximus gave the government of Armorica. Mariadee obtained the recognition of his independence from the emperor Theodosius, and in the 5th century thousands of British Celts came over, rather than remain under the hated Saxon yoke. They found in Armorica a hospitable reception, and a dynasty akin to them in race. The descendants of Conan Mariadee successfully repelled the Danish, Norwegian, and Irish pirates from the coasts of Armorica, and also, on the land side, the various German tribes who invaded and ravaged Gaul. During the 5th and 6th centuries it was the most peaceful and prosperous part of that country. The Christian religion was

early propagated there. Bishops of Dol, Quimper, and Vannes are recorded at the end of the 4th century, and the annals of Armorica preserve a long roll of Celtic saints whose names are not known elsewhere. From the influx of Britons Armorica about the 6th century began to be called Brittany (Bretagne).

ARMS, instruments or weapons of offence, as opposed to defensive armor. Arms may in this sense be separated into two broad divisions of ancient and modern, reckoning the latter from the adaptation of gunpowder to purposes of war; and each of these may be again distinguished into missiles and weapons for hand-to-hand encounter. It is evident that offensive arms were prior in their invention and use to defensive coverings. In the earliest wars recorded in history, missiles were the principal weapons used. The bow (see **ARCHERY**) and the javelin were in the period chronicled in the Old Testament the favorite weapons of the Assyrians, Medes, Persians, Parthians, and other oriental races; while their instruments for close fight were merely weak, straight daggers, *acinaeces*, which word has been falsely translated scimitars. In the heroic wars, as described by Homer, missiles were still, in the hands of the leading chiefs and heroes, the most important weapons; a ponderous spear, hurled from the hand, and rarely if ever used to thrust with as a pike, being the instrument which began nearly all the duels of the champions, although they were often ended by the short sword. The masses, indeed, seem to have fought in phalanx or close column with the pike, or *sarissa*, afterward the arm of the free Greeks of the republican cities, and of the barbaric kingdoms of Macedonia and upper Hellas. This was 24 feet long, and the spear-men held it in both hands, having their persons obliquely covered by the great round shield worn upon the left arm. The tactic on which the success of this arm depended was a closely serried phalanx, ordinarily of 12 or 24, occasionally of 50 files in depth. If the enemy succeeded in breaking this phalanx, the men had recourse to their swords, which, however, seldom proved of much use after the spears had given way.—The weapons of the Romans were a short, massive javelin, 6 feet long, including the triangular steel head of 18 inches, which they were wont to hurl into the lines of their enemy at 10 or 15 paces distant, and a short two-edged broadsword, probably in the first instance of Spanish origin and manufacture. This latter instrument, with which they were trained to stab rather than to strike, was that with which Rome cut her way to universal empire. Her tactic, adapted to its use, was a loose array of open lines, each man standing three feet from his left and right hand comrades, so that he had a clear space of six feet in which to manage his sword and buckler, and fighting as it were a duel or single combat, hand to hand, with his immediate opponent, over whom his peculiar weapon, his sin-

gular skill in its use, and his incessant drilling in athletic exercises of all sorts, gave him immense advantage. With the Greeks and Romans infantry was the front and principal feature of their armies. In cavalry they were weak, and in the period of their greatest empire archery and slingers were contemptuously disregarded.—But with the decline of the Roman empires, especially that of the East, a new arm of the service took the lead in the steel-clad cavalry of the middle ages. Infantry, with but two exceptions, the English and the Swiss, were almost powerless against it. The arms of these feudal troops were the lance, the mace, the battle-axe, and the two-handed sword; but it is to the first that they owed their success. This was a ponderous weapon of 18 feet in length, balanced by the great weight of its butt end, which was often nearly a foot in diameter at 20 inches from the extremity, having a notch cut out to admit the upper arm of the champion, which steadied it as it was laid in rest, supported by a projecting iron catch attached to the right-hand side of the knight's corset. With this weapon, protruding 10 feet beyond their horse's chest, sheathed in panoply which defied any missiles which in that day could be brought against it, with the sole exception of the English clothyard arrow, infantry could seldom resist their shock. The arms of the infantry of this time were, besides the famous bows of the Englishmen, the bills—something similar to a short heavy scythe blade set erect on a shaft four feet long—leaden mallets, and long knives of the Anglo-Norman archers; the pikes and halberds of the Swiss, which won them the day of Sempach, and did them good service at Morat, Granson, and Nancy, when the Austrian and Burgundian chivalry had dismounted; the crossbows of the Genoese; and the spears of the Scottish foot, who fought like the Greeks in phalanx.—Such were the distribution and relative importance of different arms during the greater part of the middle ages, and until the battle of Pavia, in 1525. This date marks the division between ancient and modern arms; for although gunpowder had been long before invented, it was at Pavia that the matchlock was first used in such a form as to make it of any practical value. Even then it was a most imperfect and awkward weapon, fired from a rest. From this time firearms were improved, and the ancient offensive weapons, though they held their own for a considerable period, passed slowly out of use. The range of firearms was still very limited, and the accuracy of aim imperfect; and, till the musket was combined with the bayonet, the musketeer had no means of defending him self either against charging horse, or against infantry with long weapons, at close quarters, and he was therefore of necessity protected by pikemen. But at the beginning of the 17th century the bayonet was added to the arquebuse or musket, which had become from a matchlock a firelock, and now united

in itself the properties of both pike and gun, and could be used indiscriminately as a missile or a weapon at close quarters. From this time, so rapid was the progress made in firearms, and so general their adoption, that the bullet soon became the arbiter of every battle, the combatants seldom coming to sufficiently close quarters to permit the use of weapons of the old form. The American war of independence and the French wars of the revolution brought the rifle, which was by no means a new weapon—for the principle of rifling or screwing barrels, as it was then called, and its effect on the bullet, were known and used even in matchlocks as early as the 16th century—into general notice, and the invention of percussion doubled even its utility. From this time began that wonderful series of improvements in rifled small arms and cannon which has made the military rifle of to-day a most formidable weapon. The invention of the simple modern percussion lock, of the Minié rifle bullet, of revolving pistols, and especially of breech-loading firearms of every kind, has enormously increased the means of offensive warfare. (See ARTILLERY, CANNON, GUN, GUNNERY, GUNPOWDER, MUSKET, PISTOL, RIFLE.)

ARMSTRONG, a W. county of Pennsylvania, intersected and partly bounded by Alleghany river; area, 750 sq. m.; pop. in 1870, 43,382. The surface is undulating and the soil generally fertile. The Pennsylvania canal passes through its southern extremity. Its most valuable mineral productions are iron, salt, and coal. In 1870 the county produced 298,194 bushels of wheat, 135,257 of rye, 680,314 of Indian corn, 883,846 of oats, 33,192 tons of hay, 126,068 lbs. of wool, and 964,020 of butter. Capital, Kittanning.

ARMSTRONG, John, an American officer in the revolutionary war, born at Carlisle, Pa., in 1758, died at Red Hook, Dutchess county, N. Y., April 1, 1843. At the age of 18 he entered the army as a volunteer, and at the battle of Princeton was one of Gen. Mercer's aids, and bore him in his arms from the field when he had received his death wound. He afterward became a favorite of Gen. Gates, and served under him, with the rank of major, through the remainder of the war. During the winter of 1782-'3, while the army was encamped at Newburgh, great anxiety was felt as to the arrearages of pay, and the half pay promised to those officers who should serve through the war. After an unsuccessful application to congress, a meeting of officers was called anonymously for the 11th of March, 1783, to discuss their grievances. An anonymous address was issued, in which the writer exhorted his comrades to refuse to perform further military duty during the war, or to lay down their arms on the return of peace, unless their just demands were complied with. Washington immediately issued a call for a similar meeting on the 15th, for the discussion of their claims, which was followed by another anonymous address, construing the

action of Washington into an approval of the course previously proposed by the writer. At this meeting Washington addressed the officers with great feeling, assuring them of his ardent desire to coöperate with them in obtaining the ends which they had in view, but begging them not to follow the dangerous advice of the writer of the addresses. His eloquence was successful, and he afterward obtained from congress what the soldiers required. Armstrong wrote these anonymous productions at the request of many of his fellow officers, and although Washington had greatly blamed their author at the time, he afterward changed his opinion. Gen. Armstrong was subsequently secretary of state of Pennsylvania, and a member of the old congress. In November, 1800, he was chosen U. S. senator from New York, and in 1804 was sent as minister to France, where he served with ability, at the same time acting as minister to Spain. He returned home in 1810. At the commencement of the war of 1812 he received a brigadier general's commission, and the command of the district which included the city of New York. In the following year he was appointed secretary of war, and removed the war department to Sackett's Harbor. He incurred much blame for the capture of Washington in 1814, but very unjustly, as Gen. Winder, to whom the defence of the district had been intrusted, was appointed by the president in direct opposition to his advice. Gen. Armstrong's indignation at Mr. Madison for taking no steps to relieve him of this undeserved disgrace ended in his resignation. He wrote two treatises on farming and gardening, a criticism of Gen. Wilkinson's memoirs, biographical sketches, and a history of the war of 1812. He also partly prepared a history of the American revolution.

ARMSTRONG, John, a British physician, poet, and miscellaneous writer, born in Castleton parish, Roxburghshire, about 1709, died in 1779. His father was a clergyman. He studied at the university of Edinburgh, and after receiving his medical diploma settled in London, where he published anonymously "An Essay for Abridging the Study of Physic" (1735), ridiculing the ignorance of the apothecaries. In 1737 he published an outrageously indecent poem entitled "The Economy of Love." In 1744 appeared "The Art of Preserving Health," a didactic poem whose merits were greatly overrated. In 1760, through the influence, as it is said, of John Wilkes, he was made physician to the army in Germany, and held that office until the peace of 1763. His remaining published writings include a volume of "Sketches or Essays," a collection of short poems under the title of "Miscellanies," a "Short Ramble through France and Italy," and a volume of medical essays.

ARMSTRONG, John, an English physician and author, born at Bishop-Wearmouth, May 8, 1784, died in London, Dec. 12, 1829. He graduated at Edinburgh university, and practised

at Sunderland, where he wrote a work on "Typhus" (1816), which had a rapid sale throughout the kingdom. In 1818 he removed to London, where he failed to pass his examination before the college of physicians; but as that institution was exceedingly unpopular in the profession, his rejection was ascribed to jealousy, and he was soon afterward elected physician to the fever hospital. In 1821 he united with Mr. Grainger in founding the Webb street school of medicine, where his lectures were exceedingly popular. His chief defect was immoderate egotism. He regarded himself as a great reformer in the healing art, and ridiculed almost all medical learning except his own. His lectures, edited by Joseph Rix, were published in 1834.

ARMSTRONG, Sir William George, an English engineer and inventor, born at Newcastle-upon-Tyne, Nov. 26, 1810. He was educated at Bishop-Auckland, and early busied himself with experiments in the physical sciences, the construction of models, &c. At his father's wish he began the study of law, though he had no inclination for that profession; he passed successfully through his preliminary studies, and became a partner in the firm with which he had been placed. But he devoted all his leisure to mechanical pursuits, and in 1838 produced his first invention, an important improvement in the hydraulic engine; and in 1845 he invented a hydraulic crane, which immediately proved one of the most useful machines of its kind. In 1842 he invented a machine for the production of electricity from steam. Mr. Armstrong was made a member of the royal society in 1846, and in the same year was one of a company to establish the Elswick iron works, at which his cranes are manufactured, with large engines, iron bridges, &c. In 1854, during the Crimean war, the attention of Mr. Armstrong was attracted to improvements in ordnance, and somewhat later he produced the plan of the breech-loading cannon which bears his name. For this and his other inventions he was knighted in 1859. The construction of iron-clad ships of war led him to make in 1861-'2 numerous experiments on the penetrability of iron plates; in the course of these he came to the conclusion that shot fired at moderate distances, from muzzle-loading, smooth-bored cannon of large calibre, possess greater power of penetrating and crushing iron plates than the projectiles of the breech-loading rifled ordnance. This result has excited much comment from eminent artillery officers in England and elsewhere. Since 1858 Sir William Armstrong has been engineer of the war department, and superintendent of the manufacture of cannon at the government foundry at Woolwich, and also manufactures a large number at his own works at Elswick.

ARMY, the organized body of armed men which a state maintains for the purposes of war. Of the armies of ancient history, the first of

which we know anything positive is that of Egypt. Its epoch of glory coincides with the reign of Rhamses II. (Sesostris), and the paintings and inscriptions relating to his exploits on the monuments of his reign form the principal source of our knowledge on Egyptian military matters. The warrior caste of Egypt, according to Herodotus, was divided into two classes, *hermotybi* and *calasirii*, of which the first was 160,000 and the other 250,000 strong, in their best times. These two classes were distinguished from each other merely by their age or length of service, so that the *calasirii*, after a certain number of years, passed into the *hermotybi* or reserve. The whole army was settled in a sort of military colonies, an ample extent of land being set apart for each man as an equivalent for his services. These colonies were mostly situated in the lower part of the country, where attacks from the neighboring Asiatic states were to be anticipated; a few colonies only were established on the upper Nile, the Ethiopians not being very formidable opponents. The strength of the army, as shown by monumental records, lay in its infantry, and particularly in its archers. Besides these latter there were bodies of foot soldiers, variously armed and distributed into battalions, according to their arms, spearmen, swordsmen, clubmen, slingers, &c. The infantry was supported by numerous war chariots, each manned by two men, one to drive and the other to use the bow. Cavalry does not figure on the monuments. One solitary drawing of a man on horseback is considered to belong to the Roman epoch, and it appears certain that the use of the horse for riding and of cavalry became known to the Egyptians through their Asiatic neighbors only. That at a later period they had a numerous cavalry, acting, like all cavalry in ancient times, on the wings of the infantry, is certain. The defensive armor of the Egyptians consisted of shields, helmets, and breastplates, or coats of mail, of various materials. The mode of attacking a fortified position showed many of the means and artifices known to the Greeks and Romans. They had the *testudo* and battering ram, the *vinea* and scaling ladder; that they, however, also knew the use of movable towers, and that they undermined walls, as Sir G. Wilkinson maintains, is a mere supposition. From the time of Psammeticus a corps of Greek mercenaries was maintained; they were also colonized in lower Egypt.—Assyria furnishes us with the earliest specimens of those Asiatic armies which for above 1,000 years struggled for the possession of the countries between the Mediterranean and the Indus. There, as in Egypt, the monuments are our principal sources of information. The infantry appear armed like the Egyptian, though the bow seems less prominent, and the arms offensive and defensive are generally of better make. Spear, bow, sword, and dagger are the principal weapons. Assyrians in the army of Xerxes are also represented with iron-mounted

clubs. The defensive armament consisted of a helmet (often very tastefully worked), a coat of mail of felt or leather, and a shield. The war chariots still formed an important portion of the army; each had two occupants, and the driver had to shelter the bowman with his shield. Many of those who fight in chariots are represented in long coats of mail. Then there was the cavalry, which here we meet with for the first time. In the earliest sculptures the rider mounts the bare back of his horse; later on, a sort of pad is introduced, and in one sculpture a high saddle is depicted, similar to that now used in the East. The cavalry can scarcely have been very different from that of the Persians and later eastern nations—light, irregular horse, attacking in disorderly swarms, easily repelled by a well armed, solid infantry, but formidable to a disordered or beaten army. Accordingly, it figured in rank below the charioteers, who appear to have formed the aristocratic arm of the service. In infantry tactics some progress toward regular movements and formations in ranks and files appears to have been made. The bowmen either fought in advance, where they were always covered each by a shield-bearer, or they formed the rear rank, the first and second ranks, armed with spears, stooping or kneeling to enable them to shoot. In sieges they certainly knew the use of movable towers and mining; and from a passage in Ezekiel, it would almost appear that they made some sort of mound or artificial hill to command the walls of the town—a rude beginning of the Roman *agger*. Their movable and fixed towers, too, were elevated to the height of the besieged wall, and higher, so as to command it. The ram and vinea they used also; and, numerous as their armies were, they turned whole arms of rivers into new beds in order to gain access to a weak front of the attacked place, or to use the dry bed of the river as a road into the fortress. The Babylonians seem to have had armies similar to those of the Assyrians, but special details are wanting.—The Persian empire owed its greatness to its founders, the warlike nomads of the present Farsistan, a nation of horsemen, with whom cavalry took at once that predominant rank which it has since held in all eastern armies, up to the recent introduction of modern European drill. Darius Hystaspis established a standing army in order to keep the conquered provinces in subjection, as well as to prevent the frequent revolts of the satraps or civil governors. Every province thus had its garrison, under a separate commander; fortified towns were occupied by detachments. The provinces had to bear the expense of maintaining these troops. To this standing army also belonged the guards of the king, 10,000 chosen infantry (called the "immortals"), resplendent with gold, followed on the march by a long train of carriages, with their harems and servants, and of canals with provisions, besides 1,000 halberdiers, 1,000 horse guards, and numerous war chariots, some

of them armed with scythes. For expeditions of magnitude this armament was considered insufficient, and a general levy from all the provinces of the empire took place. The mass of these various contingents formed a truly oriental army, composed of the most heterogeneous parts, varying among themselves in armament and mode of fighting, and accompanied by immense trains of baggage and innumerable camp followers. It is to the presence of these latter that we must ascribe the enormous numbers of the Persian armies as estimated by the Greeks. The soldiers, according to their respective nationality, were armed with bows, javelins, spears, swords, clubs, daggers, slings, &c. The contingent of every province had its separate commander; they appear from Herodotus to have been divided by tens, hundreds, thousands, &c., with officers to command each decimal subdivision. The command of large corps or of the wings of the army was generally given to members of the royal family. Among the infantry the Persian and the other Aryan nations (Medes and Bactrians) formed the élite. They were armed with bows, spears of moderate size, and a short sword; the head was protected by a sort of turban, the body by a coat covered with iron scales; the shield was mostly of wickerwork. Yet this élite, as well as the rest of the Persian infantry, was generally beaten whenever it was opposed to even small bodies of Greeks, and its unwieldy and disorderly crowds appear quite incapable of any but passive resistance against the incipient phalanx of Sparta and Athens; witness Marathon, Thermopylæ, Plataea, and Mycæ. The war chariots, which in the Persian army appear for the last time in history, might be useful on level ground against such a motley crowd as the Persian infantry themselves were; but against a solid mass of pikemen, such as the Greeks formed, or against light troops taking advantage of inequalities of ground, they were worse than useless. The least obstacle stopped them. In battle the horses got frightened, and, no longer under command, ran down their own infantry. As to the cavalry, the earlier periods of the empire give us little proof of its excellence. There were 10,000 horse on the plain of Marathon—a good cavalry country—yet they could not break the Athenian ranks. In later times it distinguished itself at the Granicus, where, formed in one line, it fell on the heads of the Macedonian columns as they emerged from the fords of the river, and broke them before they could deploy. It thus successfully opposed Alexander's advanced guard, under Ptolemy, for a long while, until the main body arrived and the light troops manœuvred on its flanks, when, having no second line or reserve, it had to retire. But at this period the Persian army had been strengthened by the infusion of a Greek element, imparted by the Greek mercenaries, who, soon after Xerxes, were taken into pay by the king; and the cavalry tactics dis-

played by Memnon on the Granicus are so thoroughly un-Asiatic that we may, in the absence of positive information, at once ascribe them to Greek influence.—The armies of Greece are the first of the detailed organization of which we have ample and certain information. With them the history of tactics, especially infantry tactics, may be said to begin. In Athens every free-born man was liable to military service. The holders of certain public offices alone, and in the earlier times the fourth or poorest class of freemen, were exempt. Every youth on attaining his 18th year was obliged to do duty for two years, especially in watching the frontiers. During this time his military education was completed; afterward he remained liable to service up to his 60th year. In case of war the assembled citizens fixed the number of men to be called out; in extreme cases only were the *levées en masse* (*panstratia*) resorted to. The *strategi*, ten of whom were annually elected by the people, had to levy these troops and to organize them, so that the men of each tribe, or *phyle*, formed a body under a separate phylarch. These officers, as well as the taxiarchs, or captains of companies, were equally elected by the people. The whole of this levy formed the heavy infantry (*hoplitæ*) destined for the phalanx or deep line formation of spearmen, which originally formed the whole of the armed force, and subsequently, after the addition of light troops and cavalry, remained its mainstay—the corps which decided the battle. The phalanx was commanded by a general with the title of *strategus*, and was formed in various depths; we find phalanxes 8, 12, and 25 men deep, mentioned in Grecian history. The armament of the *hoplitæ* consisted of a breastplate or corslet, helmet, oval target, spear, and short sword. The forte of the Athenian phalanx was attack; its charge was renowned for its furious impetus, especially after Miltiades at Marathon had introduced the quickening of the pace during the charge, so that they came down on the enemy with a run. On the defensive, the more solid and closer phalanx of Sparta was its superior. While at Marathon the whole force of the Athenians consisted of a heavy-armed phalanx of 10,000 *hoplitæ*, at Plataea they had, besides 8,000 *hoplitæ*, an equal number of light infantry. The tremendous pressure of the Persian invasions necessitated an extension of the liability to service; the poorest class, that of the *thetes*, was enrolled. They were formed into light troops (*gymneta*, *psili*); they had no defensive armor, or a target only, and were supplied with a spear and javelins. With the extension of the Athenian power, their light troops were reinforced by the contingents of their allies, and even by mercenary troops. Acarnanians, Ætolians, and Cretans, celebrated as archers and slingers, were added. A class of troops intermediate between them and the *hoplitæ* was formed, the *peltasta*, armed like the light in-

fantry, but capable of maintaining a position. They were of little importance until after the Peloponnesian war, when Iphicrates reorganized them. The light troops of the Athenians enjoyed a high reputation for intelligence and quickness both in resolution and in execution. On several occasions, probably in difficult ground, they even successfully opposed the Spartan phalanx. The Athenian cavalry was introduced at a time when the republic was already rich and powerful. The mountainous ground of Attica was unfavorable to this arm, but the neighborhood of Thessaly and Bœotia, countries rich in horses, and consequently the first to form cavalry, soon caused its introduction in the other states of Greece. The Athenian cavalry, first 300, then 600, and even 1,000 strong, was composed of the richest citizens, and formed a standing corps even in time of peace. They were a very effective body, extremely watchful, intelligent, and enterprising. Their position in battle, as well as that of the light troops, was generally on the wings of the phalanx. In later times the Athenians also maintained a corps of 200 mercenary mounted archers (*hippotoxote*). The Athenian soldier up to the time of Pericles received no pay. Afterward two oboli (besides two more for provisions, which the soldier had to find) were given, and sometimes even the hoplite received as much as two drachms. Officers received double pay, cavalry soldiers threefold, generals fourfold. The corps of heavy cavalry alone cost 40 talents (about \$40,000) per annum in time of peace, during war considerably more. The order of battle and mode of fighting were extremely simple. The phalanx formed the centre, the men locking their spears and covering the whole front with their row of shields. They attacked the hostile phalanx in a parallel front. When the first onset was not sufficient to break the enemy's order, the struggle had to hand with the sword decided the battle. In the mean time the light troops and cavalry either attacked the corresponding troops of the enemy, or attempted to operate on the flank and rear of the phalanx, and to take advantage of any disorder. In case of a victory they undertook the pursuit; in case of defeat they covered the retreat as much as possible. They were also used for reconnoitring expeditions and forays, they harassed the enemy on the march, especially when he had to pass a defile, and they tried to capture his convoys and stragglers. The phalanx always operated as a whole; its subdivisions into smaller bodies had no technical significance; their commanders had no other task than to see that the order of the phalanx was not broken, or was quickly restored. At the beginning of the Peloponnesian war, the Athenian army mustered 13,000 hoplitæ for field service, 61,000 (the youngest and the oldest soldiers) for garrison duty, 1,200 horsemen, and 1,600 archers. According to Bœckh's calculations, the force sent against Syracuse numbered 38,560 men, and

reinforcements despatched afterward, 26,000. The ruin of this expedition utterly exhausted the resources of Athens.—Sparta was preëminently the military state of Greece. The Spartans directed their attention mostly to strength, endurance, and hardiness. They valued steadiness in the ranks, and military point of honor, more than intelligence. As long as the phalanx decided the battle, the Spartan in the long run had the best of it. In Sparta every freeman was enrolled in the army lists from his 20th to his 60th year. The ephors determined the number to be called out, and they were generally chosen among the middle-aged men, from 30 to 40. As in Athens, the men belonging to the same tribe or locality were enrolled in the same body of troops. The organization of the army was based upon the confraternities (*enomotia*) introduced by Lycurgus, two of which formed a *pentecostys*; two of these were united into a *lochos*, and eight or four lochi into a *mora*. This was the organization in Xenophon's time; in former periods it appears to have varied. The strength of a mora is variously stated at from 400 to 900 men, and their number at one time was said to be 600. These various bodies of free Spartans formed the phalanx; the hoplitæ composing it were armed with a spear, a short sword, and a shield fastened round the neck. Later on, Cleomenes introduced the large Carian shield, fastened by a string on the left arm, and leaving both hands of the soldier free. The Spartans considered it disgraceful for their men to return after a defeat without their shields; the preservation of the shield proved the retreat to have been made in good order and in a compact phalanx, while single fugitives, running for their lives, of course had to throw away the clumsy shield. The Spartan phalanx was generally eight deep, but sometimes the depth was doubled by placing one wing behind the other. The men appear to have marched in step; some elementary evolutions were also in use, such as changing front to the rear by facing the men about, advancing or retiring a wing by wheeling, &c.; but they would seem to have been introduced at a later period only. In their best times, the Spartan phalanx, like that of Athens, knew the parallel front attack only. The ranks on the march were distant from each other six feet, in the charge three feet, and in a position receiving the charge only a foot and a half, from rank to rank. The army was commanded by one of the kings, who, with his suite (*damasia*), occupied a position in the centre of the phalanx. Afterward, the number of the free Spartans having considerably decreased, the strength of the phalanx was kept up by a selection from the subjected Peræci. The cavalry was never stronger than about 600 men, divided into troops (*ulami*) of 50 men; it merely covered the wings. There was besides a body of 300 mounted men, the élite of the Spartan youth, but they dismounted in battle, and formed a

sort of bodyguard of hoplite around the king. Of light troops, there were the *skiritæ*, inhabitants of the mountains near Arcadia, who generally covered the left wing; the hoplite of the phalanx, besides, had Helot servants, who were expected in battle to do duty as skirmishers; thus, the 5,000 hoplite at Plataea brought 35,000 Helot light troops with them, but of the exploits of these latter we find nothing stated in history.—The simple tactics of the Greeks underwent considerable changes after the Peloponnesian war. At the battle of Leuctra, Epaminondas had to oppose with a small force of Thebans the far more numerous and hitherto invincible Spartan phalanx. The plain, parallel front attack here would have been equivalent to certain defeat, both wings being outflanked by the longer front of the enemy. Epaminondas, instead of advancing in line, formed his army into a deep column, and advanced against one wing of the Spartan phalanx, where the king had taken his station. He succeeded in breaking through the Spartan line at this, the decisive point; he then wheeled his troops round, and moving on either hand, he himself outflanked the broken line, which could not form a new front without losing its tactical order. At the battle of Mantinea the Spartans formed their phalanx with a greater depth, but nevertheless the Theban column again broke through it. Agesilaus in Sparta, and Timotheus, Iphierates, and Chabrias in Athens, also introduced changes in infantry tactics. Iphierates improved the peltastæ. They were armed with a small round target, strong linen corslet, and long spear of wood. Chabrias made the first ranks of the phalanx, when on the defensive, kneel down to receive the enemy's charge. Full squares, and other columns, &c., were introduced, and accordingly deployments formed part of the elementary tactics. At the same time, greater attention was paid to light infantry of all kinds; several species of arms were borrowed from the barbarous and semi-barbarous neighbors of the Greeks, such as archers, mounted and on foot, slingers, &c. The majority of the soldiers of this period consisted of mercenaries. The wealthy citizens, instead of doing duty themselves, found it more convenient to pay for substitutes. The character of the phalanx, as the preëminently national portion of the army, in which the free citizens of the state only were admitted, thus suffered from this admixture of mercenaries who had no right of citizenship. Toward the approach of the Macedonian epoch, Greece and her colonies were as much a mart for soldiers of fortune and mercenaries as Switzerland in the 18th century. The Egyptian kings had at an early time formed a corps of Greek troops. Afterward the Persian king gave his army some steadiness by the admission of a body of Greek mercenaries. The chiefs of these bodies were regular condottieri, as much as those of Italy in the 15th century. During this period warlike engines for throwing stones, darts, and

incendiary projectiles were introduced, especially by the Athenians. Pericles already used some similar machines at the siege of Samos. Sieges were carried on by forming a line of contravallation, with ditch or parapet, round the place, investing it, and by the attempt to place the war engines in a commanding position near the walls. Mining was regularly made use of, to bring the walls down. At the assault, the column formed the *synaspismus*, the outer ranks holding their shields before them, and the inner ranks holding them over their heads, so as to form a roof (the testudo of the Romans) against the projectiles of the enemy.—While Greek skill was thus mainly directed toward shaping the flexible material of the mercenary bands into all sorts of novel and artificial formations, and in adopting or inventing new species of light troops, to the detriment of the ancient Doric heavy phalanx, which at that time alone could decide battles, a monarchy grew up which, adopting all real improvements, formed a body of heavy infantry of such colossal dimensions, that no army with which it came in contact could resist its shock. Philip of Macedon formed a standing army of about 30,000 infantry and 3,000 cavalry. The main body of the army was an immense phalanx of some 16,000 or 18,000 men, formed upon the principle of the Spartan phalanx, but improved in armament. The small Grecian shield was replaced by the large oblong Carian buckler, and the moderate-sized spear by the Macedonian pike (*sarissa*) of 24 feet in length. The depth of this phalanx varied under Philip from 8 to 10, 12, and 24 men. With the tremendous length of the pikes, each of the six front ranks could, on levelling them, make the points project in front of the first rank. The regular advance of such a long front of from 1,000 to 2,000 men presupposes a great perfection of elementary drill, which in consequence was continually practised. Alexander completed this organization. His phalanx was normally 16,384 men strong, or 1,024 in front by 16 deep. The file (*lochos*) of 16 men was conducted by a *lochagos*, who stood in the front rank. Two files formed a *diloche*, two of which made a *tetrarchy*, two of which a *taxiarchy*, two of which a *xenag* or *syntagma*, 16 men in front by 16 deep. This was the unit of evolution, the march being made in columns of *xenagies*, 16 in front. Sixteen *xenagies* (equal to eight *pentecosiarchies*, or four *chiliarchies*, or two *telarchies*) formed a small phalanx, two of which a *diphalangarchy*, and four a *tetraphalangarchy* or phalanx properly so called. Every one of these subdivisions had its corresponding officer. The *diphalangarchy* of the right wing was called *head*, that of the left wing *tail*, or *rear*. Whenever extraordinary solidity was required, the left wing took station behind the right, forming 512 men in front by 32 in depth. On the other hand, by deploying the eight rear ranks on the left of the front ranks, the extent of front could be

doubled, and the depth reduced to eight. The distances of ranks and files were similar to those of the Spartans, but the close order was so compact that the single soldier in the middle of the phalanx could not turn. Intervals between the subdivisions of the phalanx were not allowed in battle; the whole formed one continuous line, charging *en masse*. The phalanx was formed by Macedonian volunteers exclusively; though, after the conquest of Greece, Greeks also could enter it. The soldiers were all heavy-armed hoplitæ. Besides shield and pike, they carried a helmet and sword, although the hand-to-hand fight with the latter weapon cannot very often have been required after the charge of that forest of pikes. When the phalanx had to meet the Roman legion, the case indeed was different. The whole phalangite system, from the earliest Doric times down to the breaking up of the Macedonian empire, suffered from one great inconvenience; it wanted flexibility. Unless on a level and open plain, these long, deep lines could not move with order and regularity. Every obstacle in front forced it to form column, in which shape it was not prepared to act. Moreover, it had no second line or reserve. As soon, therefore, as it was met by an army formed in smaller bodies and adapted to turn obstacles of ground without breaking line, and disposed in several lines seconding each other, the phalanx could not help going into broken ground, where its new opponent completely cut it up. But to such opponents as Alexander had at Arbela, his two large phalanxes must have appeared invincible. Besides this heavy infantry of the line, Alexander had a guard of 6,000 *hypaspistæ*, still more heavily armed, with even larger bucklers and longer pikes. His light infantry consisted of *argyraspides*, with small silver-plated shields, and of numerous peltastæ, both of which troops were organized in semi-phalanxes of normally 8,192 men, being able to fight either in extended order or in line, like the hoplitæ; and their phalanx often had the same success. The Macedonian cavalry was composed of young Macedonian and Thessalian noblemen, with the addition subsequently of a body of horsemen from Greece proper. They were divided into squadrons (*ilæ*), of which the Macedonian nobility alone formed eight. They belonged to what we should call heavy cavalry; they wore a helmet and a cuirass with eussarts of iron scales to protect the leg, and were armed with a long sword and pike. The horses, too, wore frontlets of iron. This class of cavalry, the *cataphracti*, received great attention both from Philip and Alexander; the latter used it for his decisive manœuvre at Arbela, when he first beat and pursued one wing of the Persians, and then, passing behind their centre, fell upon the rear of the other wing. They charged in various formations: in line, in common rectangular column, in rhomboid or wedge-shaped column. The light cavalry had no defensive armor; it carried javelins and light

short lances. There was also a corps of *acrobalistæ* or mounted archers. These troops served for outpost duty, patrols, reconnoitring, and irregular warfare generally. They were the contingents of Thracian and Illyrian tribes, which also furnished some few thousands of irregular infantry. A new arm invented by Alexander claims our attention from the circumstance that it has been imitated in modern times—the *dimachæ*, mounted troops expected to fight either as cavalry or as infantry. The dragoons of the 16th and following centuries, as well as the light cavalry and mounted infantry of our own day, are complete counterparts to these ancient dimachæ. We have no exact information as to the success with which the dimachæ were used. The foregoing statement describes the composition of the army with which Alexander conquered the country between the Mediterranean, the Oxus, and the Sutlej. As to its strength at Arbela, it consisted of two large phalanxes of hoplitæ (say 30,000 men), two semi-phalanxes of peltastæ (16,000), 4,000 cavalry, and 6,000 irregular troops; in all about 56,000 men. At the Granicus, his force of all arms was 35,000 men, of whom 5,000 were cavalry.—The armies of the successors of Alexander show no improvements on his formations. The introduction of elephants was but of short duration; when terrified by fire, these animals were more formidable to their own troops than to the enemy. The later Greek armies, under the Achaean league, were formed partly on the Macedonian, partly on the Roman system.—Of the Carthaginian army we know no details; even the strength of the force with which Hannibal passed the Alps is disputed.—The Roman army presents us with the most perfect system of infantry tactics invented during the time when the use of gunpowder was unknown. It maintained the predominance of heavy infantry and compact bodies, but added to it mobility of the separate smaller bodies, the possibility of fighting in broken ground, the disposition of several lines one behind the other, partly as supports and reliefs, partly as a powerful reserve, and finally a system of training the single soldier which was even more to the purpose than that of Sparta. The Romans accordingly overthrew every armament opposed to them, the Macedonian phalanx as well as the Numidian horse. In Rome every citizen from his 17th to his 45th or 50th year was liable to serve, unless he belonged to the lowest class, or had served in 20 campaigns on foot, or 10 campaigns as a horseman. Generally the younger men only were selected. The drill of the soldier was very severe, and calculated to develop his bodily powers in every imaginable way. Running, jumping, vaulting, climbing, wrestling, swimming, first naked, then in full armament, were largely practised, besides the regular drill in the use of the arms and the various movements. Long marches in heavy marching order, every soldier carrying from 35 to 60 lbs., were kept up at the rate of four miles an hour.

The use of the intrenching tools, and the throwing up of intrenched camps in a short time, also formed part of the military education; and not only the recruit, but even the legions of veterans, had to undergo all these exercises in order to keep their bodies fresh and supple, and to remain inured to fatigue and want. In the best times of the republic there were generally two consular armies, each consisting of two legions and the contingents of the allies (in infantry of equal strength, cavalry double the strength of the Romans). The levy of the troops was made in a general assembly of the citizens at the capitol or on the Campus Martius; an equal number of men was taken from every tribe, which was again equally subdivided among the four legions, until the number was completed. Very often citizens, freed from service by age or their numerous campaigns, entered again as volunteers. The recruits were then sworn in and dismissed until required. When called in, the youngest and poorest were taken for the *velites*, the next in age and means for the *hastati* and *principes*, the oldest and wealthiest for the *triarii*. Every legion counted 1,200 velites, 1,200 hastati, 1,200 principes, 600 triarii, and 300 horsemen (knights); in all, 4,500. The hastati, principes, and triarii were each divided into ten *manipuli* or companies, and an equal number of velites attached to each. The velites (*rorarii*, *accensi*, *ferentarii*) formed the light infantry of the legion, and stood on its wings along with the cavalry. The hastati formed the first, the principes the second line; they were originally armed with spears. The triarii formed the reserve, and were armed with the *pilum*, a short but extremely heavy and dangerous spear, which they threw into the front ranks of the enemy immediately before engaging him sword in hand. Every manipulus was commanded by a centurion, having a second centurion for his lieutenant. The centurions ranked through the whole of the legion, from the second centurion of the last or tenth manipulus of the hastati to the first centurion of the first manipulus of the triarii (*primuspilus*), who, in the absence of a superior officer, even took the command of the whole legion. Commonly, the *primus pilus* commanded all the triarii, the same as the *primus princeps* (first centurion of first manipulus of principes), all the principes and the *primus hastatus*, and all the hastati of the legion. The legion was commanded in the earlier times in turns by its six military tribunes; each of them held the command for two months. After the first civil war, legates were placed as standing chiefs at the head of every legion; the tribunes now were mostly officers intrusted with the staff or administrative business. The difference of armament of the three lines had disappeared before the time of Marius. The *pilum* had been given to all three lines of the legion; it was now the national arm of the Romans. The qualitative distinction between the three lines, as far as it was

based upon age and length of service, soon disappeared too. In the battle of Metellus against Jugurtha, there appeared, according to Sallust, for the last time hastati, principes, and triarii. Marius now formed out of the 30 manipuli of the legion 10 cohorts, and disposed them in two lines of five cohorts each. At the same time, the normal strength of the cohort was raised to 600 men; the first cohort, under the *primus pilus*, carried the legionary eagle. The cavalry remained formed in *turme* of 30 rank and file and three decurions, the first of whom commanded the *turma*. The armature of the Roman infantry consisted of a shield of semi-cylindric shape, 4 feet by 2½, made of wood, covered with leather and strengthened with iron fastenings; in the middle it had a boss (*umbo*) to parry off spear thrusts. The helmet was of brass, generally with a prolongation behind to protect the neck, and fastened on with leather bands covered with brass scales. The breastplate, about a foot square, was fastened on a leather corslet with scaled straps passing over the shoulder; for the centurions, it consisted of a coat of mail covered with brass scales. The right leg, exposed when advanced for the sword thrust, was protected by a brass plate. Besides the short sword, which was used for thrusting more than for cutting, the soldier carried the *pilum*, a heavy spear 4½ feet wood with a projecting iron point of 1½ foot, or nearly 6 feet in all long, but 2½ inches square in the wood, and weighing about 10 or 11 lbs. When thrown at 10 or 15 paces distance, it often penetrated shield and breastplate, and almost always threw down its man. The velites, lightly equipped, carried light short javelins. In the later periods of the republic, when barbaric auxiliaries undertook the light service, this class of troops disappeared entirely. The cavalry were provided with defensive armor similar to that of the infantry, a lance, and a longer sword. But the Roman national cavalry was not very good, and preferred to fight dismounted. In later periods Numidian, Spanish, Gallic, and German horsemen supplanted it. The tactical disposition of the troops admitted of great mobility. The manipuli were formed at intervals equal to their extent of front; the depth varied from 5 or 6 to 10 men. The manipuli of the second line were placed behind the intervals of the first; the triarii still further to the rear, but in one unbroken line. According to circumstances, the manipuli of each line could close up or form line without intervals, or those of the second line could march up to fill the intervals of the first; or else, where greater depth was required, the manipuli of the principes closed up each in rear of the corresponding manipulus of the hastati, doubling its depth. When opposed to the elephants of Pyrrhus, the three lines all formed with intervals, each manipulus covering the one in its front, so as to leave room for the animals to pass straight through the order of battle. In this formation the clumsiness of the

phalanx was in every way successfully overcome. The legion could move and manœuvre, without breaking its order of battle, in ground where the phalanx durst not venture without the utmost risk. One or two manipuli at most would have to shorten their front to defile past an obstacle; in a few moments the front was restored. The legion could cover the whole of its front by light troops, as they could retire, on the advance of the line, through the intervals. But the principal advantage was the disposition in a plurality of lines, brought into action successively, according to the requirements of the moment. With the phalanx, one shock had to decide. No fresh troops were in reserve to take up the fight in case of a reverse; in fact, that case was never provided for. The legion could engage the enemy with its light troops and cavalry on the whole of his front; could oppose to the advance of his phalanx its first line of hastati, which was not so easily beaten, as at least six of the ten manipuli had first to be broken singly; could wear out the strength of the enemy by the advance of the hastati, and finally decide the victory by the triarii. Thus the troops and the progress of the battle remained in the hands of the general, while the phalanx, once engaged, was irretrievably engaged, with all its strength, and had to see the battle out. If the Roman general desired to break off the combat, the legionary organization permitted him to take up a position with his reserves, while the troops engaged before retired through the intervals, and took up a position in their turn. Under all circumstances, there was always a portion of the troops in good order, for even if the triarii were repulsed, the two first lines had reformed behind them. When the legions of Flamininus met Philip's phalanx in the plains of Thessaly, their first attack was at once repulsed; but charge following charge, the Macedonians got tired and lost part of their compactness of formation; and wherever a sign of disorder manifested itself, there was a Roman manipulus to attempt an inroad into the clumsy mass. At last, 20 manipuli attacking the flanks and rear of the phalanx, tactical continuity could no longer be maintained; the deep line dissolved into a swarm of fugitives, and the battle was lost. Against cavalry, the legion formed the *orbis*, a sort of square with baggage in the centre. On the march, when an attack was to be apprehended, it formed the *legio quadrata*, a sort of lengthened column with a wide front, baggage in the centre. This was of course possible in the open plain only where the line of march could go across the country.—In Caesar's time the legions were mostly recruited by voluntary enlistment in Italy. After the social war, the right of citizenship, and with it liability for service, had been extended to all Italy. The pay was about equal to the earnings of a laborer; recruits, therefore, were plentiful, even without having recourse to the conscription. In exceptional cases only were legions recruited

in the provinces; thus Caesar had his fifth legion recruited in the Roman Gaul, but afterward it received the Roman naturalization *en masse*. The legions were far from having the nominal strength of 4,500 men; those of Caesar were seldom much above 3,000. Levies of recruits were formed into new legions (*legiones itonum*), rather than mixed with the veterans in the old legions; these new legions were at first excluded from battles in the open field, and principally used for guarding the camp. The legion was divided into ten cohorts of three manipuli each. The names of hastati, principes, and triarii were maintained as far as necessary to denote the rank of officers according to the system indicated above; as to the soldiers, these names had lost all significance. The six centuries of the first cohort of each legion were by right present at councils of war. The centuries rose from the ranks, and seldom attained higher command; the school for superior officers was in the personal staff of the general, consisting of young men of education, who soon advanced to the rank of *tribuni militum*, and later on to that of *legati*. The armament of the soldier remained the same: pilum and sword. Besides his accoutrements, the soldier carried his personal baggage, weighing from 35 to 60 pounds. The contrivance for carrying it was so clumsy that the baggage had first to be deposited before the soldier was ready for battle. The camp utensils of the army were carried on the backs of horses and mules, of which a legion required about 500. Every legion had its eagle, and every cohort its colors. For light infantry, Caesar drew from his legions a certain number of men (*antesignani*) equally fit for light service and for close fight in line. Besides these, he had his provincial auxiliaries, Cretan archers, Balearic slingers, Gallic and Numidian contingents, and German mercenaries. His cavalry consisted partly of Gallic, partly of German troops. The Roman velites and cavalry had disappeared some time before. The staff of the army consisted of the *legati*, appointed by the senate, the lieutenants of the general, whom he employed to command detached corps, or portions of the order of battle. Caesar for the first time gave to every legion a legate as standing commander. If there were not legates enough, the quaestor, too, had to take the command of a legion. He was properly the paymaster of the army and chief of the commissariat, and was assisted in this office by numerous clerks and orderlies. Attached to the staff were the *tribuni militum*, and the young volunteers above mentioned (*contubernales, comites pratorii*), doing duty as adjutants or orderly officers; but in battle they fought in line, the same as private soldiers, in the ranks of the *cohors pratoria*, consisting of the lieutors, clerks, servants, guides (*speculatores*), and orderlies (*apparitores*) of the headquarters. The general had a sort of personal guard, consisting of veterans, who had voluntarily reenlisted on the call of their former

chief. This troop, mounted on the march, but fighting on foot, was considered the élite of the army; it carried and guarded the *vacillum*, the signal banner for the whole army. In battle, Caesar generally fought in three lines, four cohorts per legion in the first, and three in the second and third lines each; the cohorts of the second line dressed on the intervals of the first. The second line had to relieve the first; the third line formed a general reserve for decisive manœuvres against the front or flank of the enemy, or for parrying his decisive thrusts. Wherever the enemy so far outflanked the line that its prolongation became necessary, the army was disposed in two lines only. One single line (*acies simplex*) was made use of in an extreme case of need only, and then without intervals between the cohorts; in the defence of a camp, however, it was the rule, as the line was still eight to ten deep, and could form a reserve from the men who had no room on the parapet.—Augustus completed the work of making the Roman troops a regular standing army. He had 25 legions distributed all over the empire, of which eight were on the Rhine (considered the main strength of the army), three in Spain, two in Africa, two in Egypt, four in Syria and Asia Minor, six in the Danubian countries. Italy was garrisoned by chosen troops recruited exclusively in that country, and forming the imperial guard; this consisted of 12, later on of 14 cohorts; and the city of Rome had also 7 cohorts of municipal guards (*vigiles*), formed originally from emancipated slaves. Besides this regular army, the provinces had to furnish, as formerly, their light auxiliary troops, now mostly reduced to a sort of militia for garrison and police duty. On menaced frontiers, however, not only these auxiliary troops, but foreign mercenaries also, were employed in active service. The number of legions increased under Trajan to 30, under Septimius Severus to 33. The legions, besides their numbers, had names, taken from their stations (*L. Germanica, L. Italica*), from emperors (*L. Augusta*), from gods (*L. Primigenia, L. Apollinaris*), or conferred as honorary distinctions (*L. fidelis, L. pia, L. invicta*). The organization of the legion underwent some changes. The commander was now called *præfectus*. The first cohort was doubled in strength (*cohortis milliariæ*), and the normal strength of the legion raised to 6,100 infantry and 726 cavalry; this was to be the minimum, and in case of need one or more cohortes milliariæ were to be added. The cohortes milliariæ was commanded by a military tribune, the others by tribunes or *præpositi*; the rank of *centurio* was thus confined to subalterns. The admission of liberated or non-liberated slaves, natives of the provinces, and all sorts of people into the legions, became the rule; Roman citizenship being required for the prætorians in Italy only, and even there this was abandoned in later times. The Roman nationality of the army was thus very soon drowned

in the influx of barbaric and semi-barbaric, Romanized and non-Romanized elements; the officers alone maintained the Roman character. This deterioration of the elements composing the army very soon reacted upon its armament and tactics. The heavy breastplate and pilum were thrown aside; the toilsome system of drill, which had formed the conquerors of the world, was neglected; camp-followers and luxuries became necessary to the army, and the *impedimenta* (train of baggage) increased as strength and endurance decreased. As had been the case in Greece, the decline was marked by neglect of the heavy line infantry, by a foolish fancy for all sorts of light armament, and by the adoption of barbaric equipments and tactics. Thus we find innumerable classifications of light troops (*auxiliatores, excubatores, jaculatoris, excursatores, præcursoris, scutati, funditores, balistarii, tragularii*), armed with all sorts of projectiles; and we are told by Vegetius that the cavalry had been improved in imitation of the Goths, Alans, and Huns. Finally, all distinction of equipment and armament between Romans and barbarians ceased, and the Germans, physically and morally superior, marched over the bodies of the un-Romanized legions. The conquest of the West by the Germans thus was opposed by but a small remnant, a dim tradition of the ancient Roman tactics; but even this small remnant was now destroyed.—The whole of the middle ages is as barren a period for the development of tactics as for that of any other science. The feudal system, though in its very origin a military organization, was essentially opposed to discipline. Rebellions and secessions of large vassals, with their contingents, were of regular occurrence. The distribution of orders to the chiefs turned generally into a tumultuous council of war, which rendered all extensive operations impossible. Wars, therefore, were seldom directed on decisive points; struggles for the possession of a single locality filled up entire campaigns. The only operations of magnitude occurring in all this period (passing over the confused times from the 6th to the 12th century) are the expeditions of the German emperors against Italy, and the crusades, the one as resultless as the other.—The infantry of the middle ages, composed of the feudal retainers and part of the peasantry, was chiefly composed of pikemen, and mostly contemptible. It was great sport for the knights, covered with iron, to ride singly into this unprotected rabble, and lay about them with a will. A portion of the infantry was armed on the continent of Europe with the crossbow, while in England the longbow became the national weapon of the peasantry. This longbow was a very formidable weapon, and secured the superiority of the English over the French at Crécy, Poitiers, and Agincourt. Easily protected against rain, which rendered the crossbow unserviceable at times, it projected its arrow to distances above 200 yards, or not

much less than the effective range of the old smooth-bore musket. The arrow penetrated a one-inch board, and would even pass through a breastplate. Thus it long maintained its place even against the first small firearms, especially as six arrows could be shot off while the musket of that epoch could be loaded and fired once; and as late as the end of the 16th century Queen Elizabeth attempted to reintroduce the national longbow as a weapon of war. It was especially effective against cavalry; the arrows, even if the armor of the men-at-arms was proof against them, wounded or killed the horses, and the unhorsed knights were thereby disabled, and generally made prisoners. The archers acted either in skirmishing order or in line.—Cavalry was the decisive arm of the middle ages. The knights in full armor formed the first effective body of heavy cavalry, charging in regular formation, which we meet with in history; for Alexander's cataphracts, though they decided the day at Arbela, were so much an exception that we hear nothing more of them after that day. The only progress, then, which the middle ages bequeathed to us, was the creation of a cavalry, from which our modern mounted service descends. And yet, what a clumsy thing this cavalry was, is proved by the one fact that during the whole middle ages the cavalry was the heavy, slow-moving arm, while all light service and quick movements were executed by infantry. The knights, however, did not always fight in close order. They preferred duels with single opponents, or spurring their horses into the midst of the hostile infantry; thus the mode of fighting out a battle was carried back to the Homeric times. When they did act in close order, they charged either in line (one deep, the more lightly armed esquires forming the second rank) or in deep column. Such a charge was undertaken, as a rule, against the knights (men-at-arms) only of the opposing army; upon its infantry it would have been wasted. The horses, heavily laden with their own as well as their riders' armor, could run but slowly and for short distances. During the crusades, therefore, and in the wars with the Mongolians in Poland and Silesia, this immovable cavalry was constantly tired out, and finally worsted by the active light horsemen of the East. In the Austrian and Burgundian wars against Switzerland, the men-at-arms, entangled in difficult ground, had to dismount and form a phalanx even more immovable than that of Macedon; in mountain defiles, rocks and stumps of trees were hurled down upon them, in consequence of which the phalanx lost its tactical order, and was scattered by a resolute attack. Toward the 14th century a kind of lighter cavalry was introduced, and a portion of the archers were mounted to facilitate their manœuvring; but these and other changes were soon rendered useless, abandoned, or turned to different account by the introduction of that new element, which was destined to change

the whole system of warfare, gunpowder.—From the Arabs in Spain the knowledge of the composition and use of gunpowder spread to France and the rest of Europe; the Arabs themselves had received it from nations further east, who again had it from the original inventors, the Chinese. In the first half of the 14th century cannon were first introduced into European armies—heavy, unwieldy pieces of ordnance, throwing stone balls, and unfit for anything but sieges. Small arms, however, were soon invented. Perugia supplied itself in 1364 with 500 hand-guns, the barrels not more than eight inches long; they subsequently gave rise to the manufacture of pistols (so called from Pistoia in Tuscany). Not long afterward longer and heavier hand-guns (*arquebuses*) were manufactured, corresponding to our present musket; but, short and heavy in the barrel, they had but a restricted range, and the matchlock was an almost absolute hindrance to correct aim. Toward the close of the 14th century there was no military force in western Europe without its artillery and arquebusiers. But the influence of the new arm on general tactics was not yet perceptible. Both large and small firearms took a long time in loading, and what with their clumsiness and costliness, they had not superseded the crossbow by 1450.—In the mean time the general breaking up of the feudal system, and the rise of cities, contributed to change the composition of armies. The larger vassals were either subdued by central authority, as in France, or had become quasi-independent sovereigns, as in Germany and Italy. The power of the lesser nobility was broken by the central authority in conjunction with the cities. The feudal armies no longer existed; new armies were formed from the mercenaries whom the ruin of feudalism had set free to serve those who would pay them. Thus, something approaching standing armies arose; but these mercenaries, men of all nations, difficult to keep in order, and not very regularly paid, committed great excesses. In France, King Charles VII. therefore formed a permanent force from native elements. In 1445 he levied 15 *compagnies d'ordonnance* of 600 men each; in all, 9,000 cavalry, stationed in the towns of the kingdom, and paid with regularity. Every company was divided into 100 lances; a lance consisted of one man-at-arms, three archers, an esquire, and a page. Thus they formed a mixture of heavy cavalry with mounted archers, the two arms in battle acting of course separately. In 1448 he added 16,000 *frances-archers*, under four captains general, each commanding eight companies of 500 men. All the archers had crossbows. They were recruited and armed by the parishes, and free from all taxes. This may be considered the first standing army of modern times.—At the close of this first period of modern tactics, as they emerged from mediæval confusion, the state of things may be summed up as follows: The main body of the infantry, consisting of

mercenaries, was armed with pike and sword, breastplate and helmet. It fought in deep, close masses, but, better armed and drilled than the feudal infantry, it showed greater tenacity and order in combat. The standing levies and the mercenaries, soldiers by profession, were of course superior to the casual levies and disconnected bands of feudal retainers. The heavy cavalry now found it sometimes necessary to charge in close array against infantry. The light infantry was still principally composed of archers, but the use of the hand-gun for skirmishers gained ground. The cavalry remained as yet the principal arm—heavy cavalry, men-at-arms encased in iron, but no longer composed in every case of the nobility, and reduced from its former chivalrous and Homeric mode of fighting to the more prosaic necessity of charging in close order. But the unwieldiness of such cavalry was now generally felt, and many devices were planned to find a lighter kind of horse. Mounted archers, as has been stated, had in part to supply this want; in Italy and the neighboring countries the *stradioti*, light cavalry on the Turkish plan, composed of Bosnian and Albanian mercenaries, a sort of bashi-bazouks, found ready employment, and were much feared, especially in pursuits. Poland and Hungary had, besides the heavy cavalry adopted from the West, retained their own national light cavalry. The artillery was in its infancy. The heavy guns of the time were indeed taken into the field, but could not leave their position after it was once taken up; the powder was bad, the loading difficult and slow, and the range of the stone balls short.—The close of the 15th and the beginning of the 16th century are marked by a double progress; the French improved the artillery, and the Spaniards gave a new character to the infantry. Charles VIII. of France made his guns so far movable that he could not only take them into the field, but make them change their position during battle and follow the other troops in their movements, which, however, were not very quick. He thereby became the founder of field artillery. His guns, mounted on wheeled carriages and plentifully horsed, proved immensely superior to the old-fashioned clumsy artillery of the Italians drawn by bullocks, and did such execution in the deep columns of the Italian infantry, that Machiavelli wrote his "Art of War" principally in order to propose formations by which the effect of such artillery on infantry could be counteracted. In the battle of Marignano, Francis I. of France defeated the Swiss pikemen by the effective fire and the mobility of this artillery, which, from flanking positions, enfiladed the Swiss order of battle. But the reign of the pike, for infantry, was on the decline. The Spaniards improved the common hand-gun (*arquebuse*) and introduced it into the regular heavy infantry. Their musket (*haquebutte*) was a heavy, long-barrelled arm, bored for two-ounce bullets, and fired from a

rest formed by a forked pole. It sent its bullet through the strongest breastplate, and was therefore decisive against the heavy cavalry, which got into disorder as soon as the men began falling. Ten or 15 musketeers were placed with every company of pikemen, and the effect of their fire at Pavia astonished both allies and enemies. Frundsberg relates that in that battle a single shot from such a musket would bring down several men and horses. From that time dates the superiority of the Spanish infantry, which lasted for above 100 years.—The war consequent upon the rebellion of the Netherlands was of great influence on the formation of armies. Both Spaniards and Dutch improved all arms considerably. Hitherto, in the armies of mercenaries, every man offering for enlistment had to come fully equipped, armed, and acquainted with the use of his arms. But in this long war, carried on during 40 years on a small extent of country, the available recruits of this class soon became scarce. The Dutch had to put up with such able-bodied volunteers as they could get, and the government was now under the necessity of seeing them drilled. Maurice of Nassau composed the first drill regulations of modern times, and thereby laid the foundation for the uniform instruction of a whole army. The infantry began again to march in step; it gained much in homogeneity and solidity. It was now formed into smaller bodies; the companies, hitherto 400 to 500, were reduced to 150 and 200 men, 10 companies forming a regiment. The improved musket gained ground upon the pike; one third of the whole infantry consisted of musketeers, mixed in each company with the pikemen. These latter, being required for hand-to-hand fight only, retained their helmet, breastplate, and steel gauntlets; the musketeers threw away all defensive armor. The formation was generally two deep for the pikemen, and from five to eight deep for the musketeers; as soon as the first rank had fired, it retired to load again. Still greater changes took place in cavalry, and here, too, Maurice of Nassau took the lead. In the impossibility of forming a heavy cavalry of men-at-arms, he organized a body of light horse recruited in Germany, armed them with a helmet, cuirass, brassaris for the arms, steel gauntlets, and long boots; and as with the lance they would not have been a match for the heavy-armed Spanish cavalry, he gave them a sword and long pistols. This new class of horsemen, approaching our modern cuirassiers, soon proved superior to the far less numerous and less-movable Spanish men-at-arms, whose horses they shot down before the slow mass broke in upon them. Maurice of Nassau had his cuirassiers drilled as well as his infantry; he so far succeeded, that he could venture to execute in battle changes of front and other evolutions with large or small bodies of them. Alva, too, had found the necessity of improving his light horse; hitherto they had been fit for skirmishing and single combat

only, but under his direction they soon learned to charge in a body, like the heavy cavalry. The formation of cavalry remained still five to eight deep. About this time Henry IV. of France introduced a new kind of mounted service, the dragoons, originally infantry mounted on horses for quicker locomotion only; but in a very few years after their introduction they were used as cavalry as well, and equipped for this double service. They had neither defensive armor nor high boots, but a cavalry sword, and sometimes a lance; they also carried the infantry musket, or a shorter carbine. These troops did not, however, come up to the expectations which had led to their formation; they soon became a portion of the regular cavalry, and ceased to fight as infantry. In artillery the French maintained the superiority they had gained. The *prolonge* was invented by them about this time, and case shot introduced by Henry IV. The Spanish and Dutch, too, lightened and simplified their artillery, but still it remained a clumsy concern, and light, movable pieces of effective calibre and range were yet unknown.—With the 30 years' war opens the period of Gustavus Adolphus, the great military reformer of the 17th century. His infantry regiments were composed of two thirds musketeers and one third pikemen. Some regiments consisted of musketeers alone. The muskets were so much lightened that the rest for firing them became unnecessary. He also introduced paper cartridges, by which loading was much facilitated. The deep formation was done away with; his pikemen stood six, his musketeers only three deep. These latter were drilled in firing by platoons and ranks. The unwieldy regiments of 2,000 or 3,000 men were reduced to 1,300 or 1,400, in eight companies, and two regiments formed into a brigade. With this formation he defeated the deep masses of his opponents, often disposed, like a column or full square, 30 deep, upon which his artillery played with terrible effect. The cavalry was reorganized upon similar principles. The men-at-arms were completely done away with. The cuirassiers lost the brassards and some other useless pieces of defensive armor; they were thus made considerably lighter and more movable. His dragoons fought nearly always as cavalry. Both cuirassiers and dragoons were formed only three deep, and had strict orders not to lose time with firing, but to charge at once sword in hand. They were divided into squadrons of 125 men. The artillery was improved by the addition of light guns. The leather guns of Gustavus Adolphus are celebrated, but were not long retained. They were replaced by cast-iron four-pounders, so light that they could be drawn by two horses; they could be fired six times while a musketeer fired twice; two of these were attached to every regiment of infantry. Thus, the division of light and heavy field artillery was established; the light guns accompanied the

infantry, while the heavy ones remained in reserve, or took up a position for the whole of the battle. The armies of this time begin to show the increasing preponderance of infantry over cavalry. At the battle of Leipsic, Gustavus Adolphus had 19,000 infantry and 11,000 cavalry; Tilly had 31,000 infantry and 13,000 cavalry. At Lützen, Wallenstein had 24,000 infantry and 16,000 cavalry in 170 squadrons. The number of guns, too, increased with the introduction of light pieces; the Swedes often had from 5 to 12 guns for every 1,000 men; and at the battle of the Lech, Gustavus Adolphus forced the passage of the river under cover of the fire of 72 heavy guns.—During the latter half of the 17th and the first half of the 18th century, pikes and all defensive armor for infantry were finally done away with by the general introduction of the bayonet. This weapon, invented in France about 1640, had to struggle 80 years against the pike. The Austrians first adopted it for all their infantry, the Prussians next; the French retained the pike till 1703, the Russians till 1721. The flint-lock, invented in France about the same time as the bayonet, was also gradually introduced before the year 1700 into most armies. It materially abridged the operation of loading, protected to some degree the powder in the pan from rain, and thus contributed very much to the abolition of the pike. Yet firing was still so slow that a man was not expected to use more than from 24 to 36 cartridges in a battle; until in the latter half of this period improved regulations, better drill, and further improvement in the construction of small arms (especially the iron ramrod, first introduced in Prussia), enabled the soldier to fire with considerable rapidity. This necessitated a still further reduction of the depth of formation, and infantry was now formed only four deep. A species of élite infantry was created in the companies of grenadiers, originally intended to throw hand-grenades before coming to close quarters, but soon reduced to light with the musket only. In some German armies riflemen had been formed as early as the 30 years' war; the rifle itself had been invented at Leipsic in 1498. This arm was now mixed with the musket, the best shots in each company being armed with it; but out of Germany the rifle found little favor. The Austrians had also a sort of light infantry called *pandours*—Croatian and Servian irregulars from the military frontier against Turkey, useful in roving expeditions and pursuit, but, from the tactics of the day and their absolute want of drill, useless in battle. The French and Dutch created, for similar purposes, irregular infantry called *compagnies franches*. Cavalry, too, was lightened in all armies. There were no longer any men-at-arms; the cuirassiers maintained the breastplate and helmet only; in France and Sweden the breastplate was also done away with. The increasing efficiency and rapidity of infantry fire told very much against cavalry. It was soon considered perfectly useless for

this latter arm to charge infantry sword in hand; and the opinion of the irresistibility of a firing line became so prevalent that cavalry, too, was taught to rely more on its carbines than on the sword. Thus, during this period, it often occurred that two lines of cavalry maintained a firing fight against each other the same as if they were infantry; and it was considered very daring to ride up to within 20 yards of the enemy, fire a volley, and charge at a trot. Charles XII., however, adhered to the rule of his great predecessor. His cavalry never stopped to fire; it always charged, sword in hand, against anything opposing it, cavalry, infantry, batteries, and intrenchments, and always with success. The French, too, broke through the new system and recommenced relying on the sword only. The depth of cavalry was still further reduced from four to three. In artillery, the lightening of the guns, and the use of cartridges and case-shot, now became general. Another great change was that of the incorporation of this arm with the army. Hitherto, though the guns belonged to the state, the men serving them were not soldiers, but formed a sort of guild, and artillery was considered not an arm but a handicraft. The officers had no rank in the army, and were considered more related to master tailors and carpenters than to gentlemen. About this time, however, artillery was made a component part of the army, and divided into companies and battalions; the men were converted into permanent soldiers, and the officers ranked with the infantry and cavalry. The centralization and permanence of the armed contingent upon this change paved the way for the science of artillery, which under the old system could not develop itself.—The passage from deep formation to line, from the pike to the musket, from the supremacy of cavalry to that of infantry, had thus been gradually accomplished when Frederick the Great opened his campaigns, and with them the classical era of line tactics. He formed his infantry three deep, and got it to fire five times in a minute. In his very first battles at Mollwitz, this infantry deployed in line, and repelled by its rapid fire all charges of the Austrian cavalry, which had just totally routed the Prussian horse; after finishing with the cavalry, the Prussian infantry attacked the Austrian infantry, defeated it, and thus won the battle. Formation of squares against cavalry was never attempted in great battles, but only when infantry on the march was surprised by hostile cavalry. In a battle, the extreme wings of the infantry stretched round *en potence* when menaced by cavalry, and this was generally found sufficient. To oppose the Austrian pandours, Frederick formed similar irregular troops, infantry and cavalry, but never relied on them in battle, where they were seldom engaged. The slow advance of the firing line decided his battles. Cavalry, neglected under his predecessor, was now made to undergo a complete revolution. It

was formed only two deep, and firing, except on pursuit, was strictly prohibited. Horsemanship, considered hitherto of minor importance, was now cultivated with the greatest attention. All evolutions had to be practised at full speed, and the men were required to remain well closed up. By the exertions of Seydlitz, the cavalry of Frederick was made superior to any other then existing or ever existing before it; and its bold riding, close order, dashing charge, and quick rallying have never yet been surpassed. The artillery was considerably lightened, so much that some of the heavy-calibred guns were not able to stand full charges, and had therefore to be abolished afterward. Yet the heavy artillery was still very slow and clumsy in its movements, owing to inferior and heavy carriages and imperfect organization. In battle, it took up its position from the first, and sometimes changed it for a second position, more in advance; but manœuvring there was none. The light artillery, the regimental guns attached to the infantry, were placed in front of the infantry line, 50 paces in advance of the intervals of the battalions; they advanced with the infantry, the guns dragged by the men, and opened fire with canister at 300 yards. The number of guns was very large, from three to six guns per 1,000 men. The infantry, as well as the cavalry, were organized in brigades and divisions; but as there was scarcely any manœuvring after the battle had begun, and as every battalion had to remain in its proper place in the line, these subdivisions had no tactical influence. With the cavalry, a general of brigade might now and then, during a charge, have to act upon his own responsibility; but with the infantry such a case could never occur. This line formation, infantry in two lines in the centre, cavalry in two or three lines on the wings, was a considerable progress upon the deep formation of former days. It developed the full effect of infantry fire, as well as of the charge of cavalry, by allowing as many men as possible to act simultaneously; but its very perfection in this point confined the whole army, as it were, in a strait waistcoat. Every squadron, battalion, or gun had its regulated place in the order of battle, which could not be inverted or in any way disturbed without affecting the efficiency of the whole. On the march, therefore, everything had to be so arranged that when the army formed front again for encampment or battle, every subdivision got exactly into its correct place. Thus, any manœuvres to be executed had to be executed with the whole army; to detach a single portion of it for a flank attack, to form a particular reserve for the attack, with superior forces, of a weak point, would have been impracticable and faulty with such slow troops, fit only to fight in line, and with an order of battle of such stiffness. Then, the advance in battle of such long lines was necessarily executed with considerable slowness, in order to keep up the align-

ment. Tents followed the army constantly, and were pitched every night; the camp was slightly intrenched. The troops were fed from magazines, the baking establishments accompanying the army as much as possible. In short, the baggage and other train of the army were enormous, and hampered its movements to a degree unknown nowadays. Yet, with all these drawbacks, the military organization of Frederick the Great was by far the best of his day, and was eagerly adopted by all other European governments. The recruiting of the forces was almost everywhere carried on by voluntary enlistments, assisted by kidnapping; and it was only after very severe losses that Frederick had recourse to forced levies from his provinces.—When the war of the coalition against the French republic began, the French army was disorganized by the loss of its officers, and numbered less than 150,000 men. The numbers of the enemy were far superior; new levies became necessary, and were made to an immense extent, in the shape of national volunteers, of which in 1793 there must have been at least 500 battalions in existence. These troops were not drilled, nor was there time to drill them according to the complicated system of line tactics, and to the degree of perfection required by movements in line. Every attempt to meet the enemy in line was followed by a signal defeat, though the French had far superior numbers. A new system of tactics became necessary. The American revolution had shown the advantage to be gained with undisciplined troops from extended order and skirmishing fire. The French adopted it, and supported the skirmishers by deep columns, in which a little disorder was less objectionable so long as the mass remained well together. In this formation they launched their superior numbers against the enemy, and were generally successful. This new formation and the want of experience of their troops led them to fight in broken ground, in villages and woods, where they found shelter from the enemy's fire, and where his line was invariably disordered; their want of tents, field batteries, &c., compelled them to bivouac without shelter, and to live upon what the country afforded them. Thus they gained a mobility unknown to their enemies, who were encumbered with tents and all sorts of baggage. When the revolutionary war had produced in Napoleon the man who reduced this new mode of warfare to a regular system, combined it with what was still useful in the old system, and brought the new method at once to that degree of perfection which Frederick had given to line tactics, then the French were almost invincible, until their opponents had learned from them, and organized their armies upon the new model. The principal features of this new system are: the restoration of the old principle that every citizen is liable in case of need to be called out for the defence of the country, and the consequent formation of

the army, by compulsory levies of greater or less extent, from the whole of the inhabitants; a change by which the numerical force of armies was at once raised to threefold the average of Frederick's time, and might in case of need be increased to larger proportions still. Then, the discarding of camp utensils, and of dependence for provisions upon magazines, and the introduction of the bivouac and of the rule that war feeds war, increased the celerity and independence of an army as much as its numerical force was raised by the rule of general liability to serve. In tactical organization, the principle of mixing infantry, cavalry, and artillery in the smaller portions of an army, in corps and divisions, became the rule. Every division thus became a complete army on a reduced scale, fit to act independently, and capable of considerable resistance even against superior numbers. The order of battle was now based upon the column; it served as the reservoir, from which sallied and to which returned the swarms of skirmishers; as the wedge-like compact mass to be launched against a particular point of the enemy's line; as the form to approach the enemy and then to deploy, if the ground and the state of the engagement made it desirable to oppose firing lines to the enemy. The mutual support of the three arms, developed to its full extent by their combination in small bodies, and the combination of the three forms of fighting, skirmishers, line, and column, compose the great tactical superiority of modern armies. Any kind of ground thereby became fit for fighting; and the ability of rapidly judging the advantages and disadvantages of ground, and of at once disposing troops accordingly, became one of the chief requirements of a captain. And not only in the commander-in-chief, but in the subordinate officers, these qualities, and general aptness for independent command, were now a necessity. Corps, divisions, brigades, and detachments were constantly placed in situations where their commanders had to act on their own responsibility; the battlefield no longer presented its long unbroken lines of infantry disposed in a vast plain with cavalry on the wings; but the single corps and divisions, massed in columns, stood hidden behind villages, roads, or hills, separated from each other by seemingly large intervals, while but a small portion of the troops appeared actually engaged in skirmishing and firing artillery until the decisive moment approached. Lines of battle extended with the numbers and with this formation; it was not necessary actually to fill up every interval with a line visible to the enemy, so long as troops were at hand to come up when required. Turning of flanks now became generally a strategical operation, the stronger army placing itself completely between the weaker one and its communications, so that a single defeat could annihilate an army and decide a campaign. The favorite tactical manœuvre was the breaking through the ene-

my's centre with fresh troops, as soon as the state of affairs showed that his last reserves were engaged. Reserves, which in line tactics would have been out of place and would have detracted from the efficiency of the army in the decisive moment, now became the chief means to decide an action. The order of battle, extending as it did in front, extended also in depth; from the skirmish line to the position of the reserves the depth was very often two miles and more. In short, if the new system required less drill and parade precision, it required far greater rapidity, exertion, and intelligence from every one, from the lowest skirmisher as well as the highest commander; and every fresh improvement made since Napoleon tends in that direction.—The changes in the *matériel* of armies were but trifling during this period; constant wars left little time for improvements the introduction of which requires time. Two very important innovations took place in the French army shortly before the revolution. The first was the adoption of a new model of musket of reduced calibre and windage, and with a curved stock instead of the straight one previously in use. This weapon, more accurately worked, contributed a great deal toward the superiority of the French skirmishers, and remained the model upon which with trifling alterations the muskets in use in all armies up to the introduction of percussion locks were constructed. The second was the simplification and improvement of the artillery by Gribeauval. The French artillery under Louis XV. was completely neglected; the guns were of all sorts of calibres, the carriages old-fashioned, and the models upon which they were constructed not even uniform. Gribeauval, who had served during the seven years' war with the Austrians, and then seen better models, succeeded in reducing the number of calibres, equalizing and improving the models, and greatly simplifying the whole system. It was with his guns and carriages that Napoleon fought his wars. The English artillery, which was in the worst possible state when the war with France broke out, was gradually but slowly much improved; with it originated the stock-trail carriage, which has since been adopted by all continental armies, and the arrangement for mounting the foot artillerymen on the limbers and ammunition wagons. Horse artillery, invented by Frederick the Great, was much cultivated during Napoleon's period, especially by himself, and its proper tactics were first developed. When the war was over, it was found that the British were the most efficient in this arm. Of all large European armies, the Austrian is the only one which supplies the place of horse artillery by batteries in which the men are mounted on wagons provided for the purpose.—The German armies still kept up the special class of infantry armed with rifles, and the new system of fighting in extended order gave a fresh importance to this arm. It was especially cultivated and in 1838

taken up by the French, who felt the want of a long range of musket for Algiers. The *tirailleurs de Vincennes*, afterward *chasseurs à pied*, were formed, and brought to a state of efficiency without parallel. The adoption of this formation was rendered necessary by the great improvements in small arms, and especially in rifles, by which both range and precision were increased to a wonderful degree. The names of Delvigne, Thouvenot, and Minié thereby became celebrated. For the whole infantry, the percussion lock was introduced between 1830 and 1840 in most armies; as usual, the English and the Russians were the last. In the mean time, great efforts were made in various quarters still further to improve small arms, and to produce a musket of superior range which could be given to the whole of the infantry. The Prussians introduced the needle gun, a rifle arm loaded at the breech, and capable of very rapid firing, and having a long range; the invention, originated in Belgium, was considerably improved by them. This gun, although by no means the best of its class either for accuracy or range, simplicity of construction or certainty of action, was early adopted and given to their troops; it was used with great effect in the Schleswig-Holstein war, and more recently in the remarkable campaigns of the Prussians in Bohemia and France. Many military writers have expressed the opinion that the Prussians owe their great successes in their recent wars at least as much to the superiority of their artillery and small arms as to any other single cause. But this is scarcely true; for while they were probably provided with better arms than the Austrians, they were certainly inferior to the French in rifles, it being generally conceded that the *Zündnadelgewehr* or needle gun is a less efficient weapon than the Chassepot. The English were the first to arm the whole of their infantry with a superior musket, viz., the Enfield rifle, a slight alteration of the Minié; its superiority was fully proved in the Crimea, and saved them at Inkerman. But the Americans have surpassed all other nations in the invention and use of rifles and carbines. The rifled musket made in the government shops at Springfield, the Spencer and Henry magazine guns, and the Remington carbine and rifles, as well as many others which were fully tested during the civil war, are now acknowledged to be superior to any English, French, or German arms of the same class, and have been adopted by many European nations.—In tactical arrangements, no changes of importance have taken place for infantry and cavalry, if we except the great improvement of light infantry tactics by the French *chasseurs*, and the new Prussian system of columns of companies, which latter formation, with some variations, is now in general use. The formation in several European armies is nominally three deep, but in practice all nations have adopted the two-rank formation introduced by the English shortly after the

time of Napoleon I. As to cavalry, the European nations still adhere to the system of Frederick, with some slight modifications. The Americans during the civil war made great progress in the organization and use of cavalry, or more properly of mounted troops. The first regiments called into service were strictly light cavalry, but the improvements in carbines and revolvers or repeating pistols, combined with the wooded nature of the country in which they were compelled to operate, soon gave a distinctively new character to this arm. Instead of fighting on horseback, using the sabre alone or the sabre and pistol, it became necessary for the cavalry regiments to fight generally on foot; and in this they not only reached a high state of efficiency, but, under Sheridan in the east and Wilson in the west, exerted a powerful influence in bringing the war to an end. The mounted troops operating in Virginia were organized into a separate body from 10,000 to 15,000 strong, called the cavalry corps of the army of the Potomac; while those in Kentucky, Tennessee, Mississippi, and Alabama, amounting to 72 regiments, and reaching at the close of the war 35,000 efficient, were organized into one command, officially known as the cavalry corps of the military division of the Mississippi. These immense masses of mounted troops were strong enough to act independently against the communications and depots of the enemy, or in cooperation with the infantry, upon the flanks and rear of the confederate armies. In the final campaigns in Virginia, and especially at the battle of Winchester or the Opequan, in the destruction of the railroads about Richmond, particularly the South Side road, at the battle of Five Forks, in the pursuit and capture of Lee's army, in the battles of Franklin and Nashville, in the pursuit and dispersion of Hood's army, in the assault and capture of Selma, Columbus, and West Point (Ga.), in the pursuit and capture of Davis and the confederate chieftains, these corps gave proof of their extraordinary merits, not only as cavalry marching rapidly and for long distances, but as infantry fighting steadily and with great dash against infantry and artillery, assaulting and carrying earthworks, and in the performance of the various duties of active warfare. The success of these corps was doubtless greatly influenced partly by their compact and independent organization, and partly by the efficient character of their firearms, which at the end of the war were almost exclusively Spencer carbines or rifles, breech-loading magazine guns of unrivalled excellence at that time. It is believed that no well directed attack made by troops using these arms was ever known to fail, whether against cavalry, infantry, or intrenchments. (See CAVALRY.)—In artillery, considerable improvements of detail and simplification of calibres, and of models for wheels, carriages, &c., have taken place in every army. The science of

artillery has been greatly improved. All modern armies now use rifled cannon for field service, as well as for siege purposes. Field guns are made of steel and wrought and cast iron, and are of various calibres, all throwing steel or iron balls, bolts, or shells, more or less elongated; these guns are also adapted to the use of canisters of small shot, and have almost entirely replaced the smooth-bored brass guns and howitzers in actual service. The Americans, Prussians, and Belgians have been foremost in making improvements in artillery. (See ARTILLERY.)—The general organization of modern armies is very much alike. With the exception of the British and American, they are recruited by compulsory levy, based either upon conscription, in which case the men, after serving their time, are dismissed for life, or upon the reserve system, in which the time of actual service is short, but the men remain liable to be called out again for a certain time afterward. France is the most striking example of the first, Prussia of the second system. Even in England, where both line and militia are generally recruited by voluntary enlistment, the conscription (or ballot) is by law established for the militia should volunteers be wanting. In Switzerland, no standing army exists; the whole force consists of militia drilled for a short time only. The enlistment of foreign mercenaries is still the rule in some countries; the French still have their foreign legion; and England, in case of serious war, is regularly compelled to resort to this expedient. The time of actual service varies very much: from a couple of weeks with the Swiss, 18 months to 2 years with the smaller German states, and 3 years with the Prussians, to 5 or 6 years in France, 12 years in England, and 15 years in Russia. The officers are recruited in various ways. In most armies there are now no legal impediments to advancement from the ranks, but the practical impediments widely vary. In France and Austria a portion of the officers must be taken from the sergeants; in Russia the insufficient number of educated candidates makes this a necessity. In Prussia the examination for officers' commissions in peace is a bar to uneducated men; in England advancement from the ranks is a rare exception. For the remainder of the officers there are in most countries military schools, though, with the exception of France, it is not necessary to pass through them. In military and general education the Prussian officers are ahead; the English and the Russians stand lowest in both. With the exceptions named above, the equipment and armament of modern armies are now everywhere nearly the same. There is, of course, a great difference in the quality and workmanship of the material. In this respect the Russians stand lowest, and the English and Americans, where the industrial advantages at their command are really made use of, stand highest. The infantry of all armies is divided into line and light infantry. The first is the

rule, and composes the mass of all infantry; real light infantry has become much more popular since the American civil war, and the late wars between Prussia, Austria, and France, and the tendency in all armies is to the numerical increase of this force. Cavalry is divided into heavy and light everywhere except in America, where it is all light. Cuirassiers are always heavy; hussars and chasseurs, always light horse. Dragoons and lancers are in some armies light, in others heavy cavalry; and the Russians would also be without light cavalry were it not for the Cossacks. The best light cavalry in Europe is undoubtedly that of the Austrians, the national Hungarian hussars, and Polish uhlans. The same division holds good with reference to artillery. Light artillery is still subdivided into horse and foot, the first especially intended to act in company with cavalry. The Austrians have no horse artillery; the English and French have no proper foot artillery, the men being carried on the limbers and ammunition wagons.—The infantry is formed into companies, battalions, and regiments. The battalion is the tactical unit; it is the form in which the troops fight, save in a few exceptional cases. A battalion must not be too strong to be commanded by the voice and eye of its chief, nor too weak to act as an independent body in battle, even after the losses of a campaign. The strength, therefore, varies from 600 to 1,400 men; 800 to 1,000 forms the average. The division of a battalion into companies has for its object the fixing of its evolutionary subdivisions, the efficiency of the men in the details of the drill, and the more commodious economical administration. The number of companies in a battalion varies as much as their strength. The English have ten of from 90 to 120 men, the Russians and Prussians four of 250 men, the French and Austrians six of varying strength. Battalions are formed into regiments, more for administrative and disciplinary purposes and to insure uniformity of drill, than for any tactical object; in formations for war, therefore, the battalions of one regiment are often separated. In Russia and Austria there are four, in Prussia three, in France two service battalions, besides depots, to every regiment; in England, most regiments are formed, in peace, of but one battalion. Cavalry is divided into squadrons and regiments. The squadron, from 100 to 200 men, forms the tactical and administrative unit; the English alone subdivide the squadron, for administrative purposes, into two troops. There are from three to ten service squadrons to a regiment; the British have in peace but three squadrons, of about 120 horse; the Prussians four, of 150 horse; the French five, of 180 to 200 horse; the Austrians six or eight, of 200 horse; the Russians six to ten, of 150 to 170 horse. With cavalry the regiment is a body of tactical significance, as a regiment offers the means to make an independent charge, the squadrons mutually supporting each other, and

is for this purpose formed of sufficient strength, viz., between 500 and 1,600 horse. The British alone have such weak regiments that they are obliged to put four or five of them to one brigade; on the other hand, the Austrian and Russian regiments in many cases are as strong as an average brigade. The French have nominally very strong regiments, but have hitherto appeared in the field in considerably reduced numbers, owing to their poverty in horses. Artillery is formed in batteries; the formation in regiments or brigades in this arm is only for peace purposes, except in America, where it is used exclusively during war. Four guns is the least number in a battery; the Austrians have eight, and the French, Prussians, English, and Americans six guns for each battery. Rifle-men or other real light infantry are generally organized in battalions and companies only, not in regiments; the nature of the arm forbids its union in large masses. The same is the case with sappers and miners, they being besides but a very small portion of the army. The French alone make an exception in this latter case. With the regiment the formation of most armies in time of peace is generally considered complete. The larger bodies, brigades, divisions, and army corps, are mostly formed when war breaks out. The Russians and Prussians alone have their army fully organized and the higher commands filled up, as if for actual war.—In war, several battalions or squadrons are formed into a brigade, consisting of from four to eight battalions for infantry, or from six to twenty squadrons for cavalry. With large cavalry regiments these latter may very well stand in lieu of brigade; but they are very generally reduced to smaller strength by the detachments they have to send to the divisions. Light and line infantry may with advantage be mixed in a brigade, but not light and heavy cavalry. The Austrians very generally add a battery to each brigade. A combination of brigades forms the division. In most armies it is composed of all the three arms, say two brigades of infantry, four to six squadrons, and one to three batteries. The French and Russians have no cavalry to their divisions; the English form them of infantry exclusively. Unless, therefore, these nations wish to fight at a disadvantage, they are obliged to attach cavalry and artillery respectively to the divisions whenever the case occurs, which is easily overlooked or often inconvenient or impossible. The proportion of divisionary cavalry, however, is everywhere but small, and therefore the remainder of this arm is formed into cavalry divisions of two brigades each, for the purpose of reserve cavalry. Two or three divisions, sometimes four, are for larger armies formed into an army corps. Such a corps has everywhere its own cavalry and artillery, even where the divisions have none; and where these latter are mixed bodies, there is still a reserve of cavalry and artillery placed at the disposal of the commander of the corps. It has been found

best in the United States to separate the cavalry from the infantry entirely, and form it into separate corps under separate commanders. Napoleon was the first to attach cavalry to his other corps, and, not satisfied therewith, he organized the whole of the remaining cavalry into reserve cavalry corps of two or five divisions of cavalry with horse artillery attached. The Russians have retained this formation of their reserve cavalry, and the other armies are likely to take it up again in a war of importance, though the effect obtained has never yet been in proportion to the immense mass of horsemen thus concentrated on one point, except in America, as heretofore stated.—Such is the modern organization of the fighting part of an army. But, in spite of the abolition of tents, magazines, field bakeries, and bread wagons, there is still a large train of non-combatants and of vehicles necessary to insure the efficiency of the army in a campaign. To enable the commanders of armies, army corps, and divisions to conduct, each in his sphere, the troops intrusted to them, a separate corps is formed in every army except the British, composed of officers exclusively, and called the staff. The functions of these officers are to reconnoitre and sketch the ground on which the army moves or may move; to assist in making out plans for operations, and to arrange them in detail, so that no time is lost, no confusion arises, no useless fatigue is incurred by the troops. They are therefore in highly important positions, and ought to have a thoroughly finished military education, with a full knowledge of the capabilities of each arm on the march and in battle. They are taken in all countries from the most able subjects, and carefully trained in the highest military schools. The English alone imagine that any subaltern or field officer selected from the army at large is fit for such a position, and the consequence is that their staffs are inferior, and the army is incapable of any but the slowest and simplest manœuvres; while the commander, if at all conscientious, has to do all the staff work himself. A division can seldom have more than one staff officer attached; an army corps has a staff of its own under the direction of a superior or a staff officer; and an army has a full staff, with several generals, under a chief, who in urgent cases gives his orders in the name of the commander. The chief of the staff in the British army has an adjutant general and a quartermaster general under his orders; in other armies the adjutant general is at the same time chief of the staff; in France the chief of the staff unites both capacities in himself, and has a different department for each under his orders. The adjutant general is the chief of the *personnel* of the army, receives the reports of all subordinate departments and bodies of the army, and arranges all matters relative to discipline, instruction, formation, equipment, armament, &c. All subordinates correspond through him with the commander-in-chief. If chief of the staff at the

same time, he coöperates with the commander in the formation and working out of plans of operation and movements for the army. The proper arrangement of these in European armies is left to the quartermaster general; the details of marches, cantonments, and encampments are prepared by him. A sufficient number of staff officers are attached to headquarters for reconnoitring the ground, preparing projects as to the defence or attack of positions, &c. There are also a commander-in-chief of the artillery and a superior engineer officer for their respective departments, a few deputies to represent the chief of the staff on particular points of the battlefield, and a number of orderly officers and orderlies to carry orders and despatches. To the headquarters are further attached the chief of the commissariat with his clerks, the paymaster of the army, the chief of the medical department, and the judge advocate or director of the department of military justice. The staffs of the army corps and divisions are regulated on the same model, but with greater simplicity and a reduced *personnel*; the staffs of brigades and regiments are still less numerous, and the staff of a battalion may consist merely of the commander, his adjutant, an officer as paymaster, a sergeant as clerk, and a drummer or bugleman.—To regulate and keep up the military force of a great nation, numerous establishments besides those hitherto named are required. There are recruiting and remounting commissioners, the latter often connected with the administration of national establishments for the breeding of horses, military schools for officers and non-commissioned officers, model battalions, squadrons, and batteries, normal riding schools, and schools for veterinary surgeons. There are in most countries national founderies and manufactories for small arms and gunpowder; there are the various barracks, arsenals, stores, the fortresses with their equipments, and the staff of officers commanding them; finally, there are the commissariat and general staff of the army, which, for the whole of the armed force, are even more numerous and have more extensive duties to perform than the staff and commissariat of a single active army. The staff especially has very important duties. It is generally divided into a historical section (collecting materials relative to the history of war, the formation of armies, &c., past and present), a topographical section (intrusted with the collection of maps and the trigonometrical survey of the whole country), a statistical section, &c. At the head of all these establishments, as well as of the army, stands the ministry of war, organized differently in different countries, but comprising, as must appear from the preceding observations, an immense variety of subjects. Such is the vast machinery devoted to recruiting, remounting, feeding, directing, and always reproducing a modern first-class army. The masses brought together correspond to such an organization. Napoleon's grand army of 1812,

when he had 200,000 men in Spain, 200,000 in France, Italy, Germany, and Poland, and invaded Russia with 450,000 men and 1,300 guns, was equalled in 1870, when Prussia put almost her entire armed force in the field against France, under the immediate command of King William, assisted by Gen. Von Moltke and an able assemblage of army and corps commanders. This remarkable campaign, although it was characterized by no extraordinary loss of life either to the French or the Prussians, resulted in the capture or annihilation of the entire French army and the complete prostration of the French empire. The Prussian army engaged in the campaign earned for itself the reputation of being the most perfect, all things considered, in the world. Its artillery and infantry are specially good, but its cavalry seems to be behind the age.—The military system of the United States is based upon volunteer armies raised as occasion demands. During the civil war, from first to last, 2,690,401 men (including reenlistments) were enrolled, equipped, and organized into armies. The principal of these were the army of the Potomac, the army of the Tennessee, the army of the Cumberland, and the army of the Ohio; the last three were finally united into one command, known as the military division of the Mississippi. The troops constituting these armies were raised by the various loyal states, by regiments, under proclamation and demand from the president of the United States, the numbers being apportioned by the secretary of war, through the provost marshal general, according to the population of the respective states. As soon as the various regiments were mustered into the service of the United States, they were under the complete control of the general government, and were afterward assigned to brigades, divisions, corps, and armies, according to the requirements of the service, and generally without regard to the states from which they came. They received their pay, arms, clothing, and subsistence from the United States, though, with a few exceptions, as in the case of the colored troops, the field and line officers received their commissions and promotions from the governors of their respective states. All general and general staff officers were commissioned by the president, and no officer after having been mustered into the service of the United States could be dismissed by the state authorities. The requisitions upon the various states were generally filled with a reasonable degree of promptitude, although, owing to the great expansion of the currency due to the emission of paper money and the great stimulation of the various industries of the country engaged in the production of army supplies, the rates of wages advanced so rapidly that before the war ended it became exceedingly difficult to raise volunteers, except by the payment of bounties amounting in many instances to \$1,500 per man. The use of this system resulted in the success of the national arms, but

at an extravagant cost in men, material, and money. Immediately after the termination of the war the volunteer army, amounting to about 1,100,000 men, was quietly and rapidly disbanded, the various regiments returning to their respective states, and becoming at once absorbed in the body of the people, without the slightest disturbance of the peace and order of society, or derangement of its industries. The regular army, which during the war had been increased from about 18,000 men to something over 50,000, was reduced by successive steps to 30,000 men. This force is mainly used for garrisoning the permanent fortifications, for protecting the highways across the continent, and preserving order among the Indian tribes of the west.

ARNAULD, a French family, several members of which are noted in connection with the convent of Port Royal and the Jansenist controversy. **I. Antoine**, born in Paris in 1560, died there, Dec. 29, 1619. He was an advocate, and gained celebrity by an argument in 1594 against the Jesuits, and in favor of the university of Paris. He was the author of *Arts au roi Louis XIII. pour bien régner*, and of various other writings. He was a Roman Catholic, although denounced by the Jesuits as a Huguenot. He was the father of 20 children, ten of whom died young, and the others, four sons and six daughters, became connected with the Port Royal convent. **II. Robert Arnauld d'Andilly**, eldest son of the preceding, born in Paris about 1588, died at Port Royal, Sept. 27, 1674. He was originally an advocate, and like his father distinguished himself by a plea for the university of Paris and against the Jesuits. At the age of 55 he retired to a farm adjoining the convent of Port Royal, where he passed the remainder of his life in seclusion, devoting his time to theological subjects, and writing and translating. Among his works are translations of the "Confessions" of Augustine and of Josephus's "History of the Jews," memoirs of his own life, *La vie de Jésus* (a poem), and *Vies des saints pères du désert et de quelques saintes* (3 vols. 8vo), which he considered his best work. **III. Henri**, bishop of Angers, brother of the preceding, born in Paris in 1597, died at Angers about 1692. He was destined for the bar, but on receiving from the crown the gift of the abbey of St. Nicholas, entered the church. He was elected bishop of Toul by the diocesan chapter, but, some question arising, he refused to accept the position. In 1645 he went to Rome to appease the quarrel between the Barberini family and Pope Innocent X.: in this he was so successful that a medal was struck and a statue erected in his honor. Returning to France, he was in 1649 made bishop of Angers. He became a zealous Jansenist, and was one of the four bishops who refused to sign the acceptance of the papal bull condemning the *Augustinus* of Jansenius. He was accustomed to take only five hours' sleep, that he might gain time for prayer and reading the

Scriptures. He left his diocese only on one occasion, and that was to reconcile the prince of Tarento to his father, the duke de la Trémoille. In 1652 Angers revolted, and the queen mother was about to take heavy vengeance, but was prevented by Arnauld, who in administering the sacrament said to her, "Take the body of Him who forgave his enemies when on the cross." He was urged to take one day in the week for recreation; but replied, "I will do so when you find me a day when I am not a bishop." His *Négociations à la cour de Rome* (5 vols., 1748) contain many curious facts and anecdotes. **IV. Antoine**, called "the great Arnauld," youngest son of Antoine, and brother of the two preceding, born in Paris, Feb. 6, 1612, died near Liège, Aug. 8, 1694. He studied for the law, but was induced to turn his attention to theology. In 1641 he became a priest, and was made doctor of the Sorbonne. In 1643 he was made associate of the Sorbonne. In this year he published his famous work *De la fréquente communion*, which was sharply attacked by the Jesuits. Arnauld replied in his *Théologie morale des Jésuites*, which was the beginning of a long and fierce controversy. His opponents endeavored to have him summoned to Rome, to avoid which he retired to the convent of Port Royal des Champs, near Paris. Soon afterward he became involved in the disputes concerning Jansenius and his *Augustinus*, several propositions in which had been (Aug. 1, 1641) condemned by Pope Urban VIII. Arnauld undertook to defend the work of Jansenius against the papal bull. Besides strictly controversial works, he wrote at this period *Mœurs de l'église catholique*; *La correction*; *La grâce*; *La vérité de la religion*; *De la foi, de l'espérance et de la charité*; and the *Manuel de Saint Augustin*; and translated his *Fréquente communion* into Latin. He also undertook the spiritual direction of the nuns in the convent of Port Royal, of which his sister Marie Jacqueline was abbess. In connection with Pascal, Nicole, and others, he prepared several elementary works on education. "The Port Royal Grammars" held their place as text books for a long time. In 1649 the Jansenist controversy broke out afresh, and the *Augustinus* was again condemned by the pope. In 1655 or 1656 Arnauld found it necessary to leave Port Royal and seek a secret place of refuge; he was at this time expelled from the Sorbonne, and from the faculty of theology, 72 doctors and many licentiates going out with him. For Pascal's famous "Provincial Letters," against the Jesuits, Arnauld furnished the materials, the wit and satire being Pascal's. In 1658 Arnauld entered personally into the contest, in his *Cinq écrits en faveur des curés de Paris contre les casuistes relâchés*, which was followed in 1662 by *La nouvelle hérésie*, and in 1669 by the first volume of his *Morale pratique*, the last volume of which was not published until the year of his death. All

these works were directed against the Jesuits. The peace of Clement IX. (1668) for a time allayed the Jansenist controversy. Arnauld contributed to this by an eloquent memorial to the pontiff. He was presented to the papal nuncio, and to Louis XIV., who received him graciously, and urged him to "employ his golden pen in defence of religion." Arnauld, in conjunction with Nicole, wrote a work *De la perpétuité de la foi de l'église catholique*, which was dedicated to the pope. This work gave rise to a controversy between Arnauld and the reformed minister Claude. The bishop of Paris procured from Louis XIV. an order for the arrest of Arnauld, who concealed himself for a time in the house of the duchess de Longueville; but in 1679 he went to Brussels, where he was assured of protection. Here in 1681 he published his *Apologie pour les Catholiques*, a defence of his old antagonists the Jesuits against the absurd charges brought forward in England by Titus Oates. In 1689 appeared an anonymous work, afterward shown to be written by Arnauld, directed against the prince of Orange, William III. of England, in which that statesman was designated as "a new Absalom, a new Herod, and a new Cromwell." In opposition to the views of his old friend Malebranche, Arnauld wrote in 1683 his *Traité des vraies et des fausses idées*, and in 1685 his *Réflexions philosophiques et théologiques sur le nouveau système de la nature et de la grâce du père Malebranche*. He continued to the last, even when more than 80 years old, to carry on his controversies with Malebranche, with the Calvinists, and with Bayle and other sceptical philosophers. His last work, *Réflexions sur l'éloquence des prédicateurs*, appeared in 1694. His writings, as named by Moréri, comprise 320 works; and as originally published they appeared in 100 volumes. They were collected and published at Lausanne and Paris in 45 vols. 4to (1775-'83). **V. Marie Jacqueline Angélique**, abbess of Port Royal, sister of the preceding, born in 1591, died Aug. 6, 1661. At the age of 14 she was made abbess of Port Royal des Champs. At 17 she was directed by the general of the order of St. Bernard to reform the abbey of Maubuisson, where she subjected herself to all the privations imposed upon the sisterhood. She became convinced that her election as abbess of Port Royal was invalid, and resigned, after having secured a provision that thereafter the abbesses should be chosen triennially. Some years afterward the pope chose her to establish a new convent which the duchess de Longueville was about to found in honor of the holy sacrament. This establishment not continuing, Marie Jacqueline returned to the convent of Port Royal, and was again elected abbess, a position which she retained for 12 years. Racine, in his *Histoire de Port Royal*, attributes to her the authorship of the history of the persecution suffered by the nuns, which was published at Paris in 1724. **VI. Agnes**, sister of the preceding, born in 1594, died

Feb. 19, 1671. She entered the convent when a mere child, and at the age of 15 was appointed mistress of the novices. She was at the head of the establishment during the five years which her sister passed at Maubuisson; then became her coadjutor, and was subsequently chosen abbess, and for 27 years governed Port Royal, alternately with her sister, whom she survived nine years. She was the author of two books, *Le chaplet secret du Saint Sacrement* (1663), which was suppressed at Rome, but without being formally censured, and *L'image de la religieuse parfaite et imparfaite* (1665). The *Constitutions de Port Royal* are also attributed to her. These abbesses were two of six sisters, all belonging to one convent, and all attached to the Jansenist party. The archbishop of Paris said that they were "as pure as angels, but as proud as devils." VII. *Angélique*, usually designated by her conventual name Mère Angélique de St. Jean, born in Paris, Nov. 24, 1624, died there, Jan. 29, 1684. She was the daughter of Robert Arnauld d'Andilly, and niece of the four preceding. She was educated in the convent of Port Royal by her aunt Marie Jacqueline. When not quite 20 years old she became a nun, and nine years afterward was chosen sub-prioress of the convent. When the establishment was removed to Port Royal de Paris she retained the same position. A royal order having been issued for breaking up the institution, the inmates were arrested by the police, and dispersed through various convents, every endeavor being made to induce them to accede to the formulary of Pope Alexander VI. From these solicitations Angélique was especially excepted, because her "known obstinacy" made it sure that she would not agree. At length the nuns were restored to Port Royal des Champs, but were for years subjected to the surveillance of the police, no intercourse being permitted between them and persons outside of the convent. In 1669 the Port Royal society was reconstituted, Angélique being again elected prioress. In 1688 she was chosen abbess. But the next year her powerful protector, the duchess de Longueville, died, and the persecution was renewed, it being expressly ordered that no new novices should be admitted. Angélique exerted herself to stem the storm; she consoled the nuns, and put forth all her influence with persons in power. Her efforts were unavailing, and she sank under a complication of griefs. She was learned, pious, and gentle. She wrote several books, the most valuable of which is *Mémoires pour servir à l'histoire de Port Royal, et à la vie de la révérende Mère Marie Angélique de Sainte Madeleine Arnauld, réformatrice de ce monastère* (3 vols., Utrecht, 1742). She also took a considerable part in the preparation of the *Nécrologie de Port Royal des Champs* (Amsterdam, 1723), and wrote other works in defence of the convent.

ARNAULT, Vincent Antoine, a French author, born in Paris in January, 1766, died near Havre,

Sept. 16, 1834. He became first known to fame by two tragedies, *Marius à Minturnes* and *Lucrèce*. After the massacres of September, 1792, he went to London and Brussels, and on his return in 1793 was arrested, but soon set free. In 1797 Bonaparte sent him on a mission to the Ionian Islands. In 1799 he produced in Paris a tragedy, *Les Vénitiens*, suggested by his residence at Venice, which was very favorably received by Napoleon himself, before whom he delivered several lectures on that city. He became in the same year member of the French academy, in 1805 vice president and in 1808 principal secretary of the council of the university. All these offices were taken from him after the emperor's downfall, but restored to him during the hundred days. Besides his tragedies he wrote a number of miscellaneous prose works and poems, a collection of fables, and *Vie politique et militaire de Napoléon* (3 vols. fol., Paris, 1822), and prepared with Jay, Jouy, and De Norvins the *Nouvelle biographie des contemporains* (20 vols. 8vo, 1820-'25).

ARNAUTS. See ALBANIA.

ARND, or Arndt, Johann, a German theologian, born at Ballenstedt, Anhalt, Dec. 27, 1535, died at Celle, May 11, 1621. He was pastor successively at Paderborn and Quedlinburg, and in 1599 was appointed preacher to the court at Brunswick. In 1611 he was presented by the duke of Lüneburg to the church at Celle, and he soon afterward became superintendent of all the churches of the duchy, which office he held till his death. His writings are marked by great fervor of devotion. His principal work, on "True Christianity," which has been translated into almost all European languages, approaches so near to mysticism that it was attacked during the lifetime of its author as a dangerous and heretical production. The fact that he gave liberally to the poor, while himself in poverty, gave rise to a belief that he had discovered the secret of making gold.

ARNDT, Ernst Moritz, a German patriot, professor of history at the university of Bonn, born at Schoritz, on the island of Rügen, Dec. 26, 1769, died in Bonn, Jan. 29, 1860. He studied at Greifswald and Jena, and after travelling over Europe was appointed professor at Greifswald, where he soon published his "History of Serfdom in Pomerania and Rügen," which roused the wrath of some members of the Pomeranian nobility. In 1807 appeared the first volume of his *Geist der Zeit*, containing his attack against Napoleon, for which he was expelled from the country. He then went to Stockholm, where, under a feigned name, he supported himself by teaching languages. In 1810 he ventured to return to Greifswald in disguise, but on hearing of the Russian campaign, he proceeded in 1812 to St. Petersburg, and published pamphlet after pamphlet to rouse the public mind of Europe from its lethargy. His cry was, If Napoleon is successful in Russia, Germany is undone. Baron Stein

sympathized and acted with him. At this time he wrote his book defining the Rhine as a German river, and also his stirring national songs, including *Was ist des Deutschen Vaterland?* In 1818 he became professor of modern history at Bonn, but his liberal ideas soon gave renewed offence at Potsdam. He was tried for treason, and though no verdict could be found against him, it was 20 years before the king would allow him to teach history again. In 1848 he was sent as deputy to the Frankfort parliament; but on May 21, 1849, he withdrew from parliament with the whole constitutional party, which was in favor of a hereditary empire. He returned to Bonn, where, constantly employed in literary labor, he passed an active and happy old age, known and honored throughout Germany, under the popular name of "Father Arndt," as one of the foremost liberators of the country from foreign tyranny and home abuses. A monument in his honor was placed on a plateau near Bonn, July 29, 1865. His residence and garden have been purchased and presented to the city of Bonn.

ARNE, Thomas Augustine, an English composer of music, born in London in 1710, died March 5, 1778. His father, an upholsterer, gave him a good education at Eton, and bound him apprentice to an attorney, but afterward consented to his following his inclination and devoting himself exclusively to musical composition. In 1733 he set to music Addison's "Rosamond" and Fielding's "Tom Thumb," under the name of the "Opera of Operas," both of which were received with much favor. The former was composed chiefly for his sister, afterward the celebrated Mrs. Cibber. In 1738 he wrote the music to Milton's "Comus," which firmly established his reputation as a composer. During the next 20 years he wrote operas for Drury Lane theatre, oratorios, and a vast number of songs. In 1762 his most famous work, "Artaxerxes," an opera after the Italian style, was produced, and for many years held a prominent place on the lyric stage. His other most successful works were the "Judgment of Paris," "Eliza," "Britannia," a musical farce entitled "Thomas and Sally," "The Fairies," and "The Stratford Jubilee." His oratorios, owing to the competition of Handel's works, were comparative failures. As a composer of songs Dr. Arne was unsurpassed by any English writer since the time of Purcell; and many of them, such as "Rule Britannia," and "The Soldier Tired," are still popular. In 1769 he received from Oxford the degree of doctor in music.

ARNHEM, or **Arnhem** (anc. *Arnenacum*), a city of Holland, capital of the province of Gelderland, on the right bank of the Rhine, 30 m. E. by S. of Utrecht; pop. in 1871, 33,181, half Roman Catholics, and the rest mostly Protestants. It was once a strong fortress, but the ramparts have been converted into promenades, and the fine situation has made the adjoining pleasure grounds and villages favorite resorts of distinguished and opulent persons,

including many retired East India merchants. The town hall is called the Devil's House, from the peculiar adornments of its front. In the church of St. Eusebius (the *Groote Kerk*) are the tombs of the dukes and counts of Gelderland and a fine mausoleum of one of the former, Charles of Egmont. The pulpit of the St. Walburg Roman Catholic church was designed by Cuypers. There are many other interesting public buildings, including the Bronbeek, a hospital for East India invalid soldiers, various educational and literary institutions, and a renowned music hall (*Musis sacrum*). The trade, much increased by railway communications, consists in the export of cereals and tobacco, and in a large commission business with Germany. Carriages, mirrors, turnery, and mathematical and other instruments are manufactured. In the middle ages it was called Arnoldi Villa. Sir Philip Sidney died here in 1586. In 1813 it was stormed by the Prussians.

ARNICA, a genus of plants of the natural order *compositæ*. The *arnica montana* or leopard's bane grows in the mountainous districts of the north and middle of Europe, blossoming in June and July. Its flowers, leaves, and root are employed in medicine, but the flowers are usually preferred. A tincture and extract are prepared from the flowers, and a tincture from the root. An infusion may be used. Arnica contains a volatile oil, bitter extractive, and resin, the first being probably the active constituent. When

Arnica montana.

taken internally arnica produces increased rapidity of the pulse, headache, dizziness, and spasmodic twitchings of the muscles, with occasional vomiting and diarrhoea. Externally it is a slight irritant. It has been used, more in Germany than in this country, in low forms of fever and nervous diseases. It is largely used as a remedy for sprains and bruises.

ARNIM, or **Arnheim**, **Johann Georg**, a German soldier, born at Boitzenburg in 1581, died in Dresden, April 18, 1641. He fought under Gustavus Adolphus against Russia, and in the Polish service against the Turks, and was a favorite officer of Wallenstein, who made him field marshal. In 1631 he joined the elector of Saxony, commanded the Saxon troops at Breitenfeld, invaded Bohemia, took Prague, and was victorious at Nimburg, in 1632 returned to Saxony, then fought in Brandenburg and Silesia, and in 1634 defeated the imperialists at Liegnitz. In the following year he left

the service, and in 1637 was arrested by the Swedes on account of an alleged former secret understanding with Wallenstein. In November, 1638, he escaped from Stockholm to Hamburg, and raised at his own expense and with the consent of the imperial and Saxon authorities an army of 16,000 men against Sweden, but died before he could engage in active operations.

ARNIM, Karl Otto Ludwig von, a German author, born in Berlin, Aug. 1, 1779, died there, Feb. 9, 1861. His books of travel in France, Italy, Spain, Russia, and the East (Berlin, 6 vols., 1838-'50) are much valued.

ARNIM, I. Ludwig Achim (Joachim) von, a German poet, one of the leaders of the "romantic school" in German literature, born in Berlin, Jan. 26, 1781, died at his estate Wiepersdorf, near Dahme, Jan. 21, 1831. He devoted himself in his youth to scientific studies, but even in these his researches were of a fantastic nature, and showed the tendency of his mind, which soon exhibited much of its singular originality in the earliest of his literary works, *Ariel's Offenbarungen* (Göttingen, 1804). Soon after the publication of this book he travelled in Germany, studying the habits of the common people, and tracing to their sources the current folk songs and legends. Of the almost forgotten beauties found among these popular ballads and tales he made excellent use in several of his works which appeared soon after—the principal portions of *Des Knaben Wunderhorn* (3 vols., Heidelberg, 1806-'8; 2d ed., 1819); *Wintergarten, eine Sammlung von Noellen* (Berlin, 1809); *Armut, Reichthum, Schuld und Busse der Gräfin Dolores* (2 vols., Berlin, 1810); *Halle und Jerusalem, Studentenspiel und Pilgerabenteuer* (Heidelberg, 1811); and the *Schaubühne* (Berlin, 1813). In 1811 he married Elisabeth Brentano, afterward celebrated as Bettina von Arnim. During the years of Napoleon's rule in Germany, Von Arnim was among the patriots who strove most energetically to arouse his countrymen against the conqueror's despotism. The years of the war brought financial trouble upon him, and he wrote but little for a considerable time. That difficulty over, he again appeared in literature and published several works, of which *Die Kronenwächter, oder Berthold's erstes und zweites Leben*, was the chief. His complete works were published by Grimm, in 19 volumes (Berlin, 1839-'46). **II. Elisabeth von**, best known as BERTINA, wife of the preceding, and sister of the poet Clemens Brentano, born in Frankfurt-on-the-Main, April 4, 1785, died in Berlin, Jan. 20, 1859. Her education was little guided by her friends, and its entire freedom from conventional rules probably exaggerated the eccentricities which she began at an early age to display. A part of her youth was spent in a convent, a part in Offenbach and Marburg, but Frankfurt was her favorite home. She formed a friendship with a canoness, Fräulein Günderröde, who exerted over her naturally fantastic

habits of thought a most unhealthy influence; the two friends acknowledged only a singularly fanciful worship of nature, and natural impulses, laws, and methods of life; a dreamy brooding over this and the "tyranny" of conventionalities soon grew into almost a mental disease. Fräulein Günderröde committed suicide on account of an unhappy passion for the philologist Creuzer, and this event still further affected Bettina's morbid current of thought. Soon after her friend's death she entered into correspondence with Goethe, for whom she contracted a fantastic love. The poet, now nearly 60 years of age, treated this as a child's whim, and, without encouraging, still did not repel it, though he in no way returned her feeling. The outgrowth of their singular correspondence was Bettina von Arnim's book *Goethe's Briefwechsel mit einem Kinde* (3 vols., Berlin, 1835), a record since proved to be so full of falsifications, distortions, and affectations as to be worth little save as a record of its author's egotism and eccentricity. (See Lewes's "Life of Goethe.") She herself translated the work into English. After her marriage to Achim von Arnim in 1811, she lived in Berlin, where her mind took a healthier tone from her active charity and from the absence of her former surroundings. In 1840 portions of her correspondence with her old friend the canoness were published under the title *Die Günderröde* (partly translated into English by Margaret Fuller). Her house was a well known rendezvous of the most famous literary characters of the day, among whom she was known only as "Bettina" even in her old age. Her noteworthy works besides those mentioned above were: *Dies Buch gehört dem Könige* (2 vols., Berlin, 1843); *Hiuss Pamphilus und die Ambrosia* (2 vols., 1848); *Gespräche mit Dämonen* (1852). In analyzing Bettina's character, it is difficult to determine how much of her eccentricity is attributable to her actual peculiarities, and how much to a morbid egotism and affectation, largely influenced by the opinions of the unsettled and disorganized time in which she lived. **III. Gisela von**, daughter of the preceding, and wife of Hermann Grimm, has become known as a writer by her *Dramatische Werke*, published two years before her mother's death (2 vols., Bonn, 1857).

ARNO, a river of Tuscany, rises on the S. slope of Monte Falterona in the Apennines, 6 m. N. of Prato Vecchio, flows S. to the neighborhood of Arezzo, where it is joined by the Chianassa and the Chiana, thence N. W. to Pontassieve, where it receives the Sieve, thence follows a westerly course through Florence and Pisa to 7 m. below the latter city, where it flows into the Mediterranean through a channel cut for it in 1603; length 150 m. It is navigable for small vessels from the sea to Florence, but further is liable to be obstructed by floods and droughts. To guard against the former, it has been embanked for the greater part of its course. The valley

through which the Arno flows between Florence and Pisa is the very garden of Italy, and is famous for its beauty.

ARNOBIUS, an African rhetorician, born in Sicea Veneria (supposed to be the Tunisian Keff), on the eastern border of Numidia, flourished at the beginning of the 4th century. He was a violent opponent of Christianity, which had been introduced into Numidia as early as 250, until, tradition says, he was warned in a dream to embrace the new religion. There is, however, reason to ascribe his conversion to a rational investigation of the gospels. On his conversion he applied to the bishop of Sicea for admission to the church. The bishop desired some-proof of the sincerity of a man who had been so zealous a defender of paganism. Arnobius therefore wrote the famous treatise entitled *Adversus Gentes*, in which he gives proof of his zeal for Christianity by exposing the fallacies of his former faith. The *Adversus Gentes* inclines to Gnosticism and Dualism, in the conclusion that, since the Supreme Being would not have created so imperfect a work as the human soul, it must have been created by some inferior being in his image. Arnobius taught that immortality was not an attribute of the soul, but could only be acquired by effort to conquer evil and rise to the supremacy of good.

ARNOLD, Benedict, an officer in the American revolutionary army, born in Norwich, Conn., Jan. 3, 1740, died in London, June 14, 1801. He was trained to mercantile pursuits, but, being of a restless and reckless disposition, was invariably unsuccessful in trade. He showed, however, considerable aptitude for military life, and at the outbreak of the American revolution was the captain of a company of Connecticut militia known as the "governor's guards." At the head of this command he repaired to Cambridge, Mass., after the battle of Lexington, and was commissioned a colonel. He cooperated with Ethan Allen in the capture of Forts Ticonderoga and Crown Point on Lake Champlain, and in the latter part of 1775 was appointed, in connection with Gen. Richard Montgomery, to the command of an expedition against Canada, whence with Montgomery he made (Dec. 31) a gallant but unsuccessful assault upon Quebec, receiving a severe wound in the leg. For these services he was rewarded by congress with the commission of a brigadier general. He remained on the northern frontier during the ensuing spring and summer, and, having organized a flotilla on Lake Champlain, fought a desperate battle on Oct. 11, 1776, with a greatly superior British force, in which he was worsted. On the succeeding day he ran his vessels on shore and fired them, and then retired unmolested to Ticonderoga. Notwithstanding these exploits, he was omitted from the list of five major generals who soon after were appointed by congress. A letter from Washington soothed his wounded vanity, but there is little doubt that the injustice of

congress in this instance first suggested to his mind the idea of betraying his country. Receiving permission to visit Philadelphia, where congress was then sitting, he took part near Danbury, Conn., in an encounter with a superior body of British troops, and again distinguished himself by coolness and audacity in the presence of extreme danger. Congress finally commissioned him a major general, but still left him below the five others recently appointed, which only intensified his feelings of resentment. In the summer of 1777 he joined the northern army under Gates, and by a brilliant movement relieved Fort Stanwix, on the Mohawk, besieged by a large force of British and Indians. He was prevented by the jealousy of Gates from taking an active part in the first battle of Bemis Heights, but in the second battle, Oct. 7, he entered the field without permission, led the last desperate charge against the Hessian encampment, and was severely wounded in the leg as he rode into the sallyport. Having partially recovered from his wound, he was appointed in June, 1778, to the command of Philadelphia, then recently evacuated by the enemy. During the nine months that he occupied this position he governed with a high hand, and the council of Pennsylvania preferred charges of misconduct, for which he was tried by a court martial, and in January, 1780, was sentenced to be reprimanded by the commander-in-chief, who performed the unwelcome duty in as lenient a spirit as possible. Although in presenting his case to the court he had announced in exalted terms his devotion to the American cause, it was subsequently discovered that for many months previous he had been in secret and treasonable correspondence with the enemy. His marriage while in Philadelphia with Miss Shippen, a lady of strong tory predilections, also predisposed him to look favorably upon any scheme of betrayal of his country. In this frame of mind he solicited and received the command of the works at West Point, alleging that his wounds still precluded him from active service in the field. He entered upon his new duties on Aug. 3, 1780, and established his headquarters at a house on the opposite bank, which had formerly belonged to Col. Beverly Robinson of Virginia, a tory. He had now been nearly 18 months in treasonable correspondence with Sir Henry Clinton, the British commander-in-chief at New York, and his immediate object was the surrender to him of West Point, then considered the key of communication between the eastern and southern states. The correspondence was conducted on the part of Clinton by his adjutant general, Major André, who used the pseudonyme of "John Anderson," while Arnold signed himself "Gustavus." In September, 1780, the plot being ripe, Arnold requested a personal interview with André at headquarters to settle the final details. On the 18th, the very day when this meeting should have taken place, the

arrival of Washington and his suite at Verplanck's Point, on his way to Hartford to meet the French admiral Rochambeau, greatly embarrassed Arnold; but with characteristic audacity he showed him a portion of the treasonable correspondence having reference to the proposed conference, but which was so artfully worded as to disarm suspicion. Washington strongly advised Arnold to hold no meeting with persons coming from within the enemy's lines, as such an act, taken in connection with the recent court martial, might injure him in public estimation. On the night of the 21st the meeting with André, who had disembarked from the British frigate *Vulture*, finally took place at the foot of Clove mountain, a few miles below Stony Point. It was continued into the morning of the 22d, when, having given André a safe-conduct to pass him through the American lines, and six papers disclosing the plans of the works at West Point and the strength of the garrison, Arnold returned to his headquarters. The *Vulture* having meanwhile dropped down stream in consequence of a fire from the American batteries, André was obliged to return to New York along the eastern bank of the Hudson, and on the 23d was captured near Tarrytown. The papers found on his person were at once despatched to Washington at Hartford; but Col. Jameson, the officer in whose charge he was placed, committed the error of informing Arnold of the circumstance. After a hurried parting with his wife, Arnold was rowed in his barge to the *Vulture*, where he then basely delivered the oarsmen to the enemy; but Sir Henry Clinton at once ordered them to be released. On the same day the papers found on André's person were examined by Washington, and the whole treasonable scheme was exposed, just in time probably to defeat the most formidable plan ever organized to crush the cause of American liberty. Arnold was rewarded for his treachery by a commission as major general in the British army, and took part in several marauding expeditions into Connecticut and Virginia. After the surrender of Cornwallis he went to England and received a considerable sum in money from the British government. His subsequent life was neither prosperous nor happy. He was shunned by men of honor and repeatedly insulted. After several unsuccessful attempts to engage in business in British America and the West Indies, he sank into utter obscurity.—**JAMES ROBERTSON**, second son of the preceding, born in the United States in 1780, died in London, Dec. 27, 1834. He entered the British army in 1798, and served with credit in many parts of the world. For several years he was an aide-de-camp of William IV. Three years before his death he was promoted to be a lieutenant general.

ARNOLD OF BRESCIA (ARNALDO DA BRESCIA), a religious reformer, born at Brescia in Italy about the beginning of the 12th century, executed at Rome in 1155. He first ap-

pears in history as a scholar of Abélard, and was distinguished for eloquence. Returning from France to Italy, he attacked the luxury, venality, indifference to religious duties, and degrading worldliness of the clergy. His special doctrine was the antagonism of the church to the world. He held that the same man ought not to hold secular and religious office. This doctrine speedily made for him a party. Disturbances broke out, the clergy protested, the bishop of Brescia became alarmed, a complaint was sent to Rome, and at the council of the Lateran in 1139 Arnold was condemned as a disturber of the peace, forbidden to preach, and banished from Italy. His party, however, was not annihilated, nor his influence destroyed. In France, where he went to visit Abélard, whose name had been joined with his in the sentence of condemnation, and in Switzerland, where he preached for some years, he gained many adherents. Meanwhile, a bold application of his principles had been attempted in Rome itself. The demands of the papal see excited a popular movement (1143), and secular authorities were appointed to govern the state, while the pope, Innocent II., was restricted to the exercise of spiritual authority. This change in the national government being opposed by Innocent and his successors, a revolt broke out in 1145, and Pope Eugenius III. was forced to leave the city. Arnold went to Rome and assumed the direction of the popular movement; but the license of rioters hindered his plans, reaction came, one by one his reforms were nullified, and the unfortunate murder of a cardinal in the street enabled Pope Adrian IV. to turn against this alleged disturber of the peace and enemy of the church the sympathies of the populace. Arnold was with his friends driven from the city, and sought refuge with some noblemen of Campania. When the emperor Frederick Barbarossa came to Rome to be crowned, the pope asked him to have Arnold arrested. The order was given and executed, and Arnold was strangled, and his body burned and thrown into the Tiber.—The character of Arnold has been variously represented. Baronius calls him "the father of political heresies." The truth appears to be that he was a great reforming spirit, who fell into many errors and excesses, but whose leading idea was to renovate the clerical order after the apostolic model. Baptist writers claim him as one of the forerunners of their faith, the denial of infant baptism being among the charges against him at the Lateran council of 1139. A sect called Arnoldists existed in Italy for some time after his death. They were condemned at the council of Verona in 1184, and the name occurs in a law against heretics of Frederick II. (1224).

ARNOLD, Christoph, a German astronomer, born at Sommerfeld, near Leipsic, Dec. 17, 1650, died April 15, 1695. He was a farmer, but devoted his leisure to astronomy, erected an observatory at his own house, and was the

first to call attention to the comets of 1682 and 1686. He also acquired fame by his observation of the passage of Mercury across the sun's disk, Oct. 31, 1690. The town of Leipsic gave him a present of money and exempted him from all city taxation.

ARNOLD, Edwin, an English author, born June 10, 1831. In 1852 he obtained at Oxford the Newdegate prize for one of his poems, became in 1854 second master in a principal school of Birmingham, and subsequently was president of the Sanskrit college at Poonah, British India, which office he resigned in 1860. He is a voluminous contributor to daily journals and periodicals, and has published "Poems, Narrative and Lyrical;" "Griselda, a Tragedy, and other Poems" (1856); "The Wreck of the Northern Belle" (1857); "History of the Administration of India under the late Marquis of Dalhousie" (2 vols., 1862-'4); and "Poets of Greece" (1869).

ARNOLD, Matthew, an English poet, son of Thomas Arnold, born at Laleham, Dec. 24, 1822. He was educated at Winchester, Rugby, and Oxford; won the Newdegate prize for English verse by a poem entitled "Cromwell;" in 1845 was chosen fellow of Oriel college; and from 1846 to 1851 was private secretary to Lord Lansdowne. Having married, Mr. Arnold received an appointment as one of the lay inspectors of schools under the committee of the council of education. In 1849 he published anonymously a small volume of poems under the title of "The Strayed Reveller and other Poems." In 1852 a second volume appeared, "Empedocles on Ætna, and other Poems." In 1853 a new volume was issued in his own name, followed by a second series, the two containing selections from the previous collections along with some fresh pieces. On May 5, 1857, Mr. Arnold was elected professor of poetry in the university of Oxford. His later noteworthy works are: "Balder;" "Merope, a Tragedy" (1858); "On Translating Homer" (1862); "Essays in Criticism" (1865); "Study of Celtic Literature" (1867); "Schools and Universities on the Continent" (1868); "Culture and Anarchy" (1869); "St. Paul and Protestantism" (1870); "Friendship's Garland" (1871); "Literature and Dogma" (1873).

ARNOLD, Samuel, Mus. Doc., an English composer, born in London, Aug. 10, 1740, died there, Oct. 22, 1802. At the age of 23 he became composer to Covent Garden theatre, and in 1766 also to the Haymarket, in 1789 conductor of the academy of ancient music, and in 1793 organist of Westminster abbey. He published 47 operas, of which "The Maid of the Mill" was for many years a favorite on the stage. "The Prodigal Son," an oratorio, also had remarkable success. About 1786 he published a collection of cathedral music (4 vols.), which has always been held in high esteem. He undertook, under the patronage of George III., an edition in score of Handel's works, of which he published 40 volumes.

ARNOLD, Thomas, D. D., an English teacher and historian, born at West Cowes, Isle of Wight, June 13, 1795, died at Rugby, June 12, 1842. When 8 years old he was sent to Warminster, and at 12 to Winchester college, where he was known as an indolent, shy, and restless boy. In 1811, having obtained a scholarship at Corpus Christi, he removed to Oxford, where in 1814 he took a first class degree, and the year after was elected fellow of Oriel college. In 1815 and 1817 he was chancellor's prizeman for the Latin and English essays. In 1818 he was ordained deacon, and from 1819 employed himself at Laleham, near Staines, in the preparation of young men for the universities. From this point his career seems to have fairly commenced. On his application for the post of head master of Rugby school, he was elected, though others had applied before him, the trustees being assured that "he would change the face of education all through the public schools of England." He entered upon the duties of this office in August, 1828, having shortly before taken priest's orders. Dr. Arnold enlarged the basis of education at Rugby by adding to the classics other departments of learning; but his influence was chiefly felt in the practical bearing upon life and character which he gave to all education, and in the lofty Christian spirit which he endeavored to impart to his scholars. He substituted for the old system of fagging a responsible supervision of the younger lads by the boys in the highest class—a plan that was criticised in some quarters, but which he defended in the "Journal of Education" (1834-'5). He was a strenuous opponent of the new school at Oxford. He took part in the debate upon church and state, wrote a pamphlet in 1833 upon "Church Reform," and later "Fragments upon the Church," in which he urged that church and state, instead of being formally united as two separate interests, should rather be identified, the state being in fact the working church. In 1835 he accepted a fellowship in the senate of the new London university, but resigned it three years later on account of the refusal of the senate to make an examination in the New Testament obligatory upon candidates for a degree. He delivered lectures before the Rugby mechanics' institute, and in 1831 started a periodical called the "Englishman's Register," of which only a few numbers were published. He declined political preferment; and when Lord Melbourne appointed him to the regius professorship of modern history at Oxford, he welcomed it as the post of all others best suited to him. He held it but one year, when he suddenly died of heart disease. His "History of Rome," a work of great merit, in 3 vols. (1838, 1840, 1842), embodying the results of Niebuhr's investigations, carried the narrative to the end of the second Punic war; a fourth volume extends the history, in fragments, to the time of Trajan. He also published an edition of Thucydides with notes, a course of lectures on modern history.

five volumes of sermons, and a volume of miscellaneous writings. His correspondence in two volumes was published, with a memoir, by the Rev. A. P. Stanley.

ARNOLD, Thomas Kerchever, an English clergyman and author, born in 1800, died March 9, 1853. He was educated at Trinity college, Cambridge, and in 1838 published the first of a numerous list of introductory books for the study of the Greek, Latin, Hebrew, German, French, and Italian languages. These works were extensively used in England and America. He next prepared a series of school classics, combining portions of the best Greek and Latin authors; and the full classical series of Mr. Arnold covers the entire ground from first lessons to accomplished scholarship. In addition to these labors, he was an occasional writer on religious and ecclesiastical questions, and published a volume of sermons.

ARNOTT, Neil, a Scotch physician and popular writer upon science, born near Montrose in 1788. He studied medicine in Aberdeen and London, paying special attention to natural philosophy, and through the influence of his instructor, Sir Everard Home, was appointed surgeon in the naval service of the East India company. The position gave him opportunity for scientific observations in different parts of the world. In 1811 he began to practise in London, but continued his scientific investigations. His "Elements of Physics, or Natural Philosophy, General and Medical, explained in plain or non-technical language" (1827), contained the substance of lectures previously delivered, and was a successful attempt to illustrate scientific principles in the language of common life. It was translated into different languages, and passed through five editions in England within six years. In 1835 Dr. Arnott was appointed one of the senators of the university of London, in 1837 one of the physicians extraordinary to the queen, and in 1838 a fellow of the royal society. He published at the same time his "Essay on Warming and Ventilating." He has invented numerous contrivances for health and comfort, such as the stove and ventilator to which his name is given, and the water-bed or floating mattress, which has often been used with the happiest results. In 1854 he received from the royal society their Rumford medal; and in 1855 the jurors of the universal exhibition at Paris awarded him a gold medal, to which the emperor added the cross of the legion of honor.

ARNOULD, Sophie, a French actress, born in Paris, Feb. 14, 1744, died in 1803. Her father, an innkeeper, gave her a good education, in addition to which she possessed a charming face and figure, a voice of great flexibility and compass, and an unusual share of wit. Some ladies attached to the court of Louis XV., having heard her sing at evening service during Passion week, induced the royal chapel master to employ her in the choir. Here she was not long in attracting the attention of Madame de

Pompadour. Her debut upon the stage at the age of 13 soon followed, and for 21 years, between 1757 and 1778, she was the reigning favorite at the French opera. Her beauty, vivacity, and generosity attracted such men as Diderot, D'Alembert, Helvétius, Mably, Duclous, and Rousseau, who sought her society. She was as witty as she was licentious, and the most eminent poets celebrated her charms in verse. Her *bons mots*, of which many have been collected, are brilliant and pointed. At the commencement of the revolution she retired to a country house at Luzarches, which had formerly been a parsonage, and over the door of which she inscribed the words, *Ite, missa est*, where she seems to have passed the rest of her days. One of her natural sons, a colonel of cuirassiers, was killed at the battle of Wagram.

ARNSBERG, a town of Prussia, capital of a district of the same name in the province of Westphalia, situated on a hill partly surrounded by the Ruhr, 44 m. S. E. of Münster; pop. in 1871, 4,734. The new portion of the town dates from the early part of this century. In the vicinity are the ruins of an old castle where the famous Vehmie court used to be held. The once important county of Arnsberg came in 1368 into the possession of the electorate of Cologne, and the town was subsequently for some time capital of the duchy of Westphalia, of which Arnsberg is the most populous and prosperous district.

ARNSTADT, a town of Germany, in the principality of Schwarzburg-Sondershausen, situated on the Gera and on the northern slope of the Thuringian Forest, 10 m. S. of Erfurt; pop. in 1871, 8,603. Among the most notable buildings is a church built in the 11th century. The town has a castle belonging to the reigning family, and a gymnasium with a considerable library. Arnstadt is one of the oldest towns of Thuringia, being mentioned as early as 704. It was formerly known as an emporium for the trade in timber and fruit, and has in modern times become a seat of manufactures.

ARNSWALDE, a town of Prussia, in the province of Brandenburg, 41 m. S. E. of Stettin, between three lakes; pop. in 1871, 6,522. The town has a church celebrated for its bells, a large chemical manufactory, and extensive manufactures of linen and woollens.

AROLAS, Juan, a Spanish poet, born in Barcelona, June 20, 1805, died in Valencia in November, 1849. He was a member of the order of the Piarists, and chaplain in the normal school of Valencia, and became insane five years before his death in consequence of religious exaltation. His poetical works include *Libro de amores, poesias pastoriles, cartas amatorias* (3 vols., Valencia, 1843); *Poesias caballerescas y orientales* (new edition, 1850); and translations of Chateaubriand's poems and *Moïse*. A complete edition of his poems was published in Valencia in 1860, in three volumes.

AROLSEN, a town of Germany, capital of the principality of Waldeck (which according to the

convention of 1867 is now administered by the king of Prussia), on the Aar, 12 m. N. of Walddeck; pop. in 1867, 2,148. The palace contains many works of art and a library of 30,000 volumes. In the parish church are statues by Rauch, and by Kaubach, who was born here.

ARROSTOOK, a county comprising the N. and N. E. portions of Maine, and bordering on the provinces of Quebec and New Brunswick; area, 6,800 sq. m.; pop. in 1870, 29,609. The surface is undulating, with a few mountain peaks, the loftiest of which are Chase's Mount and Mars Hill. The St. John's river forms the N. boundary and flows through the W. part of the county, and is navigable for vessels of 50 tons. It is also watered by the Arroostook, a W. tributary of the St. John's, Allagash, Mattawamkeag, and several smaller rivers; and there are many small lakes and ponds. The soil is generally very fertile, but a great part of the surface is still covered by pine forests. In 1870 the county produced 46,946 bushels of wheat, 532,151 of oats, 360,450 of buckwheat, 380,701 of potatoes, 48,052 tons of hay, 86,173 lbs. of wool, 523,510 of butter, and 53,186 of maple sugar. Capital, Houlton.

ÁRPÁD, the Magyar national hero, son of Álmos, who led the Magyars into Hungary, died, after a reign of about 18 years, in 907. He completed the conquest begun by his father, carried on wars with the Bulgarians and Moravians, conquered Transylvania, Croatia, and Slavonia, and made predatory incursions into Germany and northern Italy. He also successfully began the organization of his country. His only surviving son, Zoltán, continued the Árpád dynasty, which in 1000 assumed the royal dignity, and in 1301 became extinct in the male line with Andrew III.

ARPINO (anc. *Arpinum*), a town of S. Italy, in the province of Terra di Lavoro, 8 m. S. of Sora; pop. about 6,500. It has manufactures of woollen cloth, paper, and parchment. It was originally a town of the Volsci, and subsequently of the Samnites, from whom it was wrested by the Romans in 304 B. C. It is the birthplace of Marius and Cicero, whose brother Quintus had a celebrated villa called Arcanum.

ARPINO, Giuseppe Cesari d'. See CESARI.

ARPINUM. See ARPINO.

ARQUA, or **Arquata**, a village of northern Italy, among the Euganean hills, 12 m. S. W. of Padua; pop. 2,600. It is famous for containing the house and tomb of Petrarck. He died here at his villa in July, 1374, and was laid in a sarcophagus of red marble, raised on four pilasters, on an elevated base.

ARRACK (Arabic, literally perspiration), a strong spirituous liquor distilled from fermented rice and from *toddy*, the fermented sap of the cocoanut tree, and also from rice and sugar or rice and molasses fermented with cocoanut juice. The word is used as a generic term for all distilled liquors, as there are arracks of grapes, berries, figs, dates, and even of wild flowers, in various parts of the East.

Arrack is sometimes made by adding different bitter principles and mastic to the fermenting liquor, putting it into leather bottles, and allowing it to undergo slow fermentation under the earth for a year, and then subjecting it to a crude distillation. It is largely imitated in various parts of Germany and Holland. The arrack of commerce is derived from Batavia, Goa, Ceylon, Madras, and Colombo. The best arrack in the Levant is obtained from the island of Scio. In order to prepare it for the long voyage some oil is added, which on the addition of warm water often imparts a disagreeable oily taste and smell. It is used in the composition of punch and for medical and culinary purposes. Anise seed and various aromatic herbs are sometimes steeped in it to improve its flavor.

ARRAN, an island forming part of the Scotch county of Bute, and lying in the great bay between the peninsula of Cantyre and the main coast of Scotland, 5 m. E. of the former, from which it is separated by Kilbrannan sound, and 13 m. W. of the latter, from which it is separated by the frith of Clyde. Its greatest length is about 21 m., greatest width about 12 m. The surface is high and rocky, and the scenery wild and picturesque. In the N. part the rugged mountain Goatfell rises to a height of 2,865 ft. The coast rises in many places into bold basaltic cliffs; in others it is low and sandy. The island, of which a large portion is the property of the duke of Hamilton, is divided into two parishes, Kilmory and Kilbride; total pop. about 5,500, supported by the products of small farms, and by trifling local industries. The three villages are Brodieck, Lamash, and Shedog. Many ancient monuments, supposed to have been erected by the Druids, are found in Arran. Gaelic is the ordinary language of the people, though English is generally understood.

ARRAN, Isles of, three small islands lying at the entrance of Galway bay, off the W. coast of Ireland; total area, about 18 sq. m. The largest is Inishmore, the northern island; the next in size, Inishmair, lies in the centre; and the southern one is called Inishere. They are low and barren, producing only potatoes and the most hardy grain; yet the greater part of their surface, which is divided into plots generally less than an acre in extent, is under cultivation by a wretched population of about 3,200, who live in miserable huts. On one of the northern cliffs of Inishmore stands a very ancient fort built by the Belgæ, it is supposed, early in the 1st century. Other structures of equal age are found in all three islands; and there are also numerous ruins of the oratories, dwellings, and churches of early Irish hermits, many of whom retired to these isolated places in the 6th and 7th centuries, giving to Inishmore especially the name of Arran of the Saints (*Arran-na-naomh*). The Irish earls of Arran take their title from these islands.

ARRAN, Earl of, the title of the holders of the Scotch peerage of Arran, created for Sir Thomas

Boyd in 1467, but in 1503 passing by royal decree from his son, who had displeased the king, to the house of Hamilton, the successive heads of which bore this as their chief title till the higher rank of marquis and afterward of duke of Hamilton was conferred upon them.—**James Hamilton**, second earl of his name, died Jan. 22, 1575. He was appointed regent of Scotland upon the death of James V. in 1542, and guardian of Mary Stuart, to whom he endeavored to marry his son. Finding this impossible on account of the intrigues of Henry VIII. of England and the earl of Lennox, who also wished by this marriage to obtain the Scottish crown for their own children, Arran finally consented to her union with the dauphin of France, afterward Francis II. For his aid in promoting this alliance, the French king made him duke of Châtelleraut, in Poitou, and this French title is still borne by the dukes of Hamilton.—**James**, son of the preceding, conceived a violent passion for Mary Stuart, and when his father failed to obtain for him her hand, he became insane from disappointment, and from the knowledge of her personal indifference to him. While in this state he was prevailed upon to enter into a plot against her throne; but becoming conscious during a lucid interval of the iniquity of the plan, he confessed his share in it. On account of his evident insanity he was only kept in a mild imprisonment; but he took no further part in political affairs.—The titles and estates of Arran passed to his brother John, who was created marquis of Hamilton in 1599. (See **HAMILTON**.)—There is also an Irish earldom of Arran, conferred on Sir Arthur Gore in 1758 (earl of the Arran Islands); but none of its incumbents have become prominent in history.

ARRAS (anc. *Nemetocenna* or *Nemetacum*, capital of the Atrébates), a city of France, capital of the department of Pas-de-Calais, and formerly of the province of Artois, on the river Scarpe, 100 m. N. by E. of Paris; pop. in 1866, 25,749. It was fortified by Vauban, and has manufactures of thread, lace, and woollens, with an important trade in grain. The woollen manufactures have been famous from very remote times, and the tapestries of Arras during the middle ages were so celebrated that the name of the town was generally given to this species of hangings. Arras has been the see of a bishop since 390. It was the seat of ecclesiastical councils in 1025 and 1490. When Louis XI. seized Artois on the death of Charles the Bold of Burgundy in 1477, Arras resisted, whereupon the king assaulted the town in person, drove out the inhabitants, replaced them by people drawn from all parts of France, and changed the name of Arras to Franchise. Robespierre was both a native and a representative of Arras.

ARRAWAKS, or **Lokono**, a tribe on the Berbice and Surinam rivers, Guiana, noted for their mild and peaceful disposition and friendship for Europeans. They were, however, formerly a

large, powerful, and warlike tribe, extending from the right bank of the Orinoco to the Surinam, and held all the Carib tribes in subjection, driving some to the Antilles. The French found them so powerful that they used them as a protection against other tribes. The Moravian missionaries in the 18th century did much to civilize them, and studied their language, printing in it various books for their converts. The fullest material for the study of their speech, which is regarded as one of the softest in America, is in the manuscripts of these missionaries preserved by the American philosophical society (Philadelpia). They were divided into families, apparently on the same principle as the Iroquois, but in greater number, as no fewer than 50 are enumerated. Descent was in the female line.

ARREST, the taking a person or thing by authority of the law and into its custody. I. In civil cases, arrest is the apprehension of a person by lawful authority for the purpose of compelling him to answer in a civil action. The present tone of the English law on the subject was probably first given by a statute of George I. (1726). That act, "to prevent frivolous and vexatious arrests," provided that no person should be held to special bail on any process issuing out of any of the superior courts, unless the cause of action were of the amount of £10, and on process of any inferior court unless it were of the amount of 40 shillings. These amounts were raised from time to time, and by 7 and 8 George IV., ch. 71, no person could be held to special bail, on process issuing out of any court, when the amount involved was less than £20. The 1 and 2 Victoria, ch. 100, abolished arrest on mesne process, but provided that if a plaintiff, who could before that act have had the defendant arrested, should show that he had a cause of action, or had sustained damages to the amount of £20, and that there was reasonable cause for believing that the defendant was about to quit England unless he were apprehended, a court might issue its warrant for the arrest of the defendant and hold him to bail in the amount of the debt or damage. This act and several others were displaced by the present act, 32 and 33 Victoria, ch. 62, which provides again that no person shall be arrested on mesne process in any action, and contains a similar provision to that just quoted from the former act of Victoria, but requiring further that the plaintiff shall show, except in suits for penalties, that the threatened absence of the defendant from the country will materially prejudice him in the prosecution of his action. But the cause of action must now be of the amount of at least £50.—In some of the United States arrest in civil causes still remains, but in New York and in many others it is allowed only in such cases as the following, or in cases of similar character, namely: in actions not arising out of contract, when the defendant is not a resident of the state or is about to leave

it; or in cases of a tortious nature, or for injuries to person and character, or for wrongfully converting property; or in actions for fines or penalties, or for the recovery of moneys or property received and fraudulently withheld by persons acting in a fiduciary capacity; or where the property sought is concealed or disposed of with the intent to deprive the plaintiff of the benefit of it; or when the defendant has been guilty of a fraud in incurring the obligation or in concealing or disposing of the property for the recovery of which the action is brought; or when the defendant has disposed of his property, or is about to do so, with the intent to defraud his creditors. It will be seen that these provisions exclude arrest in common actions of contract and debt, and this is the spirit of the recent legislation on this head.—By the constitution of the United States, the members of congress are exempt from arrest in all cases, except treason, felony, or breach of the peace, during their attendance at the sessions of the respective houses, and in going to and returning from them to their homes. In New York (and probably there are similar exemptions in every state) a member of the legislature is privileged from arrest on civil process during his attendance at the session of the houses, except on process issued in any suit for forfeiture, misdemeanor, or breach of trust in any office or place of public trust held by him; and for 14 days previous to, and while going to or returning from such session; and also for 14 days after any adjournment, or while absent on leave of his house. Ambassadors and other public ministers and their servants, and consuls and vice consuls, are also exempt from all process issuing out of a state court. Parties to suits, while attending at or going to or returning from courts or hearings before referees, or before arbitrators under a statute or rule of court, to attend the trial or hearing of their causes by these tribunals, and their witnesses subpoenaed and their attorneys and counsel, are also exempt. Attorneys and counsellors are generally exempt during the actual sittings of court, and while employed in any cause pending there. Married women are generally privileged from arrest on mesne process in all causes whatsoever, and no female can be arrested in New York for any cause except wilful injury. Soldiers and sailors in the service of the United States are exempt in any cause of debt or contract. And usually, by special statutes, voters on election day, members of the state militia, and certain public officers are also privileged.—A civil arrest may be made at any time except on Sundays and legal holidays, and at any place except in presence of a court. An officer may not break the outer door of defendant's house to arrest him in a civil case, though once in the house he may break inner doors to come at him; but after an arrest and escape, the officer may break open even an outer door to retake his prisoner. An ar-

rest of a person by a wrong name cannot be justified even though he was the person intended, unless he was commonly known by either name. The party arrested may ordinarily be released at once upon giving bail; but when the arrest is on final process, as for example when it is to enforce an execution against the person, the defendant, if he has no property, may usually be discharged by taking the benefit of such acts as are provided for the relief of poor debtors; for mere imprisonment for debt is for the most part abolished. II. In criminal cases, an arrest may be made, under certain conditions, either by a public officer by virtue of his general authority as a conservator of the peace, or upon a warrant or other express process or command, issued by a court or competent judicial officer; or it may be made by a private unofficial person upon an implied permission of the law. If any person, whether a public officer or a private person, sees another committing or attempting to commit a felony, it is not only his right but his legal duty to arrest him, even without a warrant. Indeed, if he does not at least try to arrest him, he is technically guilty of a misprison of the felony. And if a private person make an arrest for a felony, without a warrant, in good faith and upon a reasonable suspicion that the person whom he arrested had committed the offence, he will not be liable either civilly or criminally though his suspicions turn out to have been unfounded, provided the felony was actually committed by some one. Even in respect to crimes of less degree than a felony, a private person may make an arrest, though there is not in such cases the same legal obligation as in the case of felonies. Thus, in case of an affray or breach of the peace, any person may on the spot, and without any warrant, detain any of the offenders. Neither a private person nor an officer can make an arrest without a warrant when the time of the commission of the offence is fairly past. A constable is not justified in taking a person into custody without a warrant for a mere assault, unless he is present when the act is done. But constables, police officers, and the like officials may on reasonable suspicion arrest a person for a past felony, and they will be protected in such an act, unlike a private person in this respect, although no felony has been committed by anybody. Such officers may ordinarily make arrests without special authority, in order to prevent imminent breaches of the peace. An officer may call bystanders to help him in making an arrest, though he is acting without a warrant; and a refusal to give such help is indictable at common law. An officer may also apprehend any one who interferes to prevent his making an arrest, and it is said that he may even take into custody one who encourages another already arrested to resist.—It seems to be the better opinion that an officer, especially one who is commonly known to be such, like a sheriff or constable acting in his

proper precinct, and probably as well one who, from being elected or appointed in the usual way, may be justly presumed to be known to be such officer, need not show his warrant nor even declare his official character before making an arrest; for the power to make the arrest might be lost by going through the form of producing and explaining the process. If the officer have no proper warrant or authority, he is liable in damages to the person arrested; but if the party resist before investigating the officer's right, and the officer has the authority in fact, then the party is indictable for resisting the officer in the proper discharge of his duty. When an officer acts under a warrant, he is justified in executing it, though it was unlawfully issued in fact, provided it is in due and regular form on its face, and the magistrate had general jurisdiction of the case. The question of jurisdiction the officer must decide for himself and at his peril; and if the process is invalid on that ground, the officer is liable in damages. The maxim of the law that a man's house is his castle, does not hold good so far as to secure asylum to criminals; and when a felony has been certainly committed and the guilty party takes refuge even in his own house, an officer or a private person, even without a warrant, may break into the house to take him, after a proper demand for admission. An officer in such a case, acting in good faith on the positive information and charge of another, would be excused even though the party arrested were not the guilty party. But a private person, in order to justify the breaking of doors without a warrant, must in general prove the actual guilt of the party arrested, and it will not suffice for him to show that a felony was actually committed by some person, or that reasonable grounds of suspicion existed. When an officer has a warrant, he may, even before an indictment, break open doors in cases of treason or felonies or breaches of the peace; but it seems to be the law that, without a warrant and before indictment, he may not do so in the case of mere misdemeanors unaccompanied with violence. After indictment, a person guilty of an offence of any degree may be arrested in any place, and no house can give him sanctuary; and not only his own house, but the house of a third person, may in such a case be broken into, after reasonable demand, for the purpose of taking him.—To constitute an arrest, there must ordinarily be some physical force or restraint imposed upon the person, though there need not be more than the slightest. Mere words are not enough, unless upon these the party submits without the manifestation of any force. The mere laying of the hand upon the prisoner, or preventing his egress from a room, with words indicating the intent to arrest him, is sufficient. If an officer attempts to arrest one committing a felony, and he takes to flight to escape arrest, the officer may, after demanding that he stop and

surrender, shoot him to compel him to do so. But the officer may not do this in the case of a mere misdemeanor. And if an officer or other authorized person, in attempting to make an arrest, is resisted, and in overcoming the resistance, and in using what seems to him to be necessary force, kills the man, he will be held innocent; and if a person already arrested attempts to escape, an officer is justified in killing him if that is necessary to prevent his escape. But whenever an unlawful arrest is attempted or made, as for example when an officer arrests for a misdemeanor without a warrant, and neither on fresh pursuit nor when a breach of the peace is threatened, the party arrested may lawfully resist; and if in making such resistance he take the officer's life by mischance, it is only manslaughter. When a prisoner is arrested without a warrant, he should be handed over without delay to some magistrate. When the arrest is made under a warrant, all its requirements must be observed, and such a process usually directs the officer to take his prisoner to some court or justice.—It is a common practice for police officers and constables to search a prisoner immediately after his arrest, and take from him everything found in his possession. There are several English cases reported on this subject, and it is laid down in them that there is no legal authority for such a proceeding, unless possibly it be in those cases where the things taken are probably the fruits of the crime with which the prisoner is charged. In several such cases in England the judges have severely denounced the practice, and have ordered money especially to be returned to prisoners where their possession of it did not appear to have any connection with the offence for which they were taken, and on the ground that therefore there was no possible justification for depriving them of it.

ARRHIDÆUS, Philip, a natural son of Philip of Macedon and the dancing girl Philinna of Larissa, died in 317 B. C. After the death of Alexander the Great in 323, the Macedonian troops in the East nominated Arrhidæus king, with the proviso that the child with which Alexander's wife Roxana was pregnant should be associated with him in the government. The claims of Arrhidæus were strengthened by the fact that his wife, Eurydice, was the granddaughter of Philip's elder brother and predecessor. Being of very feeble intellect, he was a mere puppet in the hands of Perdicaeus. On the death of the latter (321), Arrhidæus and Eurydice were in Cappadocia, where Antipater, the regent of Macedonia, found them and took them over with him to Pella. After his death (319), the regent Polysperchon and the dowager grandmother, Olympias, set up, in preference to Arrhidæus, Alexander, Roxana's young son. Arrhidæus and Eurydice protested, and called in the aid of Cassander, Antipater's disinherited heir, but, falling into the hands of Olympias, were both murdered by her orders.

ARRIA, a Roman woman who immortalized herself by suicide, A. D. 42. Her husband, Cæcina Pætus, was condemned, as a traitor to the emperor Claudius, to put an end to his own life. As Cæcina hesitated to do it, his wife took up the dagger and stuck it to the hilt in her own bosom. Handing it back to her husband she said, *Pate, non dolet* ("Pætus, it does not hurt"), and expired. Pætus at once followed her example.

ARRIAN (FLAVIUS ARRIANUS), a Greek philosopher and historian, born in Nicomedia, Bithynia, about A. D. 100. He served under Hadrian and the Antonines, obtained the Roman citizenship, was prefect of Cappadocia, fought successfully there against the Alans, and after holding the consulship retired to Nicomedia about 150, and devoted himself to letters. Being a pupil and friend of the Stoic Epictetus, he published the philosophical lectures and an abstract (*Enchiridion*) of the practical philosophy of his master, and wrote dialogues, of which only fragments have reached us. He also published works upon history, geography, tactics, and hunting. The best of them is his excellent history of the campaigns of Alexander the Great. The Athenians made him a citizen of Athens under the name of his model in composition, Xenophon, his book being likewise called *Anabasis*. With this work his *Indica* is closely connected, in which he describes the Hindoos, their institutions and customs, as they were found by Alexander. He also wrote a history of Bithynia, an account of the circumnavigation of the Black sea ("The Periplus of the Euxine Sea"), "The Order of Battle against the Alans," and other smaller works.

ARRIVABENE, Giovanni, count, an Italian political economist, born in Mantua in 1789. In 1821 he was imprisoned seven months in Venice for refusing to denounce Silvio Pellico, of which 40 years later he published an account (*D'une époque de ma vie*, Brussels, 1861). Sentenced to death by contumacy in 1824, he spent some time in France and England, and has been since 1827 a resident and since 1840 a naturalized citizen of Belgium. He translated into Italian (Lugano, 1836) Mill's "Elements," and into French Senior's "Fundamental Principles of Political Economy;" and has written on benevolent societies and the amelioration of the working classes, besides *Situation économique de la Belgique* (Brussels, 1843).

ARROO, ARRU, or AROE, a group of about 80 islands in the Malay archipelago, north of Australia, between lat. 5° and 7° S., and lon. 134° and 135° E. At the end of them is a considerable reef of coral, where pearls and tripang abound. The products are pearls, mother-of-pearl, tortoise-shell, birds of paradise, and tripang. Dobbo, a town in the island of Wamma, is the entrepot of the islands, and imports calicoes, iron, hardware, and gunpowder, shipped from Singapore. The population numbers about 14,000, a few of whom are Chris-

tians. There are two or three native teachers from Amboyna.

ARROWROOT, a name loosely applied to the starch extracted from a number of roots and grains, as the maranta, manihot, tacea, arum, potato, &c. It was originally limited to the starch of the *maranta arundinacea*, a plant which grows in the East and West Indies, and which was considered a specific for the wounds caused by poisoned arrows. It is a simple food, in high repute for invalids. Not containing nitrogen, it is well adapted for producing fat and promoting the warmth of the body. According to Liebig, 4 lbs. of it contain as much carbon for supplying animal heat by its combustion as 15 lbs. of animal flesh. In its preparation the tubers are mashed, and the pulp is soaked in water. This dissolves out the starch, which is separated from the fibre by straining. After settling, the clear water is drawn off, and the starch washed with fresh water and again allowed to settle. It is finally dried in the sun.

Maranta arundinacea.

The most common adulterations are with the cheap potato starch, sago, and manioc or tapioca, all which can be detected by the microscope. The granules of the potato are of very irregular, ovoid, and truncated forms, and of various sizes, from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in diameter, while the particles of the arrowroot are very regular ovoid forms, and of nearly equal sizes. Dilute nitric acid is also a good test. When triturated with it in a mortar, arrowroot changes into an opaque paste, which is some time in becoming viscid; but potato and flour starch thus treated form immediately a transparent, thick paste. From the inferior starches alcohol extracts an unwholesome oil of disagreeable odor, but none from arrowroot. The composition of the fresh root was ascertained by Benzon to be in 100 parts as follows: volatile oil, 0.07; starch, 26; vegetable albumen, 1.58; a gummy extract, 0.6; chloride of

calcium, 0.25; insoluble fibrine, 6; and water, 65.5. Of the starch 23 parts are obtained in the form of powder, and the other 3 are extracted in the form of paste from the parenchyma with boiling water.—There is a so-called arrowroot brought from Florida, derived from a

Florida Arrowroot (Coontie) and Fruit.

plant allied to the sago palm, and sometimes known as coontie. The plant grows among the everglades in great profusion. It is of an inferior quality, containing only 12 per cent. of starch.

ARS. See ARS-SUB-MOSELLE.

ARSAMAS. See ARZAMAS.

ARSENIC (Gr. *ἀρσενικόν* or *ἀρρηνικόν*, male, from its power in destroying), the common name of the white oxide of arsenic, or arsenious acid. In ancient times the name was applied to a reddish-colored mineral compound of arsenic and sulphur, a substance in use then as a medicine, and also in painting. Metallic arsenic occurs native in veins in the crystallized rocks and older slates, and it is also prepared by subliming its oxide in presence of a reducing flux, and protected from the air. Many modern chemists do not regard it as a metal, though it is commonly treated as such. Combined with oxygen, it unites with metals, forming arsenites and arseniates of these metals, but is never itself the base of any salt. The ores of the metal are not therefore carbonates and sulphates of its oxide, but combinations of the metal itself with sulphur, forming the sulphuret, and this combined with iron, cobalt, or nickel; or they are oxides of the metal, or else compounds of its oxides with other metals. It is remarkable as the most volatile and one of the most combustible of the metals, is readily sublimed at a temperature of 360° F., apparently before it melts, and at a greater heat it takes fire and burns with a pale blue flame. In subliming, it gives out dense fumes of a peculiar garlicky odor, which distinguish it from other substances even when present in very minute quantity. It is more brittle than antimony, and may be reduced to fine powder in a mortar. Freshly prepared, it has a brilliant metallic appearance, a bluish-white color, and crystalline structure; but in the air the metal becomes black and crumbles to powder. In water it may be kept without change. Its specific gravity is 5.96. It is the softest of the

solid metals, its hardness being rated on the mineralogical scale at 3.5. Arsenic readily combines as an alloy with other metals, rendering them more fusible and brittle. Its presence is particularly injurious in iron ores, making the cast metal exceedingly brittle; but it gives great fluidity to the melted iron, so that for fine castings that do not require much strength, but sharply defined and delicate outline, it is sometimes desirable. It also increases the brightness of some alloys. It is not employed for any useful purposes in the metallic state.—Arsenious acid, or white arsenic, is the most common combination of this metal. It is the sublimate, which escapes when arsenic is heated in the open air. The metal combines in the proportion of 1 equivalent with 3 of oxygen, the compound consisting of arsenic 75.76 per cent, and oxygen 24.24 per cent. The sublimate, after exposure, is a white powder, but may be collected in the form of a glassy, transparent cake, or crystallized in octahedrons. It is partially soluble in boiling water, and less so in cold water. The solution is slightly acid, having but a feeble reaction upon litmus paper. The following are some of the most important tests given for detecting the presence of this poison: The blowpipe develops its peculiar odor, with little liability of mistake, in arsenical matters, heated on charcoal. It also reduces the metal, and causes it to condense in the form of a metallic ring in the cold part of a glass tube, in which the substance containing arsenious acid has been placed with carbonate of soda and charcoal, and heated. The presence of arsenic may be shown by this method, when the particle containing it is so small as to be invisible to the naked eye, in the following manner, communicated by Prof. A. K. Eaton of New York: The microscopic particle is placed in a bulb of a small glass tube, and a fine splinter of charcoal is placed by the side of it. The whole should then be thoroughly dried. The neck of the bulb is next to be drawn out to a capillary tube, and cooled. On applying heat to the matter in the bulb, this produces by sublimation a plainly visible arsenical ring in the fine bore of the tube. The acid is precipitated from its solutions by sulphuretted hydrogen in the form of tersulphuret of arsenic of a lemon-yellow color. This is a very accurate test, and is so delicate that the yellow tint is apparent when only $\frac{1}{100,000}$ of the acid is present, and the precipitate when the arsenious acid is in the proportion of 1 part to 80,000 of water. It is precipitated in a white powder by excess of lime water, when forming $\frac{1}{5000}$ part of the liquid. Ammonio-sulphate of copper gives an apple-green precipitate, apparent when the acid forms $\frac{1}{12,500}$ part. A still more delicate test is that of Prof. Reinsch, to place a slip of bright copper leaf in the aqueous solution acidulated with hydrochloric acid; a gray film of arsenic is deposited upon the copper, showing the presence of less than $\frac{1}{100,000}$ part of the acid. It is affirmed that

even $\frac{1}{250,000}$ part of arsenic will not escape detection by this test. Nitrate of silver gives with it a yellow precipitate. It should be borne in mind, in attempting to determine the presence or absence of arsenious acid in any mixture in which organic substances, particularly those which are not volatile, are present, that some of these substances often produce very similar reactions, and, on the other hand, that they prevent or modify those which arsenious acid should produce in mixtures where no organic substances are present.—“Marsh’s apparatus” has been long known as affording an easy means of detecting the presence of arsenious acid. The process depends on the property possessed by arsenic of forming a gas with hydrogen, and depositing itself in the metallic state upon the surface of a cold plate held over the flame of the burning gas. Hydrogen is prepared in the usual way, with granulated zinc and diluted sulphuric acid, in a glass flask provided with a tube of glass drawn out to a small orifice at its outer end; or a mere tube itself may be used, bent in the form of the letter U, one end drawn out, the other left open for introducing the materials, and closed with the thumb when in use. The hydrogen evolved should first be tested by burning it against a porcelain plate to prove that it is free from arsenic, and then the suspected liquid is to be introduced into the apparatus. If it contain any traces of arsenious acid, it will be shown by the bluish-white color of the flame, by the fumes of the acid, and brown shining spots of arsenic of metallic appearance will be deposited upon the porcelain plates. By heating the glass tube with a spirit lamp, metallic arsenic will be deposited in the colder part of it, forming a beautiful incrustation. The tube may be cut off at this point, the arsenic be converted into arsenious acid by heat, dissolved in hot water, and tested by the ammonio-sulphate of copper and nitrate of silver. This apparatus has been modified by Dr. Ure, so that the gas may be made at will to pass through the solutions by which the arsenic is precipitated, or to deposit the metallic incrustation in the tube, or the spots upon the plate. In its most simple form, however, it is a very useful contrivance for detecting arsenic. Antimony combined with hydrogen produces a spot that may be confounded with that of arsenic; but a solution of hypochlorite of soda instantly dissolves arsenical spots, and has no effect upon those of antimony. The arsenical spots also are volatilized at a temperature of 500° applied by a bath of olive oil, while the antimonial are unchanged. The proper solvent for organic matters supposed to contain arsenic is a mixture of 3 parts of hydrochloric and 1 part of nitric acid, and the quantity of this should be equal in weight to the organic substance, which before being dissolved should be cut into small pieces and dried at a gentle heat. The mixture being distilled, the arsenic, if present, comes over in the form of the volatile tetrachlo-

ride, which is then to be converted into the tersulphuret by sulphuretted hydrogen.—Arsenious acid is manufactured on a large scale at Altenburg and Röchenstein, in Silesia, from the ore called arsenical iron. In many other places it is obtained as a secondary product in the treatment of cobalt ores, and of other metallic ores with which arsenic is associated. The process consists in roasting the ore in large muffles, 10 ft. long and 6 ft. wide, in charges of 9 or 10 cwt. each, and collecting the vapors as a sublimate upon the walls of a succession of chambers, arranged in a tower through which they pass, and from which the uncondensable gases escape by a chimney. The muffles are placed inclining upward from their mouth, and are left open for the passage of heated air to aid in subliming the arsenic and converting it all into arsenious acid. A charge is worked off in about 12 hours, and is immediately followed by another. Charcoal is the fuel used, and as very little more heat is required than what is evolved by the chemical changes, the quantity consumed is very small. The purest arsenic is found in the flues and chambers nearest the furnace; in the upper chambers it is intermixed with the condensed sulphurous vapors. To purify it for market, it is all sublimed again. It is placed in cast-iron or porcelain pots, which hold $3\frac{1}{2}$ cwt. each, and these are set vertically in a furnace. They open above into sheet-iron drums, which serve as condensers, and which are connected by a funnel with the condensing chamber. The fire must be carefully regulated to maintain the proper temperature for the acid to sublime in the form of a glassy cake. If the heat is too high, metallic arsenic is apt to be sublimed and mixed with the acid, appearing in dark spots. This must be picked out, or the whole sublimed over. The preparation of arsenious acid is a most dangerous occupation. The workmen employed generally die before the age of 40; indeed, their mean term of life is stated to be only from 30 to 35 years. Dumas states that they are compelled to avoid alcoholic drinks, and live principally upon leguminous vegetables, with plenty of butter, taking very little meat, and that very fat; and to each man two small glasses of olive oil are administered daily. In removing the acid from the chambers the workmen are completely enveloped in a dress and helmet of leather, the latter furnished with glass eyes. The passage for the air is protected with a wet sponge, by which it is filtered as it passes to the mouth and nostrils.—Arsenious acid is also found native, crystallized in octahedrons and capillary ferns, at Andreasberg, in the Hartz, and at mines in Hungary and Bohemia. Combined with iron and sulphur, it forms the common ore of arsenic, called arsenical iron, or mispickel, which is of frequent occurrence in veins of iron pyrites, and of copper, lead, silver, zinc, cobalt, nickel, and tin ores. This ore is found in many localities in Connecticut and New Hampshire particularly, but is

not rare in any of the New England states, or wherever pyritous ores are found along the range of the primary rocks of the Appalachian chain. The acid is also found in the ashes of many plants; in certain soils and mineral waters; and Orfila has detected it in the earth of graveyards. Its diffusion in minute quantities is very remarkable.—The uses of arsenious acid are principally in medicinal preparations, such as Fowler's solution, the basis of which is the arsenite of potash; or it may be given in substance in the dose of $\frac{1}{10}$ of a grain, combined with something to increase its bulk. Externally, arsenious acid is used as a caustic and forms the important ingredient in many "cancer cures." It is, however, a very painful application, and in the large majority of cases this method of removing tumors possesses no advantage over the knife. It may be absorbed from the surface to which it is applied, and give rise to the usual symptoms of arsenical poisoning. Internally, it is used chiefly in skin diseases, and in malarial fevers or the cachexia arising therefrom. In these affections it displays decided efficacy. It is also used occasionally in other diseases as a tonic. The symptoms which denote that its use has been carried sufficiently far are a peculiar swelling and stiffness of the face and eyes, and some irritation of the digestive apparatus.—The statements of Von Tschudi in regard to the habitual use of arsenic by the peasants of Styria, formerly regarded as unworthy of credit, have been confirmed by subsequent observers. Dr. C. MacLagan has published in the "Edinburgh Medical Journal" for September, 1864, an account of two cases, in one of which between four and five grains, and in the other six grains of white arsenic were taken in his presence. The urine passed by each of these men after taking the dose was analyzed, and found to contain the drug. They stated that they took a dose once or twice a week, and one of them said that the good effects lasted for eight days. They were both healthy. It is said to be given to horses to improve their wind and the smoothness of their coats.—Arsenic is sometimes chosen for criminal poisoning on account of its tastelessness. Its symptoms in the majority of cases, however, are tolerably characteristic, and it is almost sure to be detected by proper chemical tests. The symptoms and post-mortem appearances observed in the majority of fatal or severe cases are those of the most violent gastro-intestinal irritation, with proportionate depression of the circulation, intense burning pain of the stomach, obstinate vomiting, and extreme depression. In a few cases, however, death takes place rapidly by collapse, and there are no characteristic post-mortem appearances. When a poisonous dose of arsenic has been swallowed, recourse should be had to emetics or the stomach pump, unless vomiting takes place spontaneously. Demulcent drinks may be given until the proper antidote can be procured. This is the hydrated sesquioxide of iron, which should be

kept at hand in the moist condition by every apothecary. The materials for making a fresh supply, namely, a solution of some persalt of iron, for instance the persulphate or the tincture of the chloride, and water of ammonia, should also be ready, since the oxide is most efficacious when freshly prepared. The two solutions should be mixed, and the resulting precipitate, after being rapidly filtered and washed, administered in the form of a paste. Recently precipitated magnesia has been proposed as an antidote. A mixture of chalk and castor oil is said to mechanically envelop the particles of arsenic and render them harmless. The effect of the peroxide of iron in neutralizing the action of arsenious and arsenic acids is seen in the harmless nature of the chalybeate waters of Wattwiller in Alsace, in which arsenic was found by Lassaigle to the amount of 2.8 per cent.—A milder grade of poisoning has resulted from the use of arsenical salts as pigments on wall paper or articles of millinery.

ARSINOË. I. A concubine of Philip, the son of Amyntas, who became the wife of Lagus, a Macedonian general, and the mother of Ptolemy I, king of Egypt. She was said to have been pregnant at the time of her marriage, and her son Ptolemy was generally regarded as the brother of Alexander. **II.** A daughter of Ptolemy I, king of Egypt, was married to Lysimachus, king of Thrace, who had cast off his former wife Amastris that he might espouse her. Arsinoë, being determined to secure the Thracian sceptre for her own issue, caused her stepson Agathocles, the son of Macris, to be put to death. Lysandra, the widow of Agathocles, fled to Syria with her children, and implored Seleucus to avenge the murder of her husband. A war ensued between the Thracian and Syrian monarchs, in which Lysimachus lost his life (281 B. C.). After this catastrophe Arsinoë sought refuge in Cassandria, a city of Macedonia, where, with her sons by Lysimachus, she remained in security for some time. But Ptolemy Ceraunus, having in 280 assassinated Seleucus and seized the crown of Macedonia, desired to gain Cassandria and get the heirs of Lysimachus into his power; he made an offer of his hand to Arsinoë, who accepted it. No sooner, however, did Ceraunus find himself in possession of the city than he caused the children of Lysimachus to be slain in the presence of their mother. Arsinoë now fled from Cassandria to Samothrace, whence she proceeded to Egypt. Here she was kindly received by her brother Ptolemy Philadelphus, the king, who speedily made her his queen. **III.** A daughter of Ptolemy Evergetes, wife of her brother Philopator, whom she accompanied to the war against Antiochus the Great in 217 B. C. Some years later a courtier named Philammon put her to death by order of the king; but her murder was subsequently avenged by her friends, who killed Philammon and all his family. She was the mother of Ptolemy Epiphanes by Philopator. **IV.** A daughter of

Ptolemy Anletes, was proclaimed queen by the Alexandrians after her brother Ptolemy Dionysius had become prisoner to Cæsar (47 B. C.). She subsequently, however, fell into the hands of the conqueror, was carried to Rome, and served to adorn his triumph (46). Her deportment excited the sympathy of the Roman people, and Cæsar permitted her to return to Egypt. In 41 Antony, at the instigation of her sister Cleopatra, had her taken from the temple of Diana at Miletus, whither she had fled for refuge, and put to death.

ARSINOË. I. An ancient city of Egypt, capital of the nome or district of Arsinoïtis, W. of the Nile, and not far from Lake Meris. Ptolemy Philadelphus gave it that name in honor of his favorite sister and queen Arsinoë. Originally, however, it was called Crocodilopolis by the Greeks, because the crocodile there received divine honors from the Egyptians. The ruins of the city may be seen in the vicinity of the modern Medinet el-Fayoom.

II. An ancient city of Egypt, capital of the Heropolite nome, at the N. W. extremity of the Red sea, near the site of the present town of Suez. Ptolemy Philadelphus considerably enlarged and improved it, and gave it its name. Arsinoë was connected with the Nile by the Ptolemæan canal, and was long the great eastern emporium of Egypt. Its revenues belonged to Queen Arsinoë and her successors.

ARSON (Lat. *ardere*, to burn), at common law, the wilful and malicious burning of another's house. House is to be understood in general to mean a dwelling house, and it included at common law all the outhouses that belonged to the dwelling, even though they were not under the same roof or joined to it, as barns and stables containing hay or corn of the owner of the house; and anciently even the burning of a stack of corn was arson. The offence was for a long time and until very lately punished by the English and American law with death. The law on the subject is not now so simple as it once was; for malicious burnings not merely of dwellings, but of churches, warehouses, public buildings, vessels, crops, and many other kinds of property are now made the subjects of express statutory provisions, and usually named arsons; and the subdivisions of the subject are very minute, and the character of the different offences in the different cases is very nicely distinguished. Arson is still used as a word of description, but the statutes do not always employ it; and indeed many of the offences which they refer to were not arsons at common law at all.—The English law as to malicious burnings of all sorts of property has been revised and consolidated in the single act of 24 and 25 Victoria, ch. 97 (1861). It provides that the unlawful and malicious setting fire to any dwelling house, any person being therein, is a felony. It punishes also the burning of churches or other places of divine worship, warehouses, outhouses, farm buildings, or any building used in

carrying on trade or manufacture; crops of hay, grass, corn, or grain, or any vegetable produce, whether cut or standing; woods, coppices, heath, gorse, or furze; stacks of corn, grain, or hay; turf, peat, charcoal, coal mines, and other kinds of property; and the penalty in almost all these cases is penal servitude for life or for not less than five years, or imprisonment for any term not exceeding two years, with or without hard labor. The statutes in the United States include not only the burning of dwelling-houses, but also the burning of jails, state houses, court houses, school houses, and other public buildings, outhouses and edifices of all descriptions, and in some of the states ships and water craft of all kinds. In many of the states recent statutes of this character also provide for cases of burning or setting fire to buildings with the intent to defraud insurers. In Louisiana and Maine burning a dwelling house may be punished with death; but generally that penalty has been abolished, imprisonment for life or for a shorter term being substituted in its place.—The statutes of two or three of the states will fairly represent the condition of the American law on the subject. In Maine any person who sets fire to the dwelling house of another, or to any building adjoining thereto, or to any building owned by himself or another, with the intent to burn such dwelling house, and it is thereby burned in the night time, shall be punished with death. But if the accused proves to the jury that there was no person lawfully in the dwelling house at the time, or if the offence was committed in the day time, the punishment shall be imprisonment for life. The statute of California provides that every person who shall wilfully and maliciously burn or cause to be burned in the night time any dwelling house in which there shall be at the time any human being, is guilty of arson in the first degree. Such burning of any dwelling house the property of another, in the day time, or such burning either in the day or night of any office, shop, barn, stable, warehouse, stack of grain, or standing crop, the property of any other person, or of any church, school house, state house, or any other public building, or any ship, of the value in any case of \$50, is arson in the second degree, and is punishable by imprisonment for not more than ten years and not less than one. If any life is lost in consequence of any such burning, the offender is guilty of murder. Any jail or other edifice usually occupied by persons lodging there at night is deemed the dwelling house of such persons. In Massachusetts the statute enacts that if any person wilfully and maliciously burns the dwelling house of another, or any building adjoining such dwelling house, or sets fire to any building by the burning whereof such dwelling house is burned, he shall suffer imprisonment for life; and the same punishment is inflicted on such burning of certain other buildings and of barns and the like structures within the

curtilage of a dwelling house, if it is done in the night. If the commission of arson causes the death of any person, the penalty is death; but without that, it is imprisonment from seven to ten years. In New York, arson in the first degree consists in wilfully setting fire to or burning in the night time a dwelling house in which there shall be at the time some human being; and every house, prison, jail, or other edifice which shall have been usually occupied by persons lodging therein at night shall be deemed a dwelling house. The punishment is imprisonment for life at hard labor. No warehouse, barn, or other outhouse is to be deemed a dwelling house unless it is actually part of one. Arson in the second degree is such burning in the day time of a dwelling house as would be arson in the first degree if done in the night; or the burning in the night time of any building not the subject of arson in the first degree, adjoining to or within the curtilage of a dwelling house, so that such dwelling is endangered.—If a man set fire to a house in the execution of a wicked design to do some other unlawful act—as for example, if, in the burning of his own house to defraud an insurance company, he burns another's—he is guilty of arson. If one sets fire to a hay stack situated so near the house of another that it is likely to carry the fire to that, and it does in fact, he is also guilty. When the house burnt is said to be another's, it is not meant that it shall be the absolute property of another, but only another's house or dwelling for the purpose of habitation or occupation, and a special property is ordinarily sufficient. As to dwelling houses, it has been held that a building designed for that purpose, but not yet finished and never yet occupied, is not a house of which arson may be committed at common law; and the same doctrine was held in the case of a building erected for a dwelling house, but which was not occupied as such at the time of the burning, and had not been for ten months previously. As to the burning, it is not essential to the offence that the house should be entirely consumed. It is enough if the fire takes effect so as to burn, that is, destroy by fire, in any degree.

ARS-SUR-MOSELLE, a town in Alsace-Lorraine, administrative division of Lorraine, formerly belonging to the French department of Moselle, 5 m. S. W. of Metz, at the junction of the Mance with the Moselle; pop. in 1871, 5,330. In and near the town are important iron mines, iron forges, and paper mills. During the investment of Metz by the Germans in 1870, Ars had great strategical importance, as the railway from Nancy to Metz here crosses the Moselle; it was therefore selected as one of the principal depots of provisions for the army of Prince Frederick Charles.

ARTA (anc. *Ambracia*), a town at the southern extremity of Albania, Turkey, near the northern boundary of Greece, on the left bank of the river Arta, and 7 m. N. of the gulf of

the same name; pop. about 7,000. It is in the pashalic of Janina, under a bey appointed by the pasha. Woollens, cotton cloth, Russia leather, and clothing are the principal manufactures. Remains of ancient Greek fortifications extend along the river on one side of the town, and portions of them were used in building the castle which is near them. There are also, in another quarter, ruins of two convents, one built by the empress Theodosia in the 9th century, the other of later construction. The river is crossed, opposite the town, by a remarkable bridge 200 yards long, built by the Venetians; it rises rapidly from the low banks to a central point 100 feet above the river. In 1821, during the war of Grecian independence, Arta was besieged and partly occupied by Marco Bozzaris, and was reduced almost to ruins. Before this it was a city of considerable beauty and prosperity, but it has never since recovered, and is now a place of small importance. (See *AMBRACIA*.)

ARTABANUS, a native of Hyrcania, commander of the bodyguard of Xerxes, whom he assassinated 465 B. C. He persuaded one of the king's sons, Artaxerxes, to kill another, Darius, and then attempted to murder the survivor that he might seize the throne himself. He failed in this attempt and was slain.

ARTABAZUS. **I.** A Persian general, son of Pharnaces, lived in the reign of Xerxes I. He commanded the Parthians and Chorasmians in the expedition of Xerxes against Greece, 480 B. C., and returned to Pallene after the king had recrossed the Hellespont, to punish certain cities which had revolted after the battle of Salamis. He besieged and took Olynthus, killed the inhabitants, and gave their city to Chalcidians. He next laid siege to Potidæa, the walls of which were washed on one side by the sea. The water having for a time receded, however, he marched his troops upon the sand thus left bare between the ocean and the fortifications, and the town seemed lost; when suddenly an unusually high tide overwhelmed nearly all his army, while the Potidæans by a sally defeated the remainder. With the few troops remaining, Artabazus joined Mardonius in Thessaly. He endeavored in vain to dissuade that leader from attempting the battle of Plataea (479 B. C.), and after his defeat led the retreat of 40,000 men from the field. With a remnant of these he reached Asia after many difficulties. **II.** A Persian general in the reigns of Artaxerxes II., Artaxerxes III., and Darius Codomannus. In 362 B. C. he was sent by the first-named king against the rebellious satrap of Cappadocia, Datames, but was defeated by him. Artaxerxes III. made Artabazus satrap of western Asia, but he soon revolted, and, aided by Greek and Theban mercenaries, defeated in two battles the armies sent by the king to punish him. Losing the aid of his allies, however, by the successful schemes of his enemies, he was at last defeated and taken prisoner,

but liberated by the exertions of his brothers-in-law, Mentor and Memnon. Unsuccessful in another attempt at rebellion, he was compelled to take refuge with Philip of Macedon. But Mentor, who had joined the side of the king and had been of great assistance in the war against Egypt, secured his pardon about 349. He now returned to Persia, and afterward, in the reign of Darius Codomannus, occupied several positions of trust. His daughters married Alexander, Ptolemy, and Eumenes. He resigned his satrapy in 328.

ARTAXATA (Arm. *Ardashad*), an ancient city on the Araxes, capital of Armenia, 68 m. S. S. E. of Erivan. It was built under the direction of Hannibal while a refugee at the court of Artaxias, after whom it was named. In A. D. 58 it was destroyed with fire by the Roman general Corbulo, but rebuilt by Tiridates, who called it Neronia. In 370 it was taken by the Persians, who partially destroyed it and carried into captivity most of its inhabitants. In 450 a famous council was held here, at which the patriarch Joseph presided.

ARTAXERXES, or **Artoxerxes** (in the Hebrew Scriptures *Art'hashashtha* or *Art'ashasta*), the name of three kings of ancient Persia, signifying, according to Herodotus, "great warrior."

I. Surnamed Longimanus, was the third son of Xerxes I., and was brought to the Persian throne by the assassination of his father and elder brother Darius (see **ARTABANUS**) in 465 B. C., and died in 425. Troubles in Bactria, excited by his elder brother Hytaspes, first engaged his attention. Meanwhile Egypt, aided by the Athenians, revolted under Inarus against the Persian yoke. Artaxerxes at length compelled the Athenians to evacuate Egypt, but they continued to struggle on their own account under Cimon, until on the death of the latter (449), Artaxerxes was forced to make a disadvantageous peace. He was succeeded by his son Xerxes II. **II.** Surnamed Mnemon on account of his good memory, succeeded his father Darius II. in 405 or 404 B. C., died about 359. He is chiefly known in history from his contest with his younger brother Cyrus (see **CYRUS THE YOUNGER**), after whose bloody end in the battle of Cunaxa (401) he was left in quiet possession of the Persian throne. The Lacedæmonians had meanwhile given evidence of a design to take advantage of the Persian complications to attack the empire in the moment of its weakness; and now that the critical time was over, Artaxerxes avenged himself by a successful war against them, which hastened the decline of the Spartan power. Sparta having consented to the humiliating peace of Antaleidas (387), Artaxerxes prosecuted a war against Evagoras of Cyprus, and subsequently against the Cadusii on the shores of the Caspian sea, rendering them tributary; he then turned his forces against revolted Egypt, but failed through the unskillful management of his general, Pharnabazus, and 12 years later renewed the attempt with the same result. He

put to death his eldest son, having detected him in a conspiracy, and was succeeded by his third son Ochus. **III.** Ochus, on his accession, assumed the name of Artaxerxes. The principal events of his reign (about 359–338), which was stained by cruelty, were the quelling of a revolt raised by Artabazus, the resubjugation of Egypt, and the pacification of Phœnicia and Cyprus. He was poisoned by his favored eunuch Bagoas.—Besides these, Ardeshir, the founder of the Sassanide dynasty, is called by ancient historians Artaxerxes.

ARTEMIDORUS OF EPHESUS, a Greek geographer, flourished at the end of the 2d and the beginning of the 1st century B. C. He is said to have travelled in Spain and Gaul, and to have made voyages in the Euxine, the Mediterranean, the Red sea, and the Indian ocean, with the object of correcting the errors which former geographers had fallen into in describing them. The result of his travels and observations consisted originally of 11 books. All of these have perished, save the fragments (collected by Hudson) which Strabo, Marcian, and other ancient writers have preserved.

ARTEMIS. See **DIANA**.

ARTEMISIA. **I.** A queen of Halicarnassus, in Caria, who, as a vassal of the Persian crown, joined the expedition of that monarch against Greece with a squadron of five ships, and shone by her valor and prudence in the battle of Salamis (480 B. C.). According to a doubtful tradition, she became enamored of a youth of Abydos named Dardanus, who did not reciprocate her affection, whereupon she had his eyes put out. Afterward regretting her cruelty, she consulted an oracle as to how she should make atonement, and in obedience to the mandate of the divinity cast herself into the sea from the Leucadian rock. **II.** The sister, wife, and successor of Mausolus, king of Caria, celebrated for the excessive grief which she manifested at his loss (352 B. C.). She employed the most eloquent rhetoricians of Greece to pronounce panegyrics in his honor, and raised a monument to his memory at Halicarnassus, which was considered one of the seven wonders of the world, and from which the now general term mausoleum is derived. She survived him about two years.

ARTEMISIA, a genus of plants of the order *compositæ*, noted for bitter, tonic, or aromatic properties. *A. absinthium*, or wormwood, is a perennial plant with woody stems in clusters two or three feet high, with long-petioled, irregularly pinnatifid, silvery leaves, and small, clustered, inconspicuous flowers. Its common name is derived from its virtues as an anthelmintic. *A. abrotanum*, or southernwood, is cultivated in gardens for its aromatic foliage, and much used in Europe in beer making. *A. dracuncululus*, or tarragon, a native of Siberia, is used in pickles for flavoring. *A. Chinensis* or *moxa* produces a woolly substance on the stems and leaves which is used by the Chinese and Japanese as a moxa by

burning it upon parts of the body affected with gout or rheumatism. *A. Ludoviciana* is the common sage bush of the American plains, and is a low irregular shrub, with thick, crooked stems, growing in dry alkaline soils, which unless irrigated will produce little else. Its strong odor may be noticed at some distance away. With greasewood it serves as the principal if not the only fuel on the plains. All artemisias are easily propagated by seeds or divisions of the roots.

ARTEMISIUM, properly a temple of Artemis (Diana), the name of several places in ancient geography. The most important of them was the promontory on the N. coast of Eubœa, off which the Greek ships fought with the fleet of Xerxes, almost simultaneously with the battle of Thermopylae, in 480 B. C. The success achieved here by the Greeks was soon followed by the great victory at Salamis.

ARTERY (Gr. ἀρτηρία, from ἀήρ, air, and τηρεῖν, to keep), a blood vessel conveying the blood outward from the heart to the organs; so called because the ancients supposed these vessels to contain "spirits" or air. An artery is distinguished from other blood vessels mainly by the thickness and elasticity of its walls. When cut open, therefore, in the dead body, after most of the blood has collected in the great veins and internal organs, the artery does not collapse as a vein would, but stands open, allowing the air to pass into its cavity. It was this circumstance which led the old anatomists to believe that the arteries also contained air during life. They supposed that the air, penetrating the lungs at the moment of inspiration, was partly received by the left ventricle of the heart, and thence distributed by the arteries throughout the body, while the blood was sent out from the right ventricle by the veins. It was not until Galen, in the 2d century, opened the arteries, with some experimental precautions, in the living animal, that it became known that these vessels during life served as conduits for blood and not for air. An artery is composed of three coats, the internal or serous, the middle or fibrous, and the external or cellular. The external coat is the most resisting of the three, and prevents the vessel, under ordinary circumstances, from being distended beyond a certain point. The middle coat is distensible; but, owing to the peculiar nature of the fibres which constitute its substance, it also has the power of elastic reaction, and in the smaller arteries that of muscular contractility. In the larger and medium-sized arteries, the elasticity of their walls reacts upon the blood during the intervals of the heart's pulsation and urges it onward toward the periphery: so that the current of blood in this part of the circulation, though pulsating in character, is yet continuous, or nearly so, and merely increases in velocity with every pulsation of the heart, and diminishes, without ceasing altogether, in the intervals. In the smaller arteries, the muscular fibres of the middle coat,

under the varying influence of the nervous system, contract or relax at certain periods; thus increasing or diminishing the resistance of the vessels to the flow of blood, and causing local variations in the circulation of particular parts. When an artery is wounded the blood escapes in jets, coming with greater force at the instant of each pulsation of the heart; and it can be distinguished by this feature from hæmorrhage from the veins, in which the blood escapes in a comparatively feeble but continuous stream. If the wounded artery be of considerable size, it requires to be secured by a ligature in order to stop the flow of blood.

ARTESIAN WELLS, small holes sunk in the earth, through which currents of water, struck at great depths, rise toward the surface, and sometimes flow over; so named from the province of Artois in France (Lat. *Artesium*), in which they have for a long time been in use. Water thus pressed up must have its source in some more elevated lands, and be confined in the strata of rock through which it has percolated; precisely as water is conveyed in pipes below the surface, and pressed up

An Artesian Well.

into buildings to a height nearly equal to that at which the pipes commence. Water finds its way down into the earth by flowing into the crevices and chasms of the rocks, and by percolating through the porous strata. In a region of limestone rocks it hollows out for itself its own bed, by dissolving the limestone, and even in this way produces great caves. When forced by the pressure behind, the water is pushed up through any apertures it meets and flows out as a spring or artesian well. There are three conditions essential to the successful boring of an artesian well: 1. A fountain head more elevated than the locality where the boring is to be undertaken. 2. A moderate downward dip of the strata toward the site of the well; a steep or high angle of inclination of dip is unfavorable, as the water is apt to flow away beyond the reach of the boring, which must needs pass at an acute angle through few layers of rock. 3. Alternations of porous and impervious strata beneath the surface soil. It is sometimes the case that the head of water is at so high an elevation, that the column bursts forth from the ground as a fountain,

throwing up a continual jet. The principle is precisely that of our artificial fountains. By raising the water above the surface in a pipe, and letting it flow over, convenient water power is obtained; artesian wells are applied to this purpose at many localities in France, the water they supply being found sufficient to run heavy machinery. From the great depth at which the currents of water are reached, their supplies may be regarded as permanent. A well at Aire in Artois, France, which was bored over a century ago, has since then flowed steadily, the water rising 11 ft. above the surface at the rate of 250 gallons a minute; and at Lillers (Pas-de-Calais) one well has flowed steadily since the year 1126. In the vicinity of London it is observed that the height to which the water rises diminishes as the number of wells is increased. In 1838 the supply of water from them was estimated at 6,000,000 gallons daily, and in 1851 at nearly double the amount, and the average annual fall of the height of the water is about 2 ft. But in cases of single wells, the supply of water or the height to which it rises is seldom known to vary. From their depth, also, the water brought up is warmer than that found near the surface. This increase of temperature with the depth takes place at different rates in different places. At Paris, where the mean temperature at the surface is 51° F., the water of the artesian well of Grenelle is 82° from a depth of 1,797 ft., which is about 1° for every 58 ft. deep. At St. Louis, the temperature of the water at 1,515 ft. is 18·18° F. higher than the mean temperature at the surface, making the increase 1° for every 83·3 ft. descent. At Charleston, S. C., the temperature of the water at the surface is 68° F.; at 500 ft. it is 73·5°; at 1,000 ft., 84°; and at 1,106 ft., 88°. The average rate of increase is about 1° for every 52½ ft., as stated by Prof. Hume of the state military academy. The hot springs that flow out to the surface in many parts of the world are natural artesian wells rising from great depths. In Virginia these springs are found along the lines of great faults or breaks in the stratification of the rocks, by which formations usually separated by thousands of feet are brought into contact with each other. Warm waters obtained by artesian wells have been applied to useful purposes connected with manufacturing. They are especially valuable where pure water of a uniformly warm temperature is required. In Württemberg large manufactories are warmed by the water being sent through them in metallic pipes; a constant temperature of 47° is thus maintained when the temperature without is at zero. Hospitals and green-houses are also kept warm in the same manner.—The strata of clays, sands, and limestones, which form the tertiary basins of London and Paris, are particularly well arranged for furnishing water by artesian wells. Covering areas of many square miles, the slope of the strata is toward the centre of the basin, and

here, at the depth to which these reach, the waters must collect in large quantities. The strata, moreover, are not difficult to penetrate by boring. In these basins are concentrated the greatest number and the most expensive of these wells. The famous Grenelle well in the Paris basin was commenced in 1833, with the expectation of obtaining water at 1,200 or 1,500 ft., in the secondary greensand formation, which underlies the chalk, the uppermost member of this series. For the first 50 ft. the bore was 12 in., which was then reduced to 9 in. for the next 1,050 ft.; a second reduction to 7½ in. was made till the depth of 1,300 ft. was reached, where there was a final decrease to 6 in. At 1,500 ft. the government would have abandoned the enterprise but for the urgent appeals of M. Arago. It was continued till, on Feb. 26, 1841, at the depth of 1,797 ft., the boring rod suddenly penetrated the arch of rock over the subterranean waters, and fell 14 ft. In a few hours the water rose to the surface in an immense volume and with great violence, bringing up sand and mud. To check the supply a vertical pipe was raised many feet into the air, in which the water rises and flows over. The water is perfectly limpid, and flows at the rate of 500,000 gallons in 24 hours. It is used for warming the hospitals at Grenelle, as its temperature is uniformly 82° F. A well very similar to that at Grenelle, though of increased diameter, was begun at Passy, two miles distant, in September, 1854, and finished Sept. 24, 1861. The boring began at a height above the sea of 305·2 ft., and that at Grenelle at 121·3 ft.; the depth is 1,923 ft., and diameter within the tube 2·4 ft. The flow from this well began slowly, but on Sept. 27 had reached over 5,500,000 gallons per day. The yield at the mouth was greatly decreased when raised through a tube 25 ft. high; a like result followed at Grenelle, where the yield was 440 gallons per minute at the surface, but decreased to 135 gallons when forced through a tube 33 ft. high. That these two wells, though two miles apart, drew their supply from the same source, is evident both from their temperature, 82° F. in each, and from the fact that the opening of the Passy well reduced the flow at Grenelle from 135 to 100 gallons per minute, though it is anticipated that by forcing the water at Passy through a still higher tube the yield at Grenelle may be increased. This dependence of several wells upon one source is shown also in the Pennsylvania oil region, where the water from one well, when not pumped out, often finds an exit through the tubes of those adjoining. The work on both the above-mentioned wells was much delayed by accidents. When that at Grenelle was at a depth of 1,254 ft., the drill broke off and fell with 270 ft. of rods to the bottom; 15 months were spent in breaking these and removing the pieces. The tubing in the Passy well was also burst by the external pressure of sand and water, and had to be removed and new tubes

inserted, retarding the work for many months. At Kissingen, Bavaria, there is a well 1,878 ft. deep, the last 138 ft. of which passes through rock salt. The water, which flows from it at the rate of 100 cubic feet a minute, contains $3\frac{1}{2}$ per cent. of salt; its temperature is 66° F., and the whole cost of boring was about \$33,000.—Artesian wells are of peculiar value upon desert plains, and those vast prairies that rest upon porous limestone formations, through which the surface water finds its way and is lost. In May, 1858, M. Jus, a French engineer, commenced boring for water in the desert of Sahara, and on June 19 a well was sunk, from which there flowed a steady stream of pure water, having a temperature of 61° F., at the rate of 1,000 gallons per minute. Up to the present time (1872) over 75 wells have been bored in that desert, yielding an aggregate of 600,000 gallons an hour. The effect of this abundant supply of water upon the once barren soil of the desert is plainly apparent; two new villages have been built in the midst of former solitudes, 150,000 palm trees have been planted in more than 1,000 new gardens; the oases of Tameihat, Oum Thior, and Shegga have each their wells yielding from 25 to 1,000 gallons per minute. A promising feature in these wells is that water is reached at a comparatively slight depth, the one in the oasis of Sidi Nached being hardly 200 ft. deep. There is also a well at Bourne, England, which, though but 92 ft. deep, yields 537,000 gallons of pure water per day, and the pressure is sufficient to supply the town and force a stream above the highest roofs. The proprietors of the Continental hotel, Philadelphia, have lately completed a well, 8 inches in diameter and only 200 ft. deep, which supplies them with 50,000 gallons of pure water per day.—The success attending the work of the French engineers in Africa is one of great promise to those who would undertake the irrigation of the rich plains of the Colorado desert; and already a well bored by direction of the Pacific railway company at Point of Rocks, 805 m. W. of Denver, in the midst of the alkali district, furnishes abundant water for the engines on that road, the water rising to within 11 ft. of the surface. In 1855 the United States government sent out an expedition, under command of Capt. Pope, for the purpose of boring for water in the Llano Estacado, near the borders of Texas and New Mexico. The first well was sunk at a point 15 m. due E. of the river Pecos, on the 32d parallel of latitude. At the depth of 360 ft. the first stream of water was struck, which rose to the height of 70 ft. in the tubing; at 641 ft. a second stream was struck, which rose 400 ft. Five miles E. of this point a second well was bored to the depth of 860 ft., in which the water rose 750 ft.—Of the artesian wells in the United States, those at St. Louis, Louisville, and Charleston are among the most important, both from their extreme depth and the difficulties attending the sink-

ing. The well at St. Louis was completed at the expense and under the direct supervision of William H. Belcher of that city. An interesting account of its progress is given by A. Litton, M. D., in the "Transactions of the Academy of Science of St. Louis," vol. i., No. 1, 1857. The boring of this well was begun from the bottom of an open well 30 ft. deep in the spring of 1849. The bore to the depth of 219 ft. was 9 in. in diameter, then $5\frac{1}{2}$ in. for 731 ft. further, and continued at $3\frac{1}{2}$ in. till the full depth, 2,199 ft., was reached. At 550 ft., the top of a limestone layer, the water became salty; 200 ft. below this, in a layer of shale, it contained $1\frac{1}{2}$ per cent. of salt; and at 965 ft., below a bed of bituminous marl, $2\frac{1}{2}$ per cent. At the depth of 1,179 ft. the hardest rock was encountered, being a bed of chert 62 ft. thick. The work was stopped on March 12, 1854, in silicious and clayey beds belonging to the lower Silurian formation. The water is at present discharged through a 20-inch pipe at the rate of 75 gallons per minute; it is only fit for medicinal purposes, having a strong odor of sulphuretted hydrogen, and containing over 8 per cent. of mineral matter, including 6 per cent. of salt: its temperature is even at $73\text{--}4^{\circ}$ F. The total cost of this work exceeded \$10,000. The well at Louisville, Ky., has a 3-inch bore, and is 2,086 ft. deep. The water flows from it at the rate of 330,000 gallons per day, and with a force equal to 10-horse power. It is perfectly clear, though highly charged with mineral substances, being similar in composition and medical properties to the celebrated Kissingen waters, and the Blue Licks of Kentucky.—Of all the wells sunk in the United States, none is so remarkable for the difficulties encountered and successfully overcome as that at Charleston, S. C. Since 1824 five attempts have been made by the city government to obtain good water by this means. In 1848 the last operation was commenced under the direction of Maj. Welton. The strata first penetrated were alluvial sands, saturated with water, which caused them to run as quicksand. These were shut out by cast-iron tubing of 6 in. diameter, which penetrated the clays and marls of the postpliocene formation, and finally reached the depth of 230 ft., where it rested upon a rock of the cocene formation. From this point down alternations of hard rock and loose sands were met with, the latter causing the same trouble as those above, running in and filling the well, sometimes even to the height of 140 ft. up from the bottom in a single night. When it was found impossible to draw out the sands from these beds, the plan was adopted of shutting them out by tubing. The bore of the lower part, being first enlarged from $3\frac{1}{2}$ to $5\frac{1}{2}$ in., was lined with sheet-iron tubes to the depth of 700 ft. Sand flowing in at 1,020 ft. rendered it necessary to take out the tin tubing, and replace it with heavier tubes of 4 in. diameter and $\frac{3}{4}$ in. thick, which screwed one upon another; this was

done to the depth of 1,102 ft. The sinking was extended, of 3-inch bore, to 1,250 ft., the last strata being sandstones, sand, and marls, probably of the cretaceous formation. The discharge, 10 ft. above the surface, is about 1,200 gallons an hour. The water is saline, and disagreeable to the taste, but soft. Its temperature is 87°.—In Onarga, Iroquois county, Ill., 85 m. S. of Chicago, there are artesian wells that deserve especial notice, both because of their number (over 200 within a radius of 20 m.), and from the fact that they are all flowing wells, though the average depth does not exceed 70 ft. They are sunk with an auger 6 in. in diameter, and the water vein, a bed of white sand, is reached after boring through 5 ft. of surface soil, 10 to 20 ft. of common sand, 15 to 20 ft. of blue clay, and 20 to 30 ft. of hardpan, a mixture of clay and gravel. The flow, which rises several feet above the surface, varies in amount from 20 to 120 gallons per minute. It has been estimated that the daily yield from these wells is 53,400,000 gallons. It is a fact worthy of note that the district in which they are located is at a level of 92 ft. above that of Lake Michigan, and that the nearest probable fountain head is at least 200 m. distant. This dependence upon a distant source of supply is also demonstrated by the famous Chicago wells. One of these has a surface diameter of 5 in., which is reduced to $4\frac{1}{2}$ on nearing the bottom, at a depth of 711 ft. The other is 5 in. in diameter from top to bottom; the first 42 ft. are lined with an iron tube, which projects 22 ft. above the surface; from this level the water flows at the rate of 432,000 gallons per day, and with a resisting power of from 600 to 800 lbs. The site of both wells is 82 ft. above the level of the lake, and the general character of the surrounding country is flat; whence it is conjectured that they may be fed from the region of the Rock river, 100 m. distant.—Though the geological structure of Manhattan island is exceedingly unfavorable, yet several artesian wells were sunk in the city of New York years ago by Mr. Levi Disbrow. One of the oldest and deepest of these wells is at the United States hotel, known when the well was sunk as Holt's, on Pearl, Fulton, and Water streets. The boring for the first 126 ft. was in stratified sands and blue clay alternating with river mud. At this depth the surface of the rock was struck under a bed of coarse gravel; and below this the shaft was continued in the gneiss rock 500 ft. further. The upper 200 ft. of the well was bored 3 in. in diameter; the remainder was $2\frac{1}{2}$ in. The water for a time was tolerably good, but soon became impregnated with the salt river water, and at last unfit for use. At the corner of Bleeker street and Broadway a well was sunk 448 ft., of 7 in. bore—the first 42 ft. through sands and gravel, and 406 ft. through the hard gneiss rock of the island. The water, as stated by Mr. Disbrow, rose within 30 ft. of the surface,

to the amount of 120,000 gallons in 24 hours. At the dry dock, 11th street, East river, the rock, met with at 130 ft., was penetrated 200 ft. further. Many other wells of this nature have been sunk in and near the city, but with no features of particular interest.—In considering the methods of boring artesian wells, and examining the implements now used, it is interesting to note the similarity between these and those employed by inhabitants of China centuries ago. The missionary Imbert stated in 1827 that in the province of Ou-Tong-Kiao, in a district 10 leagues long and 4 wide, these wells may be counted by "tens of thousands," sunk at very remote periods for the salt water and bituminous matters which they emit. These products are met with at the depth of nearly 1,800 ft., and some of the wells that had lost them have been carried down even to 3,000 ft. From this enormous depth currents of carburetted hydrogen come up in such quantity that it is used to furnish heat for evaporating the salt water. (The gas from the Pennsylvania oil wells is often burned under the steam boilers.) Instead of using rods to sink their wells, the Chinese suspend the cutting drill, which is attached to a heavy metal rod 6 ft. long and 4 in. in diameter, by a rope or chain, which passes over a wheel. Around the drill is a cylindrical chamber, which by means of simple valves takes up and holds the broken fragments. As the rope is raised and dropped, it gives by its torsion a turn to the drill, causing it to vary its position at each stroke. When the cylinder requires to be discharged, it is easily wound out by a windlass or horse-whim. The rope is protected from wear by knobs of wood attached to it at intervals. This principle has been successfully applied in Germany to sinking holes for ventilating mines; with large drills 18 in. in diameter a hole of this size has been carried down several hundred feet.—The demand for improved methods of sinking these wells which the opening of the Pennsylvania oil region created, has resulted in the introduction of many ingenious labor-saving appliances, though the attention of the oil men has been chiefly directed toward the devising of methods by which the boring tools may be safely and quickly removed in case of accident. A general description of the processes of boring, tubing, and pumping, as practised in western Pennsylvania, may best serve to illustrate the latest advances made in the methods of sinking artesian wells. Directly over the site of the proposed well a wooden derrick or open tower is erected, 14 to 16 ft. square at the base and 30 to 60 ft. high, the four corner posts converging so as to form a square at the top $2\frac{1}{2}$ ft. in diameter, upon which rests a heavy framework for the reception of the pulley over which the drill rope is to play. Near the bottom of the derrick, and in range with the band wheel from which the power is derived, is a shaft of timber 6 or 8 ft. long, and about 8 in. in diameter, mounted on journals.

and similar in character to the common hoisting windlass. Upon each end of this shaft is driven a large pulley called the bull wheel; between these, upon the main shaft, the drill rope, a cable of from $1\frac{1}{4}$ to $1\frac{3}{4}$ in. in diameter, is coiled, the outer end passing from it over the pulley on the top of the derrick, and attached to the drilling tools. When these are to be lowered or withdrawn, it is done by means of power applied to the bull wheel. In localities where the rock is some distance below the surface, it is customary to drive down, by the aid of a suitable weight and guideway, a heavy

Boring Tools.

metal pipe, called the drive pipe; this is usually of cast iron, from 6 to 8 in. in diameter and an inch in thickness; it is driven in sections of 10 ft., and great care is needed that it be not bent or deflected, since it is to guide the drilling tools. The engine is so placed that its drive or balance wheel shall be from 20 to 25 ft. from the centre of the derrick, and at one half this distance is planted the sampson post, a heavy hewn timber from 12 to

15 in. square and 12 ft. high, the top of which is fitted to receive the working beam. This working or walking beam transmits and applies the power to the drills; it is of wood 8 or 10 in. square, and of such a length that when balanced upon the sampson post one end may stand directly over and connect, by means of a connecting rod, with a crank attached to the shaft of the drive wheel; by the revolution of this crank, which has a radius of about 20 in., a reciprocating movement is given to the further end of the working beam; on this is bolted an iron joint, to which may be attached the temper screw when drilling, or the sucker rods when pumping. The drilling tools consist of centre bits, reamers, an anger stem, jar, and sinker bar, with a socket for attaching this last to the drill rope. The centre bit is of $2\frac{1}{2}$ -inch wrought iron, $3\frac{1}{2}$ ft. long, and having a wedge-shaped cutting edge of steel, $3\frac{1}{2}$ to 4 in. on the face. The reamer, which follows this and serves to enlarge and trim out the hole, is very similar in shape, though about an inch broader on the face, which is also more blunt; the average weight of each is about 75 lbs. The anger stem, into which bits, reamers, and dislodging tools are screwed, is a wrought-iron bar about 20 ft. long. The sinker bar, a heavy rod of iron 10 ft. long, serves to increase the force of the blow; it is separated from the anger stem by an ingenious contrivance called a jar, consisting of two links or loops of iron or steel, which slide in upon each other when the drill strikes bottom, thus, by a quick blow upon the top of the anger stem, increasing the effect of the fall; and on the upward movement the sudden jerk or jar serves to loosen the tools, in case they become wedged. When connected, these tools weigh from 800 to 1,600 lbs., as the hardness of the rock requires. The drill rope is attached to the working beam by means of a temper screw, suspended from it and made fast to the rope by a screw clamp. This temper screw is about 3 ft. long, and is made with a coarse thread that works in a thin frame. At the lower end of this screw is a wheel, by which it is let down after each stroke, whereby the tension is regulated and the drill properly guided. The tools are lifted and dropped by the rocking motion of the working beam, and lowered or withdrawn by aid of the bull wheel and shaft. The sediment and battered rock is removed by means of a sand pump, which is a heavy metal tube, slightly smaller than the well bore, and about 6 ft. long, with the lower end closed by a simple valve opening upward; this is lowered and withdrawn by the drill rope, and the well-man by an examination of its contents is informed of the progress and prospects of his work. The pump is used after each drilling of 6 to 12 in. The tubing of a well consists in driving down a heavy iron pipe in sections, the joints of which are flush both inside and out. At the lower end of the first section driven down is a simple ball-valve pump, the piston

of which is connected with the working beam by jointed poles or metal rods. When it is desirable to exclude all water from above a given point, it is effected by binding around the tubing a leather bag of flax seed before

or rods. It is lowered down the well bore until the rod passes up above the ends of the two arms, when by an upward movement the two arms, when by an upward movement the two catches, being pressed forward by springs, take hold of the rod and grasp it the more firmly the greater the resistance. Fig. 2 is of service mainly in removing a detached drill or reamer; the shorter arm acts as a guide, while the hook at the end of the larger one passes below and takes hold of the lower edge of the drill. Figs. 3 and 5 are also designed for removing broken rods. In 3 the rod passes through the metal cylinder, and is prevented from falling back by the drop-catch and spring. Fig. 5 consists of an angular claw placed at right angles to the rod by which it is lowered; this is twisted under the shoulder of the rod, thus securing it as in a wrench. Fig. 4 is the ordinary lazy tongs, and is of very general service, as its construction indicates.— In addition to the contrivances above mentioned, the French engineers have introduced certain improved drills, pumps, &c. The drill invented by M. Goulet-Collet consists of a cylinder of sheet iron 6 ft. long, suspended by a chain, and armed at its lower end with an annular cutting head of steel, in which two knives or chisels are inserted at right angles across the opening. These chisels serve to cut the rock, which when finally divided rises with the water through the openings; these may be provided with valves, the instrument thus serving the double purpose of drill and pump. The method of boring by means of the diamond drill is essentially different from that described above. (See *ENGINEERING*.) When a well fails to yield a fair amount of oil or water, an increase in the flow is often effected by means of the Roberts torpedo. This is a thin water-tight cylinder of metal or paper, 4 to 6 ft. long and 2 or 3 in. in diameter, charged with powder, gun-cotton, or nitro-glycerine. It is lowered to the bottom of the well, or to a depth that will bring it opposite the desired stratum, and the well then flooded. The charge is exploded by a cap or electric spark, and the explosion often clears away the obstruction from the oil or water vein. Wells yielding only 5 bbls. of oil per day have been increased by this means to 75 or 100 bbls.— Negative artesian wells are those which serve to convey away surface waters into some absorbing stratum. They are of service about manufactories from which large quantities of

Boring Tools in Operation—Pennsylvania Oil Region.

Tools for Extracting Obstructions.

driving it down; the swelling of this closes the space between the main wall and the tube. The steam engines in use in western Pennsylvania range from 6 to 20 horse power, one of 8 horse power being sufficient to bore a well 900 ft. deep. Artesian wells have been sunk, though

very slowly, by the aid of two men and an old-fashioned spring pole.—Among the accidents liable to occur in the boring of artesian wells, are the breaking of the drills, or their detachment from the auger stem, and the loss of the sand pump or the whole boring gear by the wearing away of the drill rope.

Simplest Boring Apparatus.

At times the drill enters what is known as a mud vein, a thin stratum of mud or slicksand, which often flows in so rapidly as to enclose and bury the drilling tools. There are many ingenious contrivances for the removal of these obstructions, and the forms of several of the less complex are shown in the cut. Fig. 1 is designed chiefly for removing detached or broken pipe

or rods. It is lowered down the well bore until the rod passes up above the ends of the two arms, when by an upward movement the two catches, being pressed forward by springs, take hold of the rod and grasp it the more firmly the greater the resistance. Fig. 2 is of service mainly in removing a detached drill or reamer; the shorter arm acts as a guide, while the hook at the end of the larger one passes below and takes hold of the lower edge of the drill. Figs. 3 and 5 are also designed for removing broken rods. In 3 the rod passes through the metal cylinder, and is prevented from falling back by the drop-catch and spring. Fig. 5 consists of an angular claw placed at right angles to the rod by which it is lowered; this is twisted under the shoulder of the rod, thus securing it as in a wrench. Fig. 4 is the ordinary lazy tongs, and is of very general service, as its construction indicates.— In addition to the contrivances above mentioned, the French engineers have introduced certain improved drills, pumps, &c. The drill invented by M. Goulet-Collet consists of a cylinder of sheet iron 6 ft. long, suspended by a chain, and armed at its lower end with an annular cutting head of steel, in which two knives or chisels are inserted at right angles across the opening. These chisels serve to cut the rock, which when finally divided rises with the water through the openings; these may be provided with valves, the instrument thus serving the double purpose of drill and pump. The method of boring by means of the diamond drill is essentially different from that described above. (See *ENGINEERING*.) When a well fails to yield a fair amount of oil or water, an increase in the flow is often effected by means of the Roberts torpedo. This is a thin water-tight cylinder of metal or paper, 4 to 6 ft. long and 2 or 3 in. in diameter, charged with powder, gun-cotton, or nitro-glycerine. It is lowered to the bottom of the well, or to a depth that will bring it opposite the desired stratum, and the well then flooded. The charge is exploded by a cap or electric spark, and the explosion often clears away the obstruction from the oil or water vein. Wells yielding only 5 bbls. of oil per day have been increased by this means to 75 or 100 bbls.— Negative artesian wells are those which serve to convey away surface waters into some absorbing stratum. They are of service about manufactories from which large quantities of

impure liquids are discharged, the flow of which upon the surface would prove a nuisance.

ARTEVELDE. I. **Jacob van**, a citizen and popular leader of Ghent, and for a time almost ruler of Flanders, born about 1300, killed in a popular insurrection, July 17, 1345. He was of noble family, but caused himself to be enrolled in the guild of brewers as a means of gaining the favor of the people. By the generous use of his great wealth, and by his sympathy with the popular cause, he soon acquired a wide influence, was chosen leader of many other guilds besides his own, and won the universal confidence of the people. War was at this time raging between England and France. Count Louis I. of Flanders and nearly all the Flemish nobility were openly on the side of the latter, while the sympathies of the people of Ghent and the great Flemish commercial cities were entirely with the English. Count Louis had made himself most unpopular with his subjects by his tyrannous acts, while Artevelde had attained such power that he acted with entire independence of his sovereign. Thus, when a crisis was brought about by a message from Edward III. of England to the Flemings, asking their alliance, Artevelde took it upon himself to make a treaty with him, in which he was sustained by the citizens of Ghent. Aided by the English, the popular leader forced Bruges and Ypres to join in his treaty with Edward, compelled the count to retire into France, and was himself proclaimed leader or governor (*ruwaert*). He now assumed complete control of Flanders, removed the officials appointed by Count Louis, and when in 1338 the latter returned to Ghent to seek a reconciliation with the citizens, he made him prisoner, and forced him (December, 1339) to agree to the English alliance. Soon afterward Count Louis again returned to France. Artevelde retained almost absolute power in Flanders for nine years, until, by an injudicious project for proclaiming the prince of Wales (the Black Prince) governor of the country, he lost the popular confidence. Feuds followed between the different guilds, which he no longer controlled; the chief of the weavers, Gerard Denys, aspired to be his rival; and finally a battle was fought in the market place, between the weavers and other guilds, in which the former were victorious. Artevelde now thought himself in danger, and introduced a body of English troops into his house; this enraged the people, who rose against him and killed him in his own dwelling. II. **Philip van**, son of the preceding, and like him a popular leader and governor, born about 1340, died in battle, Nov. 27, 1382. During his youth he took no part in public affairs; but when the citizens of Ghent revolted against Louis II., the son and successor of his father's enemy, his name and associations brought him into immediate prominence, and he was chosen ruwaert in 1381. One of his first acts was to bring to execution twelve of those who had assisted in

the murder of his father. Count Louis had in the mean time succeeded in so completely cutting off supplies from Ghent that he had reduced the city to great want. But the citizens endured the suffering bravely, two who proposed surrender being put to death, and Artevelde resolved upon a sally against the count, who had his headquarters at Bruges. With 6,000 troops he encountered Louis near that city, defeated him with great slaughter, and took and plundered the city; upon this victory, the other Flemish towns, except Oudenarde, which he unsuccessfully besieged, submitted. The French king, Charles VI., now sent an army to the assistance of Count Louis. It entered Flanders in November, 1382, and on the 27th met and routed the troops of Artevelde, killing an immense number. Artevelde's body was found among the dead, and hung by the victors to a tree.

ARTHRITIS (Gr. *ἀρθρίτις*, belonging to the joints, from *ἄρθρον*, a joint), inflammation of the joints, of which there are three kinds, traumatic arthritis, rheumatic arthritis, and gouty inflammation of the joints. For the two latter varieties, see GOUT, and RHEUMATISM. Traumatic arthritis is a frequent complication arising from wounds or bruises, contusions, and surgical operations in or near the articulations. Acute inflammation of the articulation sometimes occurs also, without external cause, from the absorption of pus or morbid matter within the system. Women suffering from recent childbirth, or persons afflicted with phlebitis, blennorrhagia, or purulent infection, are liable to suffer from arthritis. Blows, falls, sprains, violent distortion of a joint, fractures, and wounds made by sharp instruments, may all produce acute inflammation of the joints. All the parts of the joint may be involved, or some of the external or internal tissues only; for the intensity of the inflammation is much greater when the capsule of the joint is lacerated and admits the air. During the first day or two the case may seem very simple and without danger to the patient; but often on the third or the fourth day, or even later, the symptoms become more severe, and the pain excessive. Traumatic arthritis is sometimes so severe as to derange the general health profoundly, causing delirium and convulsions; the skin is burning hot, the tongue is red, bile is vomited, and the patient suffers much from bodily pain and mental anxiety. Suppuration is the usual termination of this kind of inflammation. When traumatic arthritis is superficial, it is easily cured; but when deeply seated and admitting air into the joint, it is a serious disease. The proper treatment consists of cloths and compresses steeped in cold water, and placed around the inflamed parts; rest for the whole body, and particularly for the implicated limb; cooling diet, with appropriate sedatives and other medicines. Cupping and leeching are sometimes useful; and where suppuration has commenced, it is commonly more

prudent to allow it to form its own opening for evacuation.

ARTHUR, a hero of British mythology, believed by many to have been identical with an actual sovereign in England in the 6th century. Nennius, the most ancient Cymric poetry, the Triads, and the Welsh bards Llywarch, Ilen, and Taliesin, mention Arthur, a chief of the Britons, fighting against the Saxons under Cerdic. Based upon their statements, many attempts have been made to prove the actual existence of a great sovereign corresponding with the Arthur of romance. It seems probable that a prince called Arthur ruled in Britain about 525, fought many battles with the Saxons, was killed by his nephew, and buried at Glastonbury, where his tomb is said to have been found in the reign of Henry II. But late authorities (among them George W. Cox, who makes a searching inquiry into the story) may be said to have proved that the Arthur of romance is a purely mythical personage. Mr. Cox points out the resemblance between the legends of Arthur and the myths of other ancient nations, and by the aid of etymology shows that many of these were merely allegories derived from natural phenomena.—The Arthur of the famous legend was the son of Uther Pendragon and Igerne of Cornwall, whom Uther, by the enchantments of the sage Merlin, was enabled to visit in the guise of her husband Gorlois. His high descent was concealed, and he was brought up by a faithful knight, who treated him as his own son until after the death of Uther, when Arthur, going with his foster brother to London, gave evidence there of his royal birth by drawing from the stone in which it was imbedded a sword with this inscription: "Whoso pulleth this sword out of this stone . . . is rightwise born king of all England." He was crowned, and after reigning for several years he married Guinevere, "the fairest woman in the land." With her, as a part of her dowry, he acquired the enchanted round table which had once belonged to his father Uther. About this he formed the famous circle of knights of the round table, and with these began the brilliant court, the wonderful series of exploits at home and abroad, and the countless adventures of various heroes, celebrated in the legends preserved in the Chronicles of Geoffrey of Monmouth and elsewhere. The story of Arthur ends with the wound given him by his false nephew Modred, at a battle near Salisbury; after which the king was borne away by the fairies to be cured by them in the valley of Avalon, whence, said the legend, he should some time come again to lead the British Celts against the Saxons.—The legends of Arthur and his knights have been the subject of numberless poems in almost every modern language. Tennyson, more than all others, has added by his "Idyls of the King," "Morte d'Arthur," and other poems, to the beauty of the legends as we know them. For discussions as

to the actual existence of Arthur, see, for support of the theory, "England under the Anglo-Saxon Kings," translated from the German of Dr. J. M. Lappenberg by B. Thorpe (London, new ed., 1857); for the opposite view, the introduction to Cox's "Popular Romances of the Middle Ages" (London, 1871); for history of the old romances treating of Arthur, the appendix to the "History of the Anglo-Saxons," by Sharon Turner (London, 7th ed., 1852); for a good rendering of the legends themselves, the work of Cox, just cited.

ARTHUR, Timothy Shay, an American author, born near Newburgh, Orange county, N. Y., in 1809. He was about eight years old when his parents removed to Baltimore. He was apprenticed to a trade, was for several years a clerk, and in 1833 visited the west as agent of a banking company. Upon his return to Baltimore he became connected with a newspaper, and began to publish a series of short novels. Since 1841 he has resided in Philadelphia, and for many years edited and published a weekly journal and a monthly magazine. His productions are numerous, consisting chiefly of works of fiction of a domestic character, written with a moral aim, several of them relating especially to the subject of temperance.

ARTHUR, William, an Irish Wesleyan clergyman and author, born in the county of Antrim in 1819. After a thorough classical training and special studies in Italian literature, he entered the Wesleyan theological institution near London, and upon graduating was appointed missionary to India; but after three years of successful labor, being threatened with total blindness, he was obliged to return to England. Subsequently he was appointed secretary of the missionary society of the Wesleyan church, and soon afterward was elected president of the British conference. In 1867 he was chosen principal of the Wesleyan college, Belfast, Ireland. In 1870 he was recalled to England, and made honorary secretary of the missionary society of the Wesleyan church. Apart from many valuable contributions to educational and missionary literature, Mr. Arthur is best known by the following works: "Personal Reminiscences of a Mission to the Mysore," "The Successful Merchant—a Memoir," "The Tongue of Fire," and "State in Transition."

ARTICHOKE, an edible plant of the genus *cynara*, order *compositæ*, resembling a large thistle, known in the south of Europe as early as 1548. *C. scolymus* and its variety *C. hertensis* are the green and globe artichokes of the garden. The portion eaten is the under side of the head before the flower opens. The whole head is removed and boiled, the leaves laid aside, and the bottom eaten, dipped in butter with a little pepper and salt. A sauce made of butter and spices is frequently used. The French sometimes gather the heads when not larger round than a dollar, and eat the lower end of the leaves raw, dipping them in oil, pepper, and vinegar. The globe variety is

generally preferred by gardeners. Artichoke seed should be sown in a gentle hot-bed or warm open border as early in the spring as frost will permit. The plants should be set

Globe Artichoke.

four feet apart each way, in a stony soil, well prepared. They will bear heads the succeeding year. Some gardeners place six plants in a hll, making the hills six feet apart. Artichokes may be raised from sets or shoots, which should be removed and carefully transplanted. As often as heads are removed from a plant, it should be broken down to encourage the growth of new shoots. In autumn all plants should receive a good supply of earth or litter. Stable dung is too heating, and should never be employed. In the spring remove the autumn covering and take away all offsets except two or three of the best. During the first season the young plants of the previous year will produce heads from June to October. In succeeding years they will give heads from May to June or July. To have them the whole season, an annual plantation must be made. The flowers of the artichoke have the property of rennet in curdling milk. The French use the heads of the second crop of artichokes when dried, baked in meat pies with mushrooms. Artichoke heads are sometimes made to grow larger by tying a ligature tightly around the stem three inches below each.—The JERUSALEM ARTICHOKE (*helianthus tuberosus*, order *composite*) is not a true artichoke, but the root

Tuber of Jerusalem Artichoke.

of a species of sunflower. In Italian it is named *girasole*, or sunflower, which in English is corrupted into Jerusalem. In America it is sometimes called Canada potato or Virginia potato. It was well known in England as an edible root about the year 1620, having been brought from

Brazil. The tubers are good for swine and cattle. They are capable of resisting the severest degree of cold when left in the soil the whole winter; being lifted in spring, they form excellent food for stock. The Jerusalem artichoke may be raised in all classes of soil, and when grown in light sands and gravels, swine are allowed to dig the tubers for themselves. It is difficult to eradicate this plant from the soil, and it is seldom entirely removed where once rooted in a rich soil. The tops cured in autumn form an excellent hay, yielding five or six tons per acre. Sandy soil of fair quality is said to yield from 1,200 to 1,500 bushels per acre. They are not quite as nutritious as the potato, containing 72.2 per cent. of water, being about 4 per cent. more than is contained in the potato. Cordage is sometimes made out of the tops, and in the south of Europe a kind of coarse cloth is manufactured from them.

ARTICULATA, the third great division of the animal kingdom in the classification of Cuvier, and by him subdivided into four classes. Other naturalists have added four more, making the following eight classes, of which the first four are those of Cuvier:

1. Annelida, as leeches, earthworms, &c.
2. Crustacea, as crabs, lobsters, prawn, shrimps, &c.
3. Arachnida, as spiders, scorpions, mites, &c.
4. Insecta, as beetles, flies, butterflies, &c.
5. Myriopoda, as centipedes.
6. Cirrhopoda, as barnacles and sea acorns.
7. Rotifera, wheel-shaped animalcules, aquatic.
8. Entozoa—lowest of the worms—parasites upon or within other animals.

Each of these classes will be found treated under its own name. The articulata may properly be ranked, upon the whole, as higher in the animal scale than the mollusca, although, as in this division, some species may be found less highly organized than are some of the radiata, the fourth division of the series; for the articulata possess a high development of the locomotive organs, in which the mollusca are particularly deficient. The nervous system also is so organized that it presents a sufficient characteristic for designating the group; and the name *homogangliata* has been proposed by Prof. Owen as a substitute for that of *articulata*, this having reference only to the external conformation of the body in transverse rings, which may be of the soft skin or integument, or else serve, in the form of a hard shell, as an external skeleton, to which the muscles are attached. This arrangement of the nerves is a chain of knots or ganglia, symmetrically disposed upon a double cord, which passes through the ventral region of the body, and from each ganglion nervous filaments pass off to the different segments of the body. A nervous ring from the anterior pair of ganglia encircles the œsophagus. Filaments connect this with the organs of the senses, and the œsophageal ganglia have hence been regarded as analogous to the brain in the higher orders. They are more and more concentrated as the animal occupies a more elevated position in the division, the members of the body being at the same

time brought into closer connection. The symmetrical arrangement of the nerves suggests that of the members also; and the limbs are found arranged in pairs, in the centipedes each pair proceeding from one of the articulations of the body. In the higher classes, as the crustacea, the same symmetry of pairs of limbs is perceived, and the connection of each pair with a segment of the body, even when the thorax, or body, needing no flexibility for locomotive purposes, has its rings very obscurely defined: The lower groups contain the greater number of articulations or rings, and these are usually soft, upon an elongated body, furnished in most cases with no true limbs. Progressive motion is obtained by the bending of the flexible body in one and another direction, the muscles which effect this occupying a large portion of the body which in other animals is usually devoted more to the organs of nutrition and digestion. These in the articulata are not so elaborate as in the mollusca. The organs for respiration are much more highly organized, particularly in the insecta. In the air-breathing species the blood is aerated by being exposed to the action of the air introduced within the body, the fluid being distributed in cavities or tubes permeable to the air; the former appear to be analogous to lungs. In the articulata is found the greatest diversity of forms and habits of life. The largest animals of the division are the lobsters and crabs of the crustacea; the rest are, for the most part, of small size, many of them so minute as to pass unnoticed in the watery elements in which they abound.

ARTICULATION, a term in anatomy, denoting the various modes of union between the bones of the skeleton. We may class articulations under three general heads, viz., movable joints, immovable joints, and joints of a mixed order, being somewhat movable, without much relative displacement of the contiguous surfaces.

Movable joints are the most complex and various in structure; immovable, the most simple. Movable joints are common in the limbs, and the articulation of the lower jaw with the skull; immovable joints are common in the head and face and lower portion of the trunk; mixed forms of articulation are common in the spinal column and the upper portions of the trunk. The hinge joints of the elbows and the knees, allowing free movements in one plane only, form one order of the movable class; the

ball-and-socket joints of the hip and shoulder, allowing free movements in a circular direction, form a second order of the movable class; and different combinations of these two orders, as seen in the articulations of the lower jaw with the skull, of the hands and feet with the arms and legs at the wrists and the ankles, and also of the bones of the hands and fingers, feet, and toes, form a third order of the movable class. The elbow joint, in fact, is of a compound order, being of the hinge-joint form with reference to the cubital movement of the forearm on the arm, and of the ball-and-socket form with reference to the radial movement of the forearm on the arm, in what are termed the supination and pronation of the hand and arm.—The class of immovable joints may also be subdivided into different orders and varieties. In the sacrum and the pelvis many bones which are distinct at first literally grow together in some subjects, so as to efface all trace of original separation, while in others traces remain visible of former separation. In the cranium and the face there are numerous modes of junction between bones connected by immovable articulation. The most prominent order of this class in the cranium is the serrated suture, the firmness of the union being increased by alternate notches or indentations and projections like the teeth of a saw formed on the edges of the bones, the teeth of the one being adapted to the indentations of the other. In this manner the bones of the skull unite at the top of the head and in the centre of the forehead. In other cases bevelled edges overlap each other, and in this manner the temporal bones are joined to the parietal bones of the skull. Another form of fixed articulation is the ridge-and-groove, a ridge being formed on the edge of one bone and a grooved fissure in another to receive it. By this means the bony part of the septum of the nose is inserted into the floor of the nasal cavity to divide the nostrils, and thus form a double cavity by means of a partition wall.—The mixed class of articulations contains many varieties of adaptation. The mode in which ribs are attached to the spinal column behind and to the sternum in front forms one simple order of the mixed class; the mode in which the vertebrae are connected with each other in the spinal column, another, more complex; and the mode in which the slightly yielding portions of the pelvic articulations are connected, a third and simple order of this class.—The movable articulations, being the most complex in form and structure, will give the best idea of the various elements of an articulation; and the ball-and-socket joint, being the most simple of this kind, will serve the purpose of a simple illustration. In the hip joint we have a kind of ball, or rounded surface, at the head of the thigh bone, which hemispherical surface is capped with a thin layer of cartilage, somewhat elastic in structure, and exceedingly smooth on its external surface. In the bones of the pelvis a socket

1. Lower extremity of the humerus, or bone of the upper arm.
- 2, 3. Upper extremity of the ulna, or bone of the forearm.

trunk. The hinge joints of the elbows and the knees, allowing free movements in one plane only, form one order of the movable class; the

is formed, called the acetabulum, exactly shaped for the reception of this hemispherical head of the thigh bone, and this socket is lined with a thin layer of dense, elastic, and polished car-

tilage, so that in the joint two polished surfaces meet together and allow free movement, with the least possible amount of friction; but to lessen the effect of friction, and facilitate the movements of these surfaces one upon the other, a delicate membrane surrounds the external borders of the articular cartilages, and secretes a viscid fluid which lubricates the surfaces, preventing actual contact and destructive friction of the cartilaginous tissues. This lubricating fluid is technically called synovia, and the secreting membrane the synovial sac or synovial membrane. To prevent the dislocation of the joint, a strong rope of fibrous tissue, very similar in structure to that part of an oyster which cannot easily be removed from the shell, connects the top of the ball with the bottom of the socket, in a somewhat loose but very strongly attached manner. This is termed the round ligament; it is very short and very strong. The outer surfaces of the ball and socket (not in the socket, but outside) are connected by means of a strong ligamentous band of fibrous tissue, loosely connecting the head of the thigh bone with the pelvic bones, on the outer rim of the socket, but strongly attached to the bones themselves, which it binds together firmly, while permitting a considerable freedom of motion or rotation in the joint. In other joints of the movable class the outer ligaments are not always continuous and circular bands as in this case, but take the form of

FIG. 3.—Diagram of a longitudinal section of an articulation. A. Bones. B. Articular cartilage. C. Periosteum. D. E. Synovial membrane.

distinct fibrous ropes, strongly attached to the

bones, and forming strong, flexible bands, as strips of leather nailed to the body and the lid of a box serve as ligaments where there are no hinges. Thin, dense, elastic layers of cartilage cap the articular edges and surfaces of bones in the great majority of joints; strong, fibrous, and flexible ligaments connect the bones externally; and, where the joints are very movable, synovial membranes surround the articulating surfaces, and the synovia which they secrete lubricates the surfaces exposed to contact, friction, and mobility.

ARTIGAS, Jose, a South American general, born at Montevideo, in Uruguay, in 1755, died in Paraguay in 1851 (not, as often stated, about 1826). The son of a wealthy landed proprietor, he led for a time an adventurous life as a *gaucho*, and then served as captain in the light cavalry of the provinces, but on account of some difficulty with the governor passed in 1811 into the service of the junta of Buenos Ayres, then in insurrection against Spain. At the head of a band of gauchos, he defeated the Spaniards in several encounters, and vigorously supported the republican army which besieged the Portuguese troops from Brazil who then occupied Montevideo. Passionate and scheming, he soon acted independently, and finally detached his men from the besieging army; whereupon Posadas, director of the junta, outlawed him and set a price upon his head. But the gauchos flocked to his standard, and Artigas, having defeated the troops sent against him, obliged his enemies to cede to him the whole of Uruguay (1814). He next compelled the Portuguese to abandon their attempt to regain possession of Montevideo, which had surrendered. He now acted as dictator in his native country, and made a vigorous but unsuccessful attempt against Buenos Ayres (1815). After various contests he was twice defeated, in 1819 and 1820, and compelled to flee to Paraguay, where Dr. Francia, the dictator, banished him to Candelaria. Here the former gaucho chief devoted himself to husbandry, and to the care of the sick and needy, and attained a patriarchal age.

ARTILLERY, the cannon employed in war, and the troops organized to use them. The Chinese as early as A. D. 969; under the emperor Tai-tsu, tied rockets to their arrows to propel them to greater distances, as well as for incendiary purposes. During the first half of the 13th century all the resources of their military art became known to the Arabs through the Mongol conquerors of China. The idea of the application of gunpowder to projectiles, though said to have been accidentally suggested to Berthold Schwarz about 1330, is probably due to the Moors or Arabs of northern Africa, who had artillery at Cordova as early as 1280. The Spaniards learned its use from them, Ferdinand IV. of Castile taking Gibraltar with cannon in 1309, and guns being employed soon after at the sieges of Baza, Martos, and Alicante. A knowledge ofartil-

lery soon extended throughout Europe, the French having cannon at the siege of Puy Guillaume in 1338, and the English three small guns at the battle of Crécy in 1346. Cannon

FIG. 1.—Early English Cannon, time of Battle of Crécy.

are not referred to in the Hindoo books before the beginning of the 13th century; but during the next hundred years their use became general throughout India, and upon the landing of the Portuguese in 1498 they found the natives their equals in the construction and use of fire-arms.—The European as well as the Asiatic cannon of the 14th century were made of longitudinal bars of iron bound together by hoops, being shaped externally and internally like an apothecary's mortar; they were called bombard,

FIG. 2.—Bombard.

vases, or mortars, were very heavy, and projected stone balls at high angles, doing but little execution; when put in position they were

FIG. 3.—Mortar.

fired from a timber stock or framework, gun carriages being unknown. These unwieldy machines, some of which were breech-loaders, were used not only in siege operations, but in the field and even on shipboard. To give a more accurate direction to the projectile, the bore was afterward made cylindrical and terminated in a very narrow and deep chamber, the object being to increase the effect of the powder by retarding the escape of the gas before it acted upon the ball. During the first half of the 15th century bombards were improved upon and made very large; in France one weighed 10,000 lbs. with a 400-lb. projectile, a second 36,000 lbs. with a projectile of 900

lbs.; they were generally made of several pieces screwed together, and could not be moved unless taken apart. Mortars only differed from bombards in length, but were very rare. The other cannon of the day were *veuglaires*, breech-loaders of less size and power than bombards; *crappeauteaux*, still smaller, weighing from 100 to 150 lbs.; and *culverins*, the smallest of all, unchambered and using projectiles of lead. To facilitate pointing and firing, two or more of the smaller guns were occasionally mounted on a two-wheeled wagon, the whole being called a *ribaudequin*, or organ gun, the earliest form of the modern mitrailleuse. Artillery was very much used during the French war of independence against the English. At the defence of Orleans in 1428 Joan of Arc herself pointed the guns; and as the struggle went on the brothers Jean and Gaspard Bureau became very successful in the conduct of siege operations, being the first to make regular approaches and place guns in breaching batteries under cover of casks filled with earth, instead of merely hiding them behind wooden screens. The marked progress made by artillery had the effect of everywhere increasing the power of the crown at the expense of the feudal nobility, whose castles were no longer able to defy the sovereign. The French were far in advance of their contemporaries, Charles VII. being able to retake in one year all the strong places held by the English. On the other hand, as late as 1453 Constantinople had to be taken by assault, the guns of Mohammed II. being powerless to breach the walls; while the Greek cannon, firing 150-lb. stone balls, did less damage to the Turks than to their own defences. In the middle of the 15th century bombards were universally made of separate pieces of forged iron or bronze, and the great number of attempts at a suitable carriage for the smaller guns showed the importance attached to such a mechanism; culverins were frequently imbedded in stocks which could be raised or lowered to change the inclination, a few having small side projections, the forerunners of trunnions, to prevent lateral rotation.—We have now come to one of the most important eras in the history of artillery, the striking improvements made by the French in the reign of Louis XI., 1461-'83. Having invented trunnions of sufficient strength to stand the recoil, they had an axis about which the gun could turn with ease and be elevated or depressed at will; this great difficulty overcome, they readily devised a carriage at once suited for the transportation and service of the piece, while their progress in metallurgy enabled them to substitute cast-iron for stone balls. The iron projectiles, by their greater density, increasing the tension of the gas so as to endanger the guns in use, they were forced to do away with them and introduce brass pieces of smaller calibre and increased thickness of metal, called cannons, culverins or serpentes, and falcons. The last were the smallest, and fired leaden projectiles instead of

cast-iron balls. The culverin, though of less calibre than the cannon, was a much larger gun, and differed entirely from the culverin of the preceding century. Artillery had hitherto been employed in attacking cities and castles alone, but the perfection to which it had been brought in France made it very formidable in the field also. The rapid conquest of Italy by Charles VIII., the successor of Louis XI., was entirely due to his improved artillery; the French guns, mounted on the new carriages, well horsed, and ready to go into battery at any moment, presenting a marked contrast to the cumbersome Italian bombardiers, firing stone balls, and dragged with great difficulty by bullocks.—During the 16th century brass guns and cast-iron projectiles were adopted throughout Europe, while Tartaglia in Italy made great improvements in gunnery, and invented the gunner's quadrant. The carriages, however, had no limbers and were still heavy and awkward; and as the principal dimensions only were fixed, great differences existed even in those for guns of the same calibre. The cannon belonging to an army, together with the wagons loaded with implements and ammunition, were collected into an artillery train, to which certain officers and artillerymen were attached. The latter were looked upon as mechanics, served a regular apprenticeship, and had a guild of their own; they were divided into cannoners, who served the guns, and artificers, who conducted vertical fire and made up warlike stores. When a war broke out, the different monarchs hired as many as they required or could get, their pay being four times that of a soldier. In battle, artillery tactics consisted in the single detail of putting the guns in position, generally in front of the line, taking care to hide them as much as possible behind troops until they were to open fire. In case of disaster they nearly always fell into the enemy's hands, from its being so difficult to move them. The German, Spanish, and Italian cannon of that age were of sizes and calibres innumerable. Charles V. had more than 50 different kinds, from 12-l-pdrs. down, and found this such a disadvantage, particularly in the field, that he attempted, though ineffectually, to limit their number to eight, including mortars. About the year 1550 the French calibres, which had run all the way from 80-pdrs. down to 1-pdrs., were reduced to six, viz.: cannons, three sizes of culverins, falcons, and falconets; there were no mortars. During the last half of the century case shot (*Hagelkugel*) was invented in Germany, but was not brought into general use; about the same time shells were successfully fired from mortars in that country, the result being kept a profound secret. These projectiles, originally made by fastening together two hollow metal hemispheres, and known to the Chinese and Arabs, were first introduced into Europe by the Italians. In Holland, mortar shells and hand grenades were first rendered useful and effective during the early part of the

17th century, and Maurice and Henry Frederick of Nassau made many artillery improvements, doing away with the arbitrary distinctions between cannons and culverins, based upon their lengths, and restricting the calibres to 48, 24, 12, and 6-pdrs., called cannons, half cannons, quarter cannons, and falcons, the last two being proportionally longer and heavier to prevent damage to embrasures. The dimensions of these pieces were fixed, while handles and cascales, shaped for the attachment of ropes, facilitated mechanical manoeuvres. The gun carriages, which had limbers and ammunition chests, were similarly reduced to four, and their dimensions made so uniform that wheels and other parts were interchangeable.—About the same time Gustavus Adolphus, perceiving the advantages that would result from guns capable of quick motion and rapid fire, introduced light pieces made of thin copper and wrapped about with rope and leather; these, not proving durable, were replaced by iron 4-pdrs. weighing about 650 lbs., and drawn by a single pair of horses. Rapidity of fire was attained by the use of cartridges, the slow process of inserting the powder by ladefuls being thus gotten rid of. Two of these guns were attached to each regiment, and were at first intended to fire canister, before that time only used in siege operations and by ships of war; but they soon came to fire solid shot, and did great execution at the battle of Leipsic in 1631. Gustavus did much also toward developing the tactical powers of the arm by massing the heavy guns in strong batteries on the wings and centre, and doing away with the old fashion of stringing them out in front of the line of battle. He had great confidence in his artillery, which was very strong in proportion to the other arms, there being 80 pieces in 1630 to 20,000 men, and 200 pieces before Frankfort to only 18,000.—Malthus, a nobleman who had served in the Low Countries, introduced the mortar shell into France, where it was first used in 1634. Mortars of 10, 12, and 14-inch calibre were cast under his direction, and about this time came into general use throughout Europe. The shell after being inserted

FIG. 4.—Coehorn Mortar.

was kept in place by a tamping of earth, and its fuse was lighted by hand before the mortar was fired. The small mortar which still bears the name of its inventor Coehorn, an officer in the service of the prince of Orange, was first used in 1674. The invention of howitzers was another signal service which the Dutch rendered to the art of war, the idea having first occurred to them that shells might be used in cannon by shortening the pieces so that the projectile could be inserted by hand.

Howitzers were soon adopted and improved upon by the English; like the early mortars, they were at first discharged by applying fire both to shell and charge. Light pieces called *pierrières*, firing stone balls weighing from 12 to 48 lbs., were still used in some of the European services.—In France, toward the end of this century, artillery matériel was modified and improved, much attention being paid to the character of the gun metal, to the form of the chamber, and to the proper length and weight of the piece. The calibres were restricted to 33, 24, 16, 12, 8, and 4-pdrs., most of which have been retained to this day among their smooth-bore guns; the ammunition consisted of grape and canister as well as of solid shot. Gun carriages were also changed for the better and provided with limbers, while trains of wagons or carts were organized for carrying ammunition; some of the field carriages were made of wrought iron. Louis XIV. was the first sovereign to create a special artillery force; he raised in 1671 a regiment for artillery duty only, and in 1690 founded the first artillery schools. To his age belong also the important inventions of the elevating screw, the prolonge, and the priming tube filled with powder, the old method being to work powder into the vent.—During the first part of the 18th century artillery was generally recognized as an arm, had its regularly incorporated troops, and in consequence made very marked progress. In the campaigns of Marlborough large numbers of guns were used on both sides, and sometimes handled with judgment and skill; at Blenheim artillery, massed on the right so as to enfilade the French position, contributed materially to the victory; and at Malplaquet the English put forward 40 pieces in the centre, while the French guns did not cease firing until the intrenchments were assaulted; only eight or ten were taken notwithstanding this persistence, showing that greater mobility had been attained. In 1732 Vallière made important changes in the French artillery, doing away with the 33-pdr. as too heavy, and giving uniformity to the five remaining calibres as well as to the mortars. In 1747 the French began to fire howitzers in siege operations without first igniting the shell, it having been found that the flash from the charge would light the fuse if there was no tamping. The gun carriages and ammunition wagons were still of various patterns, each arsenal having its own way of constructing them; the axletrees were of wood, and the limbers very low, with horses attached in single file. After the seven years' war position guns began to be permanently assigned to brigades in 5 or 10-gun batteries. In Prussia, Frederick the Great introduced short, light regimental guns, 12, 6, and 3-pdrs., whose weight was but from 80 to 150 times that of the shot; his example was followed by Austria and other countries. He also made extensive use of howitzers firing 15, 20, and 50-lb. shell, which were afterward united in separate batteries. At the end of the seven

years' war the Prussian artillery was in a state of great confusion, there being 12 and 6-pdrs. of no less than three different kinds and weights; this was mainly due to the want of a proper chief of artillery, and to the fact that Frederick had looked upon the arm with disfavor. After Rossbach, where it did excellent service, he seems to have gotten over his prejudice, and we are indebted to him for the first formation of horse artillery in 1759: it consisted of a battery of 10 light 6-pdrs., and, though long in a very inefficient condition, and destroyed at Kunersdorf and again at Maxen, was always reorganized. The seven years' war opened the eyes of the Austrians to the importance of the artillery arm, which was carefully reorganized and improved under the direction of Prince Liechtenstein, who was created chief of artillery, with rank and authority in proportion to the importance of his position; this gave their artillery an immense advantage, and assured its constant superiority to that of most of the contemporary powers. The Russians always attached great importance to their artillery. When they entered Germany in 1758 they had 425 guns to 104,000 men, three *Vicornes* or howitzers, with mounted gunners, being attached to each of their dragoon regiments. Artillery in this century consisted of regimental guns attached in pairs to each infantry battalion, of guns of position organized into large batteries, and of siege or garrison guns. The number of guns was usually 4 or 5 to 1,000 men. The regimental guns advanced with their battalions, unlimbering at 500 paces from the enemy and being thence moved forward by hand. The position guns were posted at the most favorable points along the line; occasionally they were able to take a second position, but it was usually impossible to move them in time to decide the result of a battle. The bronze cannon of this age were elaborately ornamented with carvings and with the eiphers and coats of arms of the reigning monarchs, the early custom of giving a special name to each piece being also retained.—We now come to one of the foremost names in modern artillery annals, Gribeauval. This celebrated Frenchman, having served in the Austrian artillery under Prince Liechtenstein during the seven years' war, returned to France with a thorough knowledge of all the improvements suggested by the experiences of that struggle, and was intrusted in 1765 with the reorganization of the French artillery, then in very poor condition. He began by creating a distinct matériel for each service, field, siege, garrison, and sea-coast. His field guns, 12, 8, and 4-pdrs., were 18 calibres long and about 150 times heavier than their projectiles. The charges were reduced from one half to one third the weight of the shot; but, as the windage was also diminished, he was able to make the guns shorter and lighter without sensibly affecting the range. To these were added a 6-inch howitzer, still retaining a small charge,

though proportionally larger than that before used. These pieces were without ornaments, and were cast solid and then bored out, which made their dimensions much more exact than the old hollow-cast cannon; the trunnions were strengthened by rimbases, and copper vent pieces enabled the guns to be rebushed. The horses were hitched in double files, which greatly facilitated the movements of the carriages, and the draught was made easier by iron axletrees, higher limbers, and travelling trunnion holes; the allowance of horses was six to the 12-pdrs. and four to the 8 and 4-pdrs. Fixed ammunition, elevating screws, and tangent scales, together with bricoles and prolonges, facilitated the service and increased the mobility of the piece. Stronger carriages were made for the lighter guns, and uniformity was established in all new constructions by requiring the arsenals to make every part of the carriages, wagons, and limbers after certain fixed dimensions, so that spare parts could be taken into the field exactly corresponding to those in use. An equipment was thus obtained which could be moved and repaired with a facility hitherto unknown. Gribeauval's reforms did not stop at the matériel, the personnel of the French artillery being completely reorganized in 1765 through his efforts. Two guns were still assigned to each infantry battalion, which were served by detachments from a company of artillery attached to each brigade of four regiments. The rest of the field artillery was organized into two or three reserves, each reserve consisting of divisions of eight pieces, to each of which was assigned a company of artillery. Here we have the creation of the artillery unit; the company organization, afterward merged in that of the battery with its horses and drivers, being for the first time inseparably joined to its munitions and guns. Like all military reformers, Gribeauval encountered most determined opposition, the changes he proposed not being permanently adopted till 1774. His system was far superior to any other of its day, and long served as a model to that of other nations, being introduced with but slight modifications into all the European services. Thoroughly tested in the wars of the revolution, the results triumphantly vindicated the abilities and military genius of its originator.—The French introduced horse artillery in 1792, and cut down their divisions to six pieces, eight being found too unwieldy; these divisions received the name of batteries, and were usually composed of five guns and one howitzer. In 1799 they entirely abandoned battalion guns as impairing the mobility of the infantry, one or two batteries attached to each division taking their places. An artillery train or corps of drivers, composed of enlisted men, was organized Jan. 3, 1800, and distributed among the French batteries, together with a proper complement of horses bought for the purpose; they had previously depended upon civilian drivers hired with their

teams by contractors, the result being that the men, horses, and harness were always in bad condition. No changes in matériel took place under the empire, with the exception of the admission of 6 and 3-pdrs. into the service on account of the immense number of captured guns of these calibres. The tactical combinations of the arm, however, though at first without any essential change, were always brilliant; at Marengo the two batteries of Boudet's division kept the Austrians in check until reinforcements came up and materially assisted in gaining that brilliant victory. The use of artillery in mass dates from the French camp at Boulogne in 1805, where this great tactical improvement was conceived and taught, the first instance of its employment being at Friedland, June 14, 1807. In this battle Gen. de Sémarmont, chief of artillery of the French first corps, combined the divisional batteries into two masses, which suddenly went into action at 600 paces from the Russian left and gradually advanced to within 300 paces, firing with the utmost rapidity; seeing the formidable effect produced, he united both masses into one grand battery of 36 pieces at 150 paces from the enemy, who began to waver under the terrible fire of canister. Upon the Russian cavalry's attempting to charge the grand battery, the general of artillery ordered it to change front and drove them off; the French infantry then advanced and overthrew the enemy. The artillery lost 1 officer, 10 men, and 53 horses killed; 3 officers and 42 men wounded; rounds expended, 2,516, of which 362 were canister. The ground was level and very favorable to artillery fire. The battle of Wagram, July 5-6, 1809, presents another prominent example of the use of artillery masses. Sixty French pieces under Gen. Lauriston, supported by infantry and cavalry, advanced in two columns without opening fire up to canister range of the Austrian centre; only 45 pieces got into position, the others being dismounted by the fire of the enemy's artillery, but these were gradually reinforced by 45 more. The fire of this immense battery, which lasted half an hour, though inflicting great losses, failed to break the Austrians, who repulsed an attack of the French infantry and cavalry; they were however compelled to fall back on account of the turning of their left before the French could reform for a second attack. At Borodino, or on the Moskva, Sept. 7, 1812, and at Lützen, May 2, 1813, the French successfully employed artillery masses for defensive purposes. At the former battle Gen. Sorbier, chief of the French artillery, by uniting 80 pieces, brought the Russians to a stand and finally forced them to retire; at the latter, a battery of 60 guns checked the movement of the allies against the French centre. Further instances of the employment of artillery masses are found in the battles of Ocaña, 1809; Gross-Beeren, 1813; Bautzen, 1813; Hanau, 1813; and Brienne, 1814.—The English artillery about the beginning of the French revolution

horse artillery, however, continued to have drivers specially enlisted for that purpose, and to this very faulty system the mounted batteries have reverted since the Crimean war. In 1827 three field batteries were organized, each having four pieces and 45 horses. The British artillery continued in a very imperfect state up to 1848, a mistaken notion of economy having kept it insufficiently supplied with guns and horses. At that date, as well as in 1852, it was largely increased and placed on a better footing. Each battery now consisted of four guns and two howitzers; the armament being improved by the substitution of 24-pdr. and 12-pdr. howitzers for the old 5½-inch howitzer, by the introduction of the 32-pdr. howitzer, and by the practical abandonment of the heavy 6-pdr. and 3-pdr. guns. The ammunition, particularly the shrapnel, was also made more efficient by the adoption of Captain Boxer's fuse. At Sebastopol in 1854 the English siege pieces consisted of 32 and 24-pdr. guns, 10 and 8-inch shell guns, and 13, 10, and 8-inch mortars. To these were joined 68-pdr. guns borrowed from the fleet, then thought of enormous size; some of them were fired as many as 4,000 times, with a charge of 16 lbs. of powder and with great rapidity. The calibres of the French siege cannon did not materially differ from those of their ally.—The artillery improvement of the other European powers was steadily maintained during this generally peaceful era, and the importance of the arm continued to be felt in the few campaigns which took place. In the Polish war of 1831, as well as in the Hungarian campaign of 1849, the Russians embraced every opportunity for the employment of artillery in mass. At Warsaw the concentrated fire of a large number of guns decided the success of their *coup-de-main* and put an end to the resistance of the Poles; the loss in the Russian artillery was however very severe, the killed alone amounting to 40 officers, 400 men, and 800 horses. On the other hand, at Inkerman in 1854 the Russian attack failed on account of the unskilful handling of their artillery masses. The principal large calibres of Russian cast-iron guns at the siege of Sebastopol were 120 (shell), 96, 56, and 49-pdrs. In Belgium the invention (1835) of a new fuse by Gen. Bormann gave case shot an importance and utility hitherto unknown; while iron came into general use throughout Europe for heavy gun carriages.—The systems of field and siege artillery in the United States were chiefly derived from those of France. After the war of 1812 with Great Britain the artillery arm was almost entirely neglected; no field batteries were kept up, and the heaviest gun mounted on the sea-coast in 1820 was a 24-pdr. About 1839 Secretary of War Poinsett caused field batteries to be organized, which, though few in number, were brought to a high state of efficiency and rendered valuable services during the Mexican war (1846-'8), particular-

ly at Buena Vista, Feb. 22, 1847, where they saved the day. The columbiad, a long-chambered piece capable of projecting shot and shell at high angles and with heavy charges, was invented by Col. Bomford and used during the war of 1812; a similar gun (Paixhans), as we have already seen, was afterward introduced with great success in Europe. In 1844 the columbiad was lengthened and made heavier to enable it to stand an increased charge of one sixth of the weight of the solid shot; but not proving strong enough, even with these modifications, in 1858 its use was restricted to shells, a new gun of improved model taking its place. Wrought-iron carriages for heavy guns were about this time introduced into the United States, and great care was taken in the selection and treatment of American iron, some of which is specially adapted to gun fabrication. About 1847 Gen. Rodman developed his now universally adopted theory of initial tension—in other words, of such a disposition of the metal that when the gun is at rest the interior parts are in a state of compression, while the exterior are in a state of tension; this adds greatly to the strength of the metal, the outer layers being thus forced to stand more and the inner layers less than would otherwise be the case when the gun is fired. To practically obtain this result in cast-iron guns, Rodman had them cast on a hollow core and cooled from within by passing a stream of water through them. In 1850 Admiral Dahlgren proposed a new system of cast-iron guns for

FIG. 6.—Dahlgren Gun.

the navy, which upon trial gave very favorable results and was adopted in 1855. His guns (9, 10, and 11-inch) were made of cast iron, solid, and cooled from the exterior; to obviate the difficulty of strain due to unequal shrinkage, they were cast nearly cylindrical and then turned down to the required shape, thus getting rid of the exterior metal which caused the strain by cooling first in the mould. The chamber is of the Gomer form, the thickness of the metal around the seat of the charge being a little greater than the diameter of the bore; the chase tapers more rapidly than in other cast-iron guns, which makes the breech appear thicker than it really is. In 1837 the calibres of the land service consisted of 10 and 8-inch columbiads, 42, 32, 24, 18, and 12-pdr. guns, 10 and 8-inch and 24-pdr. howitzers, and

13, 10, and 8-inch mortars, all of cast iron. Besides the light 12-pdr. or Napoleon gun,

FIG. 7.—13-inch Mortar.

the bronze pieces consisted of heavy 12 and 6-pdr. guns, and of 32, 24, and 12-pdr. howitz-

FIG. 8.—Field 6-pdr. smooth-bore Bronze Gun.

of Charles VIII.; at Solferino particularly, it destroyed the Austrian batteries at the unprecedented range of 1,600 yards before they could get into position to return the fire, and shook the confidence of the reserves by shelling them at distances hitherto deemed entirely safe. When every gun fired a cast-iron spherical projectile, its weight indicated the diameter of the bore, or calibre of the piece; but with the elongated projectiles of rifled cannon which are of various lengths, the case is very different, the weight of the shot being no indication of the power of the gun, nor giving any definite idea of the size of the bore. With French rifle projectiles whose length does not exceed twice their diameter, the same numbers designate their calibres as of old, but they now refer to kilogrammes instead of pounds; thus the 4-pdr., or four, formerly meant that the gun fired a cast-iron sphere weighing 4 lbs., but now signifies that its projectile weighs about 4 kilogrammes or 8.823 lbs. Compared with English guns of the same diameter of bore, the French throw a lighter shot, the English projectiles, particularly the Whitworth, being always longer. The rifled twelves, consisting of the gun-howitzers (Napoleon guns) converted by rifling, were not used in Italy, there not being enough ammunition, but were successfully tested in Mexico; at Puebla they were found very useful in breaching masonry. The

ers, together with 12-pdr. mountain howitzers and 24-pdr. Coehorn mortars.—We have now come to the most recent period in the history of artillery improvement, extending from the Italian campaign of 1859 to the present date (1873). Although the employment of rifle cannon in war was originally attempted by the English, the French are entitled to the credit of first successfully using them in battle. The English 68-pdr. and 8-inch Lancaster rifles failed at Sebastopol in 1854, the shot jamming in the bores; but the French bronze rifled fours, after a model devised by Col. Treuille de Beaulieu, were brilliantly successful in the Italian campaign of 1859. So recent was their construction that the batteries had to march with empty carriages, the guns being boxed up and sent to the army after it had left France. Once in Italy, the incontestable superiority of the French artillery seemed to recall the days

French also transformed by rifling the old 12-pdr. field gun into a gun of reserve and position, the old long 12-pdr. gun into a garrison gun, and the short 24-pdr. gun and 50-pdr. gun into siege guns. None of these pieces fire solid shot; the three kinds of twelves use the same projectiles, but with different charges of powder. The short twenty-four weighs 2,000 kilogrammes or two tons, and the charge is varied according to the range desired, up to a maximum of $2\frac{1}{2}$ kilos (5½ lbs.), which gives a range of 5,000 metres; the carriage of the gun enables it to be fired as a mortar. The long twenty-four only differs from the short by its length and weight, which is three quarters of a ton (740 kilos) more. The fifty is not heavier than the short twenty-four, and is fired with the same charge of powder; its projectile weighs 51 kilos (113 lbs.), with a bursting charge of 3.5 kilos (7 lbs. 13 oz.). Both are mounted on the same carriage, which is drawn by only six horses. Following the same principles, the French artillerists have also utilized some of the old Paixhans guns by rifling and hooping with steel; a gun of this kind of 22 centimetres bore weighs about 14 tons, and throws 170-lb. hollow projectiles to a distance of 6,000 or 7,000 yards. So, too, with their naval guns: the old thirties, originally intended to carry spherical 32-lb. shot with a charge of 11 lbs., after being hooped

and rifled became useful and valuable pieces. Although the French artillery board rejected the breech-loading system as a needless complication for field guns, they were quick to adopt it for heavy ordnance as economizing space, greatly increasing the ease and rapidity of loading, and affording more protection to the cannoners. The principal French naval guns are the 6½-inch, 7½-inch, 9½-inch, and 10½-inch breech-loading rifles, consisting of a core of cast iron with a reinforce of steel hoops made of a double series of steel rings, one over the other, so as to break joints. In the aperture of the bore a female screw of 15 or 16 threads is cut into the metal of the gun, which receives a cylindrical screw or breech plug, mounted in front, with an elastic steel cup or gas check. That time may not be wasted at each discharge by screwing and unscrewing the whole length of the plug, its surface, as well as that of the female screw in the breech, is divided into six equal parts, from three of which the threads are removed; when the breech is to be closed the threaded portions of the plug are presented so that they come opposite the smooth parts of the hole, and *vice versa*; the plug or stopper is then pushed in, and a third of a turn with the handle brings the screws of both parts together. No further changes were made in the matériel of the field batteries before the war with Prussia in 1870, where the French guns for the first time in history were found far inferior to those of their opponents in range, accuracy, and power of execution, the weakest points about them being the want of flatness in the trajectory and the rapidity with which enlargements and lodgments occurred in the soft metal of the bore. Their projectiles, too, were not effective, many bursting in the air or burying themselves in the ground without producing any effect, while the German percussion shells almost invariably exploded on touching the object. The striking superiority of the Prussian batteries with the Krupp breech-loaders was freely admitted by the French, and had a most important bearing upon the issue of the war. In this struggle the *mitrailleuse* or machine gun was introduced and extensively used by the French, in batteries of ten pieces each, and with most destructive effects. The weapon is on the same general principle as the Montigny mitrailleuse, which has 37 barrels fitted and soldered into a wrought-iron tube, with a movable breech piece worked by a lever, and so arranged that the barrels can be fired simultaneously or at any interval, reloading taking five seconds, and ten discharges per minute being maintained if necessary. The Gatling mitrailleuse, adopted by the United States several years previously, has not been actually employed in war. Several hundred new bronze breech-loading sevens were made in Paris during the siege and used with effect, and great attention has been paid since the war to the reorganization of the French batteries, it being intended to suppress the old

muzzle-loading guns as soon as a definite breech-loading system can be determined upon.—The regimental organization of artillery, which has been always maintained by the French and other great European powers, was abolished in England in 1859, brigades of horse, field, and garrison artillery taking its place; each brigade consists of eight batteries, the terms troop and company being done away with. In 1862 the royal artillery was consolidated with that of the Indian army, the artillery establishment being then divided into 5 horse artillery brigades and 25 field and garrison brigades; it now consists of 6 horse, 8 field, 14 garrison, and 3 mixed brigades of field and garrison artillery; to these must be added one depot and one coast brigade. The Armstrong system was adopted in 1859, after the unsuccessful début of the Lancaster guns in the Crimea, and up to 1864 nearly \$13,000,000 were expended in its development. Experience showed, however, that it was too complicated and would not stand the test of active service; the fermature of the breech-loaders, 40, 20, 12, 9, and 6-pdrs., proved very defective, and the lighter calibres have been lately superseded by muzzle-loading rifles, 7, 9, and 16-pdrs., except in the horse batteries, where a few Armstrong guns are still retained. The heavier calibres, muzzle-loading 600, 300, 150, and 70-pdrs., have been replaced since 1867 by guns of the Frazer system; these new guns are 600, 400, 250, 180, and 115-pdrs., the corresponding calibres being 12, 10, 9, 8, and 7 inches; they are all rifled on the Woolwich system, the twist being uniform in the 7-inch, but increasing in the higher calibres; a 700-pdr. of 35 tons has been recently made, its calibre being 11½ inches. The 64-pdr. muzzle-loading rifled gun is of various constructions, Armstrong, Frazer, and Palliser converted cast-iron, the last being rather heavier than the others. All the heavy guns fire the Palliser chilled shot, cast-iron projectiles with gun-metal studs, except in those common to the various 64-pdrs., which have copper studs.—During the past 20 years a number of different systems of rifled ordnance have been invented in England, the two most prominent being the Armstrong and Whitworth. Armstrong guns are both muzzle-loaders and breech-loaders, the fermature being only strong enough to apply to the smaller calibres. The latter are made by welding together at the ends wrought-iron tubes, made of spiral cords formed by twisting a square bar around a mandrel and then welding; two additional thicknesses or tubes envelop it in rear of the trunnions to give it more strength, the outer of the same material as the inner, the inner one formed of an iron slab bent into a cylindrical shape and welded at the edges; the breech is closed by a vent piece slipped into a slot and held in its place by a breech screw, which presses against it from behind; the screw is tubular, so that the charge can be passed into the chamber when the vent piece is withdrawn; the

vent is in the breech piece, which can be easily renewed when the former becomes enlarged. In the large muzzle-loading Armstrong guns the barrel or part surrounding the bore is made

Fig. 9.—Armstrong Gun.

of solid steel tempered in oil, which diminishes brittleness and adds to the tenacity; the barrel in rear of the trunnions is enveloped by three layers of wrought-iron tubes, not welded together at the ends, but hooked to each other by a system of shoulders and recesses; the tube around the barrel opposite the seat of the charge is called the breech piece, and is not made of spiral bars like the others, but has its fibres and welds longitudinal so as to resist the recoil of the barrel against the head of the breech plug screwed into the breech piece. The number of grooves in the breech-loaders is 34, and the twist one turn in 9 feet; in the muzzle-loaders the grooves are from 3 to 10, and the twist from one turn in 30 to one turn in 38 calibres. The muzzle-loading Armstrongs were formerly rifled upon the shunt system, in which the grooves are much wider than the buttons on the projectile, except near the bottom of the bore; that part or side of the groove passed over by the projectile in passing down the bore is deep enough to admit the buttons freely, while the other side is so shallow that the ends of the buttons are pressed against it as the projectile comes out, thereby forcing its centre or axis toward the axis of the bore. This system has altogether failed in calibres larger than the 9-inch, and was finally abandoned in 1870 even for small calibres. In 1865 the French soft-metal stud and bearing system of rifling was adopted for large muzzle-loading guns, under the name of the Woolwich system; after seven years' trial it is not found to give general satisfaction, and will probably be changed. The Frazer gun is a modification of the Armstrong; the number of coils being lessened, cheaper iron used for the outer coils, which are shrunk on with the trunnion piece, and the arrangement of shoulders and recesses, to prevent separation of the parts, being improved. Whitworth guns are made of a substance called "homogeneous iron," a species of low steel said to be made by melting short bars of Swedish iron and adding a small amount of carbonaceous matter.

The smaller Whitworth guns are forged solid; the larger built up with coils or hoops, which are forced on by hydraulic pressure, being made with a slight taper and the ends joined by screw threads. The hoops are first cast hollow and then hammered out over a steel mandrel, or rolled out in a machine like that used for forming wheel tire; before receiving their final finish, they are subjected to an annealing process for three or four weeks, which, though making the metal very ductile, slightly impairs its tenacity; the breech pin is made with offsets in such a way as to screw into the end of the barrel and the next two surrounding hoops, the breech in the larger guns being hooped with a harder and higher steel than that used for the barrel. The cross section of the bores of the Whitworth guns is a hexagon with rounded corners, and the twist is very rapid. The projectiles are very long, those intended for armor punching being made of hardened iron or steel with very thick flat heads to prevent glancing; shells of this kind have no fuse, the bursting charge being ignited by the heat generated by the violent blow of the projectile on the plate; the powder before being inserted is wrapped in one or more thicknesses of flannel, thus interposing a slow conductor between it and the heated metal, and delaying the explosion until the shell has completed its penetration. The principal Whit-

Fig. 10.—Whitworth Gun.

worth guns are the 120, 70, and 12-pdrs. of 6.4, 5, and 2.75 inches diameter respectively, and firing 151, 81, and 12-lb. projectiles.—The Blakely gun combines in its construction the principles of initial tension and varying elasticity, the object being to bring the strength of all the metal of the piece into simultaneous play to resist explosion. The inner tube or barrel is made of low steel, having considerable but not quite enough elasticity; the next tube is made of high steel with less elasticity, and is shrunk on the barrel with just sufficient tension to compensate for the insufficient difference of the elasticity between the two tubes; the outer cast-iron jacket, to which the trunnions are attached, is the least elastic of all, and is put on with only the shrinkage obtained by warming it over a fire. The steel tubes are cast hollow and hammered over steel mandrels, under steam hammers; by this process they are elongated about 130 per cent., and the tenacity of the

metal is increased; all the parts are annealed. Blakely guns are rifled with one-sided grooves, and are fired with expanding projectiles. The principal calibres are the 700, 550, 350, 250, 200, 120, and 100-pdrs., the diameters of the bore varying from 12 inches to 6.4 inches, and the weights of projectiles from 700 to 100 lbs. Palliser's manner of making a gun consists in introducing into a cast-iron gun a hollow cylinder of coiled wrought iron, of such thickness in proportion to its calibre that the residual strain borne by the tube has such a relation to the strain it transmits to the surrounding cast iron as is best proportioned to their respective elasticities; and by varying the thickness of the tube, the transmitted strains can be regulated with the greatest nicety. In the larger guns he proposes to use two or more concentric tubes; in the very largest, three tubes, the inner one to be of the softest and most ductile wrought iron, the next of a stronger and harsher quality, and the third of steel for some distance in front of the chamber. Old smooth-bored guns, chiefly 68-pdrs., reamed out and strengthened in this way, have shown remarkable endurance, and have been thus utilized in large numbers. Parsons's plan of conversion consists in introducing a tube with a jacket, both of steel, through the breech of a gun, which is afterward stopped up by screwing in a large casebolt; though stronger than Palliser's method, it is much more expensive. Moncrieff's counterpoise gun carriage is designed to shield heavy guns from direct fire, and enable them to be loaded under cover. Having given satisfactory results upon its trial in 1868, the British propose to use it extensively for coast defence, particularly in low sites where the batteries are but little above the water level. The top carriage rests on a strong bolt connecting two elevators, curved in rear, and with a box between them for the counterpoise, which is rather heavier than the gun. Upon firing the recoil makes the elevators roll backward on the chassis, the gun descending and the counterpoise rising. The weight of the latter gradually checks the motion and brings the piece to rest below the parapet, where a brake holds the elevators down until the loading is completed.—During the past decade the Prussian artillery has taken the foremost place, a consequence in great part of Krupp's excellent system of breech-loading rifled cannon. The Krupp guns are made of cast steel, composed of puddled steel and pure wrought iron, melted in crucibles and then run into large ingots, which are worked under powerful steam hammers; the ferrature consists of a block sliding in a horizontal mortise crossing the bore, which is continued through the gun; the gas check is a steel ring, which by its expansion prevents the escape of the gas. In loading, the breech block is only drawn out far enough to allow the charge and projectile to pass through a hole in its end; an exterior lever working on a hinge starts the block,

which being guided by proper grooves can readily moved in or out. The rifling is polygonal-grooved, the lands being very much narrowed at the breech, which relieves the initial strain

FIG. 11.—Krupp Gun.

due to the forcing of the projectile into the grooves. The various calibres are forged from a single ingot up to the 9-inch, in which the trunnion ring is a separate forging; the larger guns are built up by shrinking successive hoops of steel over a central steel tube, the ferrature in the experimental 14-inch being slightly modified so that the charge and projectile are inserted at the side of the breech instead of through the end. The Krupp projectiles are of cast steel lead-coated, and take the rifling at four raised rings on their surface. The deep grooves cut in the steel to retain the lead reduce the strength of the shells so much that they can only contain very small bursting charges compared with those of other systems; the Armstrong and Whitworth 9-inch shells carrying charges of from 10 to 14 lbs., while that of the Krupp 9-inch is less than 4 lbs. The Krupp cannon sometimes use Gruson's chilled iron projectiles. Krupp sixes and fours, firing 13.8-lb. and 8.5-lb. projectiles respectively, were adopted in the Prussian field artillery in 1864, and gave so much satisfaction that they were exclusively used in the war of 1866 with Austria, although one third of the Prussian batteries were then armed with the old 12-pdr. smooth-bore. In the late war with France the marked superiority of the Prussian field guns was greatly balanced by the skilful manner in which they were handled. The principal battles, from Weissenburg and Forbach to Gravelotte, Beaumont, Sedan, and Metz, as well as the engagements with the French army of the north and second army of the Loire, were to a great extent a series of artillery combats; and both French and Prussians attribute the unprecedented successes of the latter mainly to the artillery, which whenever practicable was employed in mass. At Wörth a grand battery of 96 guns covered the overwhelming attack on MacMahon; near Gravelotte over 300 guns deployed on the road to the right of St. Privat and

forced the French infantry to retire; and at Sedan, the greatest artillery battle of the war, the fire of more than 750 guns repeatedly drove back the French troops, with the enormous loss of 10,000 killed and 20,000 wounded. The heaviest Krupp guns used at the siege of Paris were 6-inch (15-centimetre), weighing about 6,000 lbs. and firing 55 to 60-lb. projectiles; they were opposed to the heaviest French naval guns. As a matter of economy, converted twelves and twenty-fours of bronze and cast iron are temporarily retained in the Prussian service for siege and reserve purposes. The larger Krupp calibres are from 6 to 8, 8 to 9, 9 to 10, 11, 12, and 14 inches, most of them being used in both the land and naval services of Prussia. The 8-inch sea-coast gun (209-lb. projectile) can be used with great effect up to 1,800 yards against ships covered by 4½-inch plates; and within the same range the 9-inch gun (297-lb. projectile) can do very serious injury to 6-inch armor plates; up to 700 yards the 9-inch gun can breach an 8-inch shield, but at greater distances 11-inch guns must be employed, which, with their 495-lb. projectiles, are very effective against the heaviest ironclads at 2,000 yards. But two 14-inch guns have been made; with an 150-lb. charge they fire shells weighing 1,080 lbs., exclusive of a bursting charge of 17 lbs., the weight of the solid shot being 1,212 lbs. The 14-inch, with its carriage and turntable, weighs about 90 tons; the gun alone 112,000 lbs., not quite as much as the American 20-inch Rodman. The English have always deemed steel guns dangerous, which is true so far as large solid steel guns are concerned; the built-up guns of this material have however shown remarkable endurance, but in justice to other systems it should be stated that the Rodman prismatic powder, exclusively used in the Krupp guns, gives extremely low pressures. In a recent competitive trial of endurance, however, between a 9-inch Krupp and a 9-inch Armstrong, both using prismatic powder, the German gun had a decided advantage. To Prussia also belongs the credit of the introduction of the new 8½-inch rifled mortar, the projectile having a bursting charge of 15 lbs., and exploding by a percussion fuse; it was used during the late war at the sieges of Paris, Belfort, and other places, the precision of its fire being very remarkable. Russia adopted in 1859 French bronze rifled fours; these have been given up and replaced by Krupp fours and nines, as well as by bronze breech-loading fours and nines, the bores lined with steel tubes, made at the arsenals so as to utilize the old material. The fours weigh 765 lbs., their projectiles 16 lbs.; the nines 1,382 lbs., and the projectiles 31½ lbs. The Krupp system has been also adopted for heavy guns, some of which are constructed by the government at the Abukoff works near St. Petersburg; the 8 and 9-inch guns were the largest calibres up to 1868, when the 11-inch gun was added.

Russia has also adopted the Prussian rifled mortar; there are two calibres, 8 and 6-inch, weighing 8,624 and 3,360 lbs., with 195 and 90-lb. projectiles, the charges being 19 and 8 lbs. respectively. Immediately after the Italian campaign of 1859 the Austrians put in service field guns very similar to the French fours; later they had rifled guns on the Lenk system, which were fired with gun-cotton instead of powder; finally in 1863 they adopted an entirely new system of muzzle-loading bronze guns, of two calibres, eights and fours, weighing 1,099 and 580 lbs. respectively, with 14½ and 8-lb. projectiles. For mountain service bronze rifled threes are used, weighing only 185 lbs. and firing a 5-lb. projectile. The Krupp system has been adopted for all their heavy guns. Italy and Spain adopted without modification the French system of bronze muzzle-loading rifles, which in the latter country were replaced in 1868 by Krupp field pieces, some bronze breech-loaders being also made. Following the example of France, Spain had her large cast-iron cannon hooped to increase their durability, the results giving great satisfaction. The 8-inch Krupp is now included among her heavy guns, and in Cuba she has in service a great many large American cannon, Parrott rifles and Rodman smooth-bores. Belgium has Krupp fours and sixes with calibres of 3 and 3.5 inches; her heavy guns are on the same system. The Krupp field guns are also used by Turkey, Roumania, and Servia, as well as in China and Japan. Switzerland, after adopting in 1862 rifled muzzle-loaders, exchanged them in 1866 for steel breech-loaders. The Swedish, Dutch, and Danish governments, like the French, construct their large rifles of cast iron hooped with steel; some of them have shown great endurance, a Swedish rifle, it is said, having been fired 1,100 times.—In the United States cast-iron cannon attained an unrivalled degree of perfection. Gen. Rodman's model, which does not ma-

FIG. 12.—Rodman Gun.

terially differ from that of 1858, was adopted in 1860 for all sea-coast cannon; the exterior shape is remarkable for its simplicity and relative lightness, the parts being proportioned with reference to the exact amount and locality of the strain, to the entire neglect of the merely ornamental or traditional. Rodman's method of hollow casting having, in conjunction with

his big-grained powder, obviated the main difficulties in making very large cast-iron cannon, a 15-inch gun weighing 50,000 lbs. was successfully cast in 1860, followed in 1863 by a 20-inch gun weighing 115,000 lbs. and firing a 1,080-lb. solid shot. The Rodman smooth-bores are the 20, 15, 13, 10, and 8-inch, the last two being but temporarily retained in service until replaced by heavier guns; only two 20 and two 13-inch guns have been made for experimental purposes, but they have given favorable results. A large number of 15-inch Rodmans are now in service; the shell weighs 330 lbs., the solid shot from 440 to 425 lbs., the service charge being 100 lbs., which will give an initial velocity of 1,500 feet. The accuracy of the gun at 1,500 yards is as great as that of any rifle; its trajectory within this distance is flatter, and the projectile being round has greater precision in ricochet fire. On the other hand, rifles can project loaded shells of peculiar construction so as to penetrate and then explode in the object; their projectiles do not lose their velocity as soon as those of smooth-bores, so that they are more effective at long ranges; while if made of wrought iron or steel, though far more costly, they have much greater endurance than cast-iron guns. The experimental Rodman cast-iron rifles, 12 and 8-inch, the former having the exterior form of the 15-inch smooth-bore, were found not to possess the requisite strength, and the United States is now (1873) about to experiment upon several other systems of rifled cannon, with a view to the adoption of that found most advantageous. The 20, 15, and 13-inch, and of late the 11-inch, naval guns have the Dahlgren exterior shape, but are cast hollow with the Rodman elliptical chamber. A 3-inch rifle muzzle-loading wrought-iron gun was adopted in 1851; it is made by wrapping boiler plate about an iron bar so as to form a cylindrical mass, which is brought to a welding heat in a furnace, and then passed between rollers to thoroughly unite it; the trunnions are afterward welded on and the piece bored and turned to the proper size and shape, the latter being of the general character of the Rodman pattern. Its weight is 820 lbs., that of the projectile being only 10 lbs., in which respect it does not compare favorably with the Prussian, Russian, and Austrian fours, which fire a much heavier projectile in proportion to the weight of the piece. The $4\frac{1}{2}$ -inch rifle is similar in shape to the 3-inch, and was adopted about the same time: it is of cast iron cooled from the exterior, its weight being 3,450 lbs., that of the projectile 30 lbs., while the Russian nine, which only weighs 1,382 lbs., fires a 31-lb. projectile. Though intended for siege and garrison purposes, it has been used with an army in the field in spite of its want of mobility. The Parrott muzzle-loading rifles are cast-iron pieces of ordinary dimensions, strengthened by shrinking a wrought-iron hoop or barrel over that portion of the reinforce which surrounds the charge; the cast-iron body in the larger cali-

bres is hollow-cast on the Rodman plan; the barrel is shrunk on by the aid of heat, the cast iron being prevented from expanding by a stream of cold water made to run through the bore. Parrott guns consist of 300, 200, 100, 30, 20, and 10-pdrs., the diameter of the bores being respectively 10, 8, 6.4, 4.2, 3.67, and 3 inches, and weights of projectiles 250, 150, 86, 28, 19, and 10 lbs. This system has not been adopted by the United States government, though a great many Parrott rifles were used during the civil war, and a certain number of guns of the larger calibres are still temporarily retained. While some Parrott cannon have shown very great endurance and been largely used in breaching masonry and other siege operations, a number have burst, particularly in the navy, the accidents being mainly ascribed to the breaking and wedging of the projectile in the bore; the inventor, however, now asserts that he has corrected this evil. At the beginning of the war a number of old 42 and 32-pdrs. were rifled on the Parrott system for temporary use, and served with projectiles of

FIG. 13.—Parrott Gun.

twice the weight of the corresponding round shot; the 42-pdrs. only were hooped. The Brooke gun, made and used by the confederates, is very similar to the Parrott in shape and construction, except that the hoop is made of wrought-iron rings not welded together. King's counterpoise gun carriage, recently tried in the United States, was found to excel Moncrieff's in strength and simplicity, while giving equal protection to the piece and cannoneers. The counterpoise, connected with the top carriage by ropes and pulleys, is placed in a well made in the parapet opposite the gun; the chassis slopes considerably to the rear, so as to form an inclined plane for the descent of the piece and top carriage; as the recoil forces them back and down, the counterpoise rises in the well until its weight suffices to bring the piece to rest behind the parapet. The counterpoise being heavier than the gun, the cannoneers have no difficulty in making it run up into battery after throwing the eccentric wheels into gear. An improved form of the ribaudequin or organ gun of the 15th century, temporarily in the United States service, received favorable mention at the siege of Charleston in 1863, under the name of the Requa rifle battery; it consisted of 25 horizontal barrels in an iron frame,

a sliding bar in rear worked by two levers forcing the cartridges into the chambers. Gatling's mitrailleuse or machine gun was adopted just too late to be used in the war. It is composed of six barrels, a hand crank causing them to revolve about a central axis parallel to their bores; as each barrel comes opposite a certain point a self-primed metal-cased cartridge, falling from a hopper, is pushed into the breech by a plunger, where it is exploded by the firing pin. The machinery is simple and not apt to get out of order, and the gun can fire 200 shots a minute with great range and precision. There are two calibres in the United States service, 1-inch and 1½-inch, the former firing, besides the ½-lb. bullet, a cartridge containing 16 smaller projectiles, which at short ranges is highly effective. As the weight of the Gatling gun (1,000 lbs.) is very great compared to that of the charge, there is little or no recoil, and when once pointed it requires hardly any adjustment. It is an admirable arm against night attacks, as

FIG. 14.—Gatling Gun.

well as to sweep flanks of fortifications, bridges, streets, breaches, &c., and is in general use in the United States for the defence of military posts on the Indian frontier. The Gatling gun has been also adopted by England, Russia, Austria, Turkey, and Egypt. The light guns employed by the United States troops during the civil war consisted of 3-inch wrought-iron rifles, 3-inch Parrotts, and 12-pdr. Napoleon guns; the last, though abandoned in Europe, being still retained in the American service. Heavy rifled guns played a very prominent part in siege operations, the reduction of Fort Pulaski demonstrating that at 2,400 yards they can breach the best constructed brick scarp; at Fort Sumter the barbette fire was entirely destroyed and the work badly crippled by 14 Parrott rifles (300, 200, and 100-pdrs.), at ranges varying from 3,428 to 4,290 yards. Vertical fire was largely used also on both sides. In April, 1862, Fort Jackson, Louisiana, was bombarded at from 2,950 to 3,980 yards by 19

13-inch mortars from the mortar flotilla under Admiral Porter; the fire was exceedingly accurate, and at the end of seven days made the place untenable. At the assault after the explosion of the mine at Petersburg, July 30, 1864, 10 10-inch mortars, using case for the first time in America, prevented an annoying confederate battery from firing a single shot. The little 24-pdr. Coehorn mortar proved very useful, particularly at the sieges of Charleston and Petersburg. This war also presents various instances of the employment of artillery masses. At Malvern Hill, July 1, 1862, the repeated assaults of the confederate infantry were handsomely repulsed by a grand battery of more than 150 guns under Gen. Barry, chief of artillery, posted on the heights to the west of the plateau. At Chancellorsville, May 2-3, 1863, after the rout of Howard's corps, the victorious confederates were checked and driven back by 24 pieces in mass hastily collected from different corps; and at the same time another

battery of 38 guns assembled near Fairview under Col. Best, chief of artillery of the 12th corps, did great service in keeping back the enemy. At Gettysburg, July 1-3, 1863, 120 confederate guns under Gen. Pendleton, chief of artillery, opened on the left of the Union army preparatory to an assault. Their fire was, however, too much dispersed; and although Gen. Hunt, chief of artillery, could only bring 80 pieces to reply, he was able to render most efficient assistance to the infantry in repulsing both of their grand columns of attack.—Rapid as the development of artillery has been since 1850, we are still in a period of transition due to the successful introduction of rifled cannon. This condition of change has also necessarily extended

to the science of fortification, which must conform to the offensive capacities of artillery. (See CANNON, GUNNERY, and GUNPOWDER.)

ARTIODACTYLES, a name given by Owen to the even-toed division of the *ungulata* or hoofed, herbivorous animals, including the ruminants or the two-toed animals which chew the cud, like the cow, sheep, antelope, camel, and the fossil anoplotherium, and the omnivorous mammals like the hog. In the opposite division of the *perissodactyles*, there is an odd number of toes: either one, as in the solidungulate horse and hipparion; three or five, as in the multungulate tapir, rhinoceros, and palæotherium; or five, as in the proboscidean elephant and mastodon.

ARTOIS, a former province of northern France, which, with a small portion of Picardy, now forms the department of Pas-de-Calais. It lay principally between Flanders on the N. E. and E. and Picardy on the S. W.; area, about 1,800 sq. m. The land is here almost level, and

the soil is exceedingly fertile, owing to the abundance of streams. Artesian wells receive their name from Artois, where they have been common for many years. (See PAS-DE-CALAIS.) Artois was named from the Atrébates, its original inhabitants. After being subject from the 5th to the 9th century to the Franks, it was made in 863 a part of the dowry of Judith, daughter of Charles the Bald, when she married Baldwin of Flanders, but it was restored to France when Isabella of Hainault married Philip Augustus in 1180. Louis IX. made it a county in 1236, under his brother Robert as count. Artois was henceforth governed by Robert's descendants, male and female; but one of the latter marrying a Flemish prince, the county became part of Flanders until the treaties of the Pyrenees and of Nimeguen (1659 and 1678), when it was again made part of France. Before his accession to the throne (1824) and after his abdication (1830) Charles X. bore the title of count of Artois.

ARTOT, Joseph, a Belgian violinist, born in Brussels in 1815, died in Paris, July 20, 1845. When a mere child, he was able to execute very difficult pieces on the violin. In the conservatoire at Paris, he won at the age 13 the first prize for violin playing. After travelling over Europe with marked success, he associated himself in 1843 with Mme. Damoreau, and they gave concerts in the United States, soon after which he died.

ARUNDEL, Thomas Howard, earl of Arundel and Surrey, an English patron of art, born July 7, 1592, died in Padua, Oct. 4, 1646. Under Elizabeth he enjoyed by courtesy the title of Lord Maltravers. The titles forfeited by the attainer of his father were restored in 1603; he was created earl marshal in 1621, and earl of Norfolk in 1644. He served as privy councillor, lord high steward at the trial of Lord Strafford, envoy to the queen of Bohemia and the states general of the Netherlands, and ambassador extraordinary to the emperor Ferdinand II. He is best remembered by his gallery of statuary, which he commenced during his residence in Italy (1607-'14), and for the collection of which he sent John Evelyn to Rome, and Mr. (afterward Sir) William Petty to Greece and Asia Minor. The English ambassadors at the Hague, Turin, Brussels, and Madrid also aided in its formation. Petty acquired valuable works at Paros, Delos, and Smyrna, particularly the celebrated Parian Chronicle, a long, oblong slab of marble, with important chronological records. The Arundelian collection, when entire, comprised 37 statues, 128 busts, and 250 marbles with inscriptions, exclusive of sarcophagi, altars, and fragments; it included also gems, medals, and other intaglios which Lord Arundel had purchased at Venice from Daniel Nys for £10,000. During the civil war (1642), when he returned to Italy, part of the collection, chiefly the gems, were believed to have been removed by him; while of those confiscated by parliament, a

number were said to have been secured by the Spanish ambassador in London, through the medium of Cromwell, for removal to Spain.— On Lord Arundel's death his personal estate was divided between his eldest son Henry and his second son Sir William, the celebrated Viscount Stafford, who was executed in 1680. His grandson Henry, 6th duke of Norfolk, in 1667 presented the inscribed marbles forming a part of his moiety to the university of Oxford, at the instance of Evelyn and Selden. The statues, chiefly the busts, were in 1755 presented to the university of Oxford by the countess dowager of Pomfret, into whose possession they had passed. Other works of the Arundel collection were scattered; some went to Chiswick House, others to Beaconsfield, to Fawley Court, to the Norfolk seat at Worksop Manor, &c. The divorced duchess of Norfolk, by whom the busts and statues were sold, was also the owner of the cameos and intaglios, which finally passed to the duke of Marlborough and are known as the Marlborough gems. Lord Arundel's favorite bronze head of Homer, which is introduced into his portrait by Vandyke, was purchased by Lord Exeter and presented by him to the British museum. The greater part of the Greek inscriptions in the Arundel collection at Oxford were, according to Gassendi, discovered by Peiresc at Smyrna previous to their having been secured by Petty. They were increased by Selden's private collection and other contributions to 150 inscribed marbles of various descriptions. It is proposed to remove both the Arundel and Pomfret marbles from the rooms beneath the Bodleian library, where they now are (1873), to the new Oxford museum. The Parian Chronicle was executed at Paros about 263 B. C., and contains chronological records from 1582 to 264 B. C. Celebrated among Lady Pomfret's contributions to the collection are a colossal torso of a Minerva, and several statues of Roman senators, including one supposed to represent Cicero. At the suggestion of Sir Richard Cotton, and in concert with two eminent scholars, Selden published *Marmora Arundeliana* (1628). An edition by Prideaux of the whole set of inscriptions, issued in 1676 under the title of *Marmora Oxoniensia, ex Arundelianis, Seldenianis, &c.*, was republished with additional comments by Mattaire in 1732. In 1763 a new and splendid edition was published under the auspices of Dr. Chandler of Magdalen college, including ancient inscriptions collected by various learned travellers and engravings of 167 marbles, 103 of which belonged to the Pomfret donation. Among the other valued authorities on the subject is Böckh's *Corpus Inscriptionum Græcarum*.— The Arundel society in London, for the multiplication of fine chromotint copies of remarkable monuments of the old masters, was founded in 1849, and has given a wide and cheap circulation to works of art which had been previously accessible only to the rich.

ARUNDELIAN MARBLES. See ARUNDEL, THOMAS HOWARD.

ARUNDELL, Blanch, daughter of the earl of Worcester, and wife of Lord Thomas Arundell, died in 1649, aged 66. With only 25 men she for nine days defended Wardour castle against 1,300 of the parliamentary troops, and finally made an honorable surrender, the conditions of which were broken by the victors. Her tomb is in the chapel of the castle.

ARWIDSSON, Adolf Ivar, a Swedish poet, born at Padasjoki in Finland, Aug. 7, 1791, died at Viborg, June 21, 1858. He was instructed in history at the university of Abo, where he founded in 1821 the *Abo Morgonblad*, a literary and political journal. This enterprise was unsuccessful, as the Russian government suppressed the publication in a few months, on account of its outspoken judgments of the acts of the authorities. Soon after this Arwidsson published a political essay in the *Mnemosyne*, which was of such a tone as to lead to his immediate banishment. He went to Sweden, secured a position in the royal library at Stockholm, was made its chief librarian in 1843, and continued in this office till his death. In the last years of his life the Russian decree of banishment against him was annulled, and it was while taking advantage of this to revisit Finland that he died. His principal works are: *Ungdoms Rimfrost* ("The Hoarfrost of Youth," Stockholm, 1832), a collection of poems; an excellent collection of Swedish folk songs under the title *Scenska Fornsånger* ("Ancient Swedish Songs," 3 vols., 1834-'42); *Stockholm förr och nu* ("Stockholm formerly and now," 1837-'40); and a translation of the Icelandic *Eriðhiðs Saga* (2d ed., Stockholm, 1841).

ARYAN RACE AND LANGUAGE. Arya (Sanskrit, *árya*; Zend, *árya*) is a name by which the cultivated race of parts of S. W. Asia (Iran and India) anciently called itself, by way of distinction from the ruder aborigines by whom it was surrounded or among whom it had intruded itself; and the adjective Aryan is now commonly used to designate collectively the principal tongues and races both of the region indicated and of Europe. *Ariana, Iran, Iron*, and other kindred appellations, are derived from it; its own derivation is wholly obscure, and the various conjectures formed respecting it are not worth reporting here. Attempts have been made to trace it also in European use, but they have not been successful. It is, then, strictly applicable only to the Asiatic or Indo-Persian division of the family, and it is so applied by the great majority of German authorities, with many French, English, and others; while the whole family is styled Japhetic, or (oftenest by the Germans) Indo-Germanic, or Indo-European: it is doubtless the unwieldiness of the last two names that has given superior currency of late to Aryan.—The Aryan family of languages is divided into seven principal branches: 1, Germanic or

Teutonic; 2, Slavo-Lithuanic or Letto-Slavic; 3, Celtic; 4, Italic (Latin, &c.); 5, Greek; 6, Iranian or Persian; 7, Sanskrit or Indian. That all the languages mentioned do really form one family together, as common descendants of a single original, is beyond all question: the correspondences which they exhibit, both of material and of structure, are such as admit of no other explanation. The comparative study of languages shows that there may be between any two even unrelated dialects a certain number of resemblances purely accidental; also, that one may borrow from another either single scattering words, or, under the influence of mixture of races or of influence exercised by conquest or by superiority of civilization, whole parts of a vocabulary; but only common descent can account for resemblances that reach even into, and are most conspicuous in, the whole series of numerals, the personal and other pronouns, the words of relationship, and the like; and, yet more, that reach into the apparatus of verb and noun inflection, and of derivation. On the other hand, there is no amount and degree of discordance which may not arise between languages originally one, but long separated and growing apart. The differences between English and Irish and Polish and Hindi are merely greater in amount and degree than between English and Dutch and German, covering up and disguising more effectually the common basis which really underlies the one series as well as the other, and making a more thorough and skilled search necessary to its discovery. By way of specimen of the correspondences of Aryan language, we give below the forms in all the branches of one word out of each class mentioned above:

English,	<i>three,</i>	<i>me,</i>	<i>mother.</i>
Slavic,	<i>tri,</i>	<i>man,</i>	<i>matr.</i>
Lithuanic,	<i>tri,</i>	<i>manen,</i>	<i>matr.</i>
Celtic,	<i>tri,</i>	<i>me,</i>	<i>matuir.</i>
Latin,	<i>tres,</i>	<i>me,</i>	<i>matr.</i>
Greek,	<i>treis,</i>	<i>me,</i>	<i>mātr.</i>
Iranian,	<i>tri,</i>	<i>me,</i>	<i>matr.</i>
Sanskrit,	<i>tri,</i>	<i>ma,</i>	<i>matar.</i>

In verbal conjugation, relics of the original personal endings *mī, tī, sī* in the singular, and *masi, tasi, nti* in the plural, are more or less distinctly traceable in all the branches, especially among the older dialects. It is needless to go further in this illustration: the comparative grammars of Bopp and Schleicher give a complete exhibition of the accordant groundwork and superstructure, phonetic and grammatical, of the whole body of languages included in the family; and a host of less comprehensive works show in like manner the connection of one and another branch with the rest.—It is held by those who have studied Aryan language most successfully, that its entire structure is developed out of monosyllabic elements, usually called roots. These were of two classes: predicative or verbal, indicating action or quality; and demonstrative or pronominal, indicating position or direction. By the combination of these two, especially, were

grammatical forms made and parts of speech distinguished. The addition of pronominal endings to verbal roots made a verbal tense in three numbers (the dual perhaps of later origin than singular and plural, and mostly lost again in the later languages), with three persons in each. The prefix of an "augment" (doubtless a pronominal adverb, meaning "then") made of this a past tense; but this augment-preterite has left only scanty and doubtful relics, except in Indo-Persian and Greek. Another past tense, or perfect, was formed by reduplicating the roots, apparently to signify completed action. This is the original of the Greek and Latin perfects, our ("strong" or irregular) preterite, &c. Futures were made later, with auxiliary verbs; one, from *ī*, "go," apparently passed over into a modal use, as an optative, and was succeeded by another, from *as*, "be." A subjunctive mood, of more doubtful derivation, was added; and an imperative, probably limited at first to the second person. This, along with participles or verbal adjectives (for the development of distinct infinitives, verbal nouns, was probably later), appears to have been the whole primitive structure of the simple verb; a causative conjugation, besides, has had important developments in the derived tongues. The declensional inflection (of nouns, adjectives, and pronouns) distinguished also three numbers, and (including the vocative) eight cases in each number; or, besides the six we know in Latin, an instrumental, denoting *with* or *by*, and a locative, denoting *in*. Into this inflection was introduced further a distinction of sex: first, by the special characterization of a feminine; later, by the additional separation of a neuter (which in general differs from the masculine only in nominative, accusative, and vocative). From the original basis of sex, however, there was a very wide departure even in the primitive period, the system of grammatical gender becoming very complicated and artificial. The declension of pronouns was in many points irregular; there were as yet no relative pronouns, that order having grown later out of the demonstratives or interrogatives. Of the other parts of speech, the adverbs alone were a fully formed class; prepositions were still only adverbial prefixes to verbs; conjunctions were very few, and only the merest connectives, the construction of sentences being of the simplest character; articles did not come into existence till comparatively modern times. Numerals had been produced at least up to a hundred; as to *thousand*, the case is very doubtful. The apparatus of noun and adjective derivation, in both primary and secondary suffixes, was already elaborated in its principal features; conspicuous examples are the endings of comparative and superlative, and of participles.—This primitive structure of Aryan language has been variously modified, reduced, and added to, in the later history of the family; it was most fully and distinctly preserved in

the Sanskrit, which on that account casts most light upon the common history of all; but there are points in which each branch leads the rest. On the whole, the tendency has been toward a reduction of earlier synthetic structure, and a prevalence of analytic methods of expression, by the substitution of prepositions for case-endings, and of auxiliaries for verb inflections, and by the multiplication of relational words. Of all the languages of the family, the English has gone furthest in this direction. Aryan language is called distinctively "inflective" (as is also Semitic, although its inflectiveness is of a very different character). By this is meant that it not merely forms combinations from elements originally independent, reducing one of them to a subordinate position, as "formative element," indicating a modification or relation of the other or radical element; but that it also peculiarly integrates or unifies the combined elements, losing sight of and disguising their separate individuality, and even allowing the radical part to become modified within itself by the addition of the other: thus, Sanskrit *vid*, *veda*, *vaidika*; Greek *λείπω*, *έλιπον*, *λείποντα*; Latin *fūd*, *fūdo*, *fūdus*; English (where the endings have disappeared) *sing*, *sang*, *sung*, *song*. It is matter of dispute among linguists whether such changes are by origin purely phonetic, or symbolically significant: the former appears to be the better opinion.—The unity of Aryan language necessarily implies the former existence of a unitary Aryan people; that is, at some time in the past there must have existed somewhere in the world a single limited community, in whose use the language above described grew up and took shape, and by whose extension and separation it became so widely spread and so diversified as we find it actually to be; but when and where, it is impossible to say with any definiteness. The greatest antiquity we can attain in the history of the family is 3000-2000 B. C., when the Indians and Persians formed together one people. The oldest parts of the Vedas may be as old as 2000 B. C.; of the Avesta, considerably less. We have no trustworthy scale as yet with which to measure chronologically the changes of language; and our opinions of the time of Aryan unity must be governed greatly by our opinions as to the wider question of the antiquity of man; the former is variously estimated at from three up to five or ten thousand years before Christ. As to the place, current opinion is inclined to fix it on the highland of central Asia, near the head waters of the Oxus and Jaxartes; and this situation is claimed to be pointed out by the evidence of the language itself. That, however, is by no means the case; the mere fact that Indo-Persian language is less changed from original Aryan than is the speech of any other branch (which is all the linguistic evidence that can be alleged) does not at all prove that the Indo-Persian common abode is nearest to the original abode of the family; the changes

of language are not dependent on and measured by emigration. It is in reality only the testimony of the Bible as to the place of origin of the whole human race, and the long-rooted opinions which have grown up partly under its influence, partly under that of the known growth and spread of civilization, that have led men to look to southwestern Asia as the cradle of the Aryan race and speech. Some recent scholars, rebelling against these influences, have fixed it rather in Europe; but there is nothing of definite value to say for this view. With reference, however, to the degree of cultivation reached by the Aryan mother tribe before its separation, more definite and trustworthy information is obtainable: by inference, namely, from the words which, as occurring in all or nearly all the branches, must be supposed to have formed a part of the primitive vocabulary. The items of such information were first put together by A. Kuhn; Pictet later produced an elaborate but uncritical and untrustworthy work on the subject; the last attempt at reconstruction of the Aryan vocabulary is by Fick. The main facts established are that the tribe was already far past savagery, having all the principal domestic animals that we have, practising the arts of weaving and agriculture, being acquainted with one or two metals (whether iron is not certain), and possessing some of the most important cereals; it was rather pastoral-agricultural than nomadic in its way of life.—It is, of course, vain to attempt tracing the history of dispersion and migration of the branches of the dismembered family into their present seats; but such dispersion must have taken place mainly by gradual spread and unconscious separation, not by a deliberate parting and marching off in different directions, as some seem to please themselves with fancying. Even the grade of kinship between the branches is not made out beyond dispute. That the Sanskrit-speaking race of India parted from the Iranians, on Iranian territory, and entered India by the northwest, not very long before the Vedic period, is, indeed, universally acknowledged. And the closer relationship of Greek and Italic, on the one hand, and of Germanic and Letto-Slavic, on the other, is quite generally held; but which of these two pairs stands nearer to the Asiatic is a matter of less unanimity of opinion, though with a preponderance to the side of the classic tongues. The place of the Celtic, again, is still more disputed: some connect it closely with the Italic, others rather with the Germanic, &c.; while yet others regard it as quite separate from all. These are matters which will doubtless be determined by and by; and their determination may throw more light than we have at present upon the general course of the movements of the family. There may have been other branches, as independent as the seven mentioned, but driven out of existence in the course of the historical changes that time has brought; it is doubtful

whether the Albanian, or Shkipetar, is not a relic of such a branch, the Illyrian; after long doubt, the best authorities at the present time appear to set it down as Aryan. What other races may have earlier occupied a part of the present seats of the Aryans is also mainly matter for conjecture; but that the latter have encroached upon the domain of Finno-Hungarian ("Turanian") tribes in northern, and of Iberians (Basques) in southwestern Europe, does not admit of question. More or less of mixture with aboriginal races is a natural or unavoidable result of such wide extension; so that Aryan speech is likely to be everywhere purer than Aryan blood; and there may be nations or tribes in which, by successive intermixture, Aryan blood is in a minority, even a decided one; yet it is not at all to be questioned that, on the whole, the present geographical limits of the family have been reached by the growth and spread of the original Aryan community. No hypothesis of borrowing, or of the dominating influence of one tribe, propagating and imposing its own idiom through wide regions, can possibly explain the facts of the case; such influence is absolutely impossible without high culture, aided by literature and the art of writing, of which there are no traces in the pre-historic Aryan period.—One of the evidences that there is a unity of race as well as of language among the branches of the Aryan family, is the eminence, historical or literary, or both, which most of them have won among mankind. The family was far from being the first to rise to importance, but it has reached a higher place, and maintained itself there more persistently, than any other. The Persian empire may be regarded as the earliest appearance of an Aryan people as a leading actor in the drama of history; then Greek and Roman supremacy followed one another; and in the modern era, it is the European nations of this kindred, with their colonies, that have been and are almost monopolizing the progressive force of humanity. India has lived a more isolated life, but a grand and notable one; and, through Buddhism, it has powerfully influenced a great part of Asia. This historical importance of the Aryans constitutes one great source of the importance and interest belonging to the study of their languages. Another is the high rank of those languages themselves, as being confessedly the most perfect instruments of human expression and aids to human thought. Moreover, the immense range and variety of Aryan dialects, taken in connection with their high development and with the legibility of their history, have made the study of this family the training ground and the basis of general linguistic science.—For more detailed discussion of the matters presented here, see the "Lectures on Language" of Professors Max Müller and W. D. Whitney; the second volume of Duncker's *Geschichte des Alterthums*; Pictet's *Origines indo-européennes*; and Fick's *Vergleichendes*

Wörterbuch der Indogermanischen Sprachen. The last two, with Bopp's and Schleicher's comparative grammars, have been mentioned above. The relations of Latin and Greek respectively to the family have been best set forth by Corssen, *Lateinische Sprache*, and G. Curtius, *Griechische Etymologie*.

ARZACHEL, Abraham, a Jewish astronomer, born at Toledo, Spain, flourished about 1060. He wrote a work on the obliquity of the zodiac, and determined the apogee of the sun. The famous Alfonsine astronomical tables, prepared in 1252 by order of Alfonso X. of Castile, were derived in part from the writings of Arzachel. Several of his works are extant in Latin.

ARZAMAS, or **Arsamas**, a town of European Russia, capital of a district, in the government and 60 m. S. of the city of Nizhni Novgorod, on the Tyesha; pop. in 1867, 10,517. It is an old town, and has 34 stone churches, a fine cathedral built in 1812-'41, several convents, manufactures of silk, linen, iron, and leather, and two annual fairs.

AS, a Roman weight, equivalent to the *libra* of 12 ounces. It was also the name of a Roman brass coin, originally an *as* in weight, but reduced at successive times, until it weighed but half an ounce; it was stamped at first with the figure of a sheep, ox, or sow, afterward with the face of Janus, and a ship's prow.

AS, or **Asa** (Norse, plur. *Æsir*; Ger. plur. *Aesen*), in northern mythology, a member of the ruling race of gods, 12 male and 12 female, including Odin, Thor, Baldur, Freyr, Frigga, Freyja, Idunna, Eira, and Saga, who dwelt in Asgard. (See MYTHOLOGY.)

ASA, the third king of Judah, reigned 41 years, about 957-916 B. C. He was the son and successor of Abijam, and great-grandson of Solomon. He distinguished himself by his opposition to the forms of idolatry which had become prevalent in the preceding reigns. Being assailed by Zerah, an Ethiopian king, with an immense army, Asa won a complete victory, and for ten years enjoyed peace. Then he became involved in a war with Baasha, king of Israel, and, at the cost of the accumulated treasures of the temple, induced the king of Damascus to enter into alliance with him. His reign was upon the whole a prosperous one. He was succeeded by his son Jehoshaphat.

ASAFETIDA (also called *stercus diaboli* and *cibus decorum*), a resinous gum derived from the root of the *narthex asafetida*, a plant of the family *umbellifera*, which grows in Persia, Afghanistan, and neighboring regions. It yields all its virtues to alcohol. Triturated with water, it forms a white or pink milky emulsion. Its peculiar property is its strong disagreeable odor and taste. This resides in the volatile oil it contains, which may be separated by distilling the aqueous or alcoholic solution. The oil is said to contain from 15-75 to 23 per cent. of sulphur. Asafetida is used in Persia as a condiment for flavoring sauces and food. The leaves are eaten and the root roasted

for the same purpose. It is used in medicine as an expectorant and antispasmodic or nervous stimulant. It is supposed to act beneficially in

Narthex asafetida.

hysteria, flatulence, and some spasmodic affections of the respiratory organs. (See ANTI-SPASMODICS.) The volatile oil is undoubtedly absorbed, as is shown by the odor being perceptible in the breath and other excretions.

ASAPH, a Levite, appointed by David as leading chorister in the musical services which he organized in connection with divine worship. The duty thus assigned him descended by a certain succession in his family, constituting them a kind of order parallel with the priesthood, though not equal to them in dignity or influence. The "children of Asaph" appear still in the times of Ezra and Nehemiah as holy singers. Asaph is called in Chronicles a seer (*hozeh*), and twelve psalms (l. and lxxiii.-lxxxiii.) are attributed to him. Another Asaph was chancellor of King Hezekiah.

ASBEN, in Africa. See AIR.

ASBESTUS (Gr. *ἀσβεστος*, a substance unaffected by fire, from *ἀ* privative and *σβέννυμι*, to quench), a term used rather to denote a peculiar form assumed by several minerals than to designate any particular species. Tremolite, actinolite, and other forms of hornblende, excepting those containing much alumina, pass into fibrous varieties, the fibres of which are sometimes very long, fine, flexible, and easily separable by the fingers, and look like flax. These kinds, like the corresponding mineral pyroxene, are called asbestus. Pliny supposed it to be a vegetable product, although good for making incombustible cloth, as he states. The *amianthus* of the Greeks and Latins was the same thing; the word meaning undefiled, and alluding to the facility of cleaning the cloth by throwing it into the fire. The colors vary from white to green and wood-brown. The name *amianthus* is now applied usually to the finer and more silky kinds. Mountain leather is a

kind in thin flexible sheets, made of interlaced fibres, and mountain cork the same in thicker pieces; both are so light as to float on water, and they are often hydrous. The individual crystals of asbestos are easily separated from each other, are very flexible and elastic, and have a fine silky lustre. A single fibre fuses into white enamel glass; but in the mass it is capable of resisting ordinary flame, and has hence been extensively applied in the manufacture of fire-proof roofing, flooring, steam packing, clothing, and lamp wicking. The ancients were familiar with its incombustibility, and wove a cloth out of it for the purpose of wrapping up the bodies of the dead when exposed on the funeral pile; they also made napkins of it, which were cleaned by throwing them into the fire; and they employed the finer varieties for the wicking of votive lamps. Gloves for handling hot iron and firemen's clothing have been made of it in Bohemia and France; and at one time it was thought that an important industry would grow out of this application, but experience has developed some practical difficulties, and asbestos fabrics are now a curiosity. The use of this material for a non-conducting envelope of steam pipes, for fire-proof roofing, and for safes, bids fair to become extensive.—Asbestos occurs abundantly in Switzerland, Italy, Scotland, on the island of Corsica, on Staten Island, and in numerous other localities. A magnesian-iron hornblende called anthophyllite frequently occurs as a boulder on the island of New York, and has been found *in situ* at the corner of 59th street and 10th avenue.

ASBURY, Francis, the first bishop of the Methodist Episcopal church ordained in America, born at Handsworth, Staffordshire, England, Aug. 20, 1745, died at Spottsylvania, Va., March 31, 1816. At the age of 14 he was apprenticed to a mechanic; but through the influence of the Methodist preachers who visited his father's house, he was led at the age of 16 to commence his labors as a local preacher. In 1767 he joined the itinerant ministry, and after three years of home service was sent in 1771 as missionary to America, and the next year was appointed by John Wesley general assistant in America. He reinvigorated the itinerant system, and sent missionaries into wide ranges of country to preach and found new societies. On the outbreak of the revolutionary war, many of the clergy of the church of England and some of the Methodist preachers returned to England. Among the latter, in 1778, went T. Rankin, who had succeeded Asbury as general assistant. Asbury resolved to remain in America. In common with many others, he was from conscientious scruples a non-juror. From this cause, and from the effect of Mr. Wesley's "Calm Address, &c.," Asbury and his Methodist coadjutors were regarded with suspicion by the struggling colonists, and often molested in their work; his prudence however at length allayed prejudice. On the return of peace it was

deemed expedient to establish an independent Methodist Episcopal church for America. Accordingly, on Sept. 2, 1784, Thomas Coke was duly ordained by Mr. Wesley and two other English presbyters superintendent of the Methodist societies in America, with instructions to ordain Asbury as joint superintendent. On Dec. 27, 1784, after unanimous election by the American preachers, he was inducted into office. For more than 30 years his personal history is the history of the progress and development of Methodism in America. In middle life he was of robust frame, of medium stature, with a fresh and healthful countenance, and a keen, penetrating eye that told of his wonderful insight into character. Though not privileged with the culture of the university, he had acquired a moderate knowledge of the Greek and Hebrew languages. In connection with Coke, he devised a plan for a complete system of academic and collegiate education, and as early as 1785 laid the foundations for the first Methodist college in America. As an organizer and administrator Asbury was only inferior to Wesley, by whom he had been instructed, and much of whose spirit he had imbibed. During his American ministry he travelled over 270,000 miles through the entire extent of the country; he preached about 16,500 sermons, or nearly one each day for 45 years; he presided at 224 annual conferences, and ordained more than 4,000 preachers. The organization, discipline, and marvellous progress of Methodism were largely due to the sagacity, administrative ability, and untiring activity of Asbury. Through the itinerant system, of which he was the reinvigorator and life-long illustrator, the spiritual destitution of our pioneer population was relieved. He was never married. His only literary works are his "Journals" (3 vols. 8vo), an invaluable record of his remarkable life.

ASCALON (Heb. *Ashkelon*; Arab. *Askalan*), one of the five leading or princely cities of Philistia, was situated midway between Gaza and Ashdod, on the Mediterranean, about 37 m. S. W. of Jerusalem. Though several times mentioned in the poetical books of the Scriptures, it figured less conspicuously in the early history of the Hebrews than in that of the Maccabees and the crusades. It was twice taken by Jonathan the Asmonean, was the scene of a great victory of the Christians under Godfrey and Tancred in 1099, was taken by Baldwin III., king of Jerusalem, in 1153, and was recaptured by Saladin in 1187. By treaty between Richard and Saladin (1192) it was destroyed jointly by the Mussulmans and Christians. The wine of Ascalon is celebrated by Pliny. Near the town stood in antiquity a famous temple of Derceto, the Syrian Venus, of which, however, no trace remains now. Altogether, as Zephaniah predicted, Ascalon has become "a desolation."

ASCARIDES (Gr. *ἀσκαρίς*), a term used by Hippocrates, and now applied to several nematoid

worms which infest the intestines of man and animals: the *ascaris vermicularis*, mawworm or pin worm, which infests the rectum or lowest intestine; the *tricocephalus dispar*, or long thread worm, found in the cæcum or upper part of the large intestines; the *A. lumbricoides*, or large round worm, mostly found in the small intestines. The body of the large round worm is long, elastic, and fusiform, or tapering at the two extremities; the anterior being somewhat obtuse and furnished with three tubercles, which surround the mouth. (See ENTOMOZOA.)

ASCENSION, a S. E. parish of Louisiana, intersected by the Mississippi river and bounded N. E. by the Amite river and E. by Lake Maurepas; area, 420 sq. m.; pop. in 1870, 11,577, of whom 7,310 were colored. The parish consists chiefly of an alluvial plain. A great part of the land is subject to frequent inundations, and is extremely fertile, particularly on the banks of the river. In 1870 the parish produced 160,542 bushels of Indian corn, 981 bales of cotton, 15,926 lbs. of rice, 6,423 hhds. of sugar, and 308,587 gallons of molasses. Capital, Donaldsonville.

ASCENSION DAY, a festival of the Roman Catholic and Episcopal churches, kept in commemoration of the ascension of Jesus, recorded by the evangelist to have happened on the 40th day after his resurrection. It is kept on Thursday, and the day is also called Holy Thursday. It has been observed at least since A. D. 68. In the 5th century Mamertus, bishop of Vienne, instituted a three days' preparation for this festival. This occupies the three days immediately preceding Holy Thursday, which are called rogation days.

ASCENSION ISLAND, an island about 8 m. in length and 6 in width, lying in the south Atlantic ocean, in lat. 7° 56' S., lon. 14° 25' W. It is of volcanic formation, mountainous, and was barren and uninhabited until the imprisonment of Napoleon at St. Helena, when it was occupied by a small British force, who have continued to cultivate and improve it. Its shores supply a vast number of turtles. It serves as a depot and watering place for ships.

ASCH, a town of Bohemia, situated near the frontiers of Saxony and Bavaria, 14 m. N. W. of Eger; pop. in 1869, 9,405. It is the seat of an important industry, especially in silk and woollen goods. Formerly the "dominion of Asch," embracing an area of 41 sq. m., was an immediate territory of the German empire; in 1331 it was made a fief of the Bohemian crown, but received in return a promise of a perpetual exemption from taxes; its entire incorporation with Bohemia did not take place till 1770.

ASCHAFFENBURG, a city of Bavaria, in the circle of Lower Franconia, on the right bank of the river Main, which is here crossed by a handsome stone bridge, 23 m. E. S. E. of Frankfurt; pop. in 1871, 9,212. It has a fine palace, the Johannisburg, formerly the residence of the electors of Mentz. Among the other nota-

ble buildings are the Stiff's Kirche, erected in 980, and the Pompejanum or Pompeian house, which Louis I. built from 1842 to 1849 in imitation of the house of Castor and Pollux at Pompeii. Aschaffenburg was a town as early as the 8th century, and in the middle ages often appears in history. During the war between Prussia and Austria, in 1866, an engagement took place at Aschaffenburg on July 14, in which the Austrians were defeated, and 2,000 of their troops were cut off from retreat and captured in the city.

ASCHAM, Roger, an English scholar, born in Yorkshire in 1515, died Dec. 30, 1568. He was of humble parentage, and was brought up by Sir Anthony Wingfield, with whose sons he was educated. In 1534 he graduated at St. John's college, Oxford, where he gained a fellowship. Ascham early embraced Protestant principles. In 1537 he became a college tutor, and was appointed by the university to read Greek in the public schools. When Henry VIII. founded a Greek lectureship Ascham was appointed to it, and in 1544 was made university orator, a post which obliged him to prepare all addresses and write the complimentary and business letters to great men. For this his elegant Latinity particularly qualified him. In 1548 Ascham was appointed teacher of learned languages to the lady Elizabeth, afterward queen. He continued in her household two years, when he quitted her suddenly from a pique against persons in her establishment. In 1550 he was appointed secretary to Sir Richard Morysine, the English ambassador to the emperor Charles V., which appointment he retained for three years, until the death of Edward VI. and the ambassador's recall. While abroad, he travelled in Germany, visited Italy, and wrote the results of his travels in "A Report and Discourse of the Affaires of Germany." On his return in 1553 he was appointed Latin secretary to the queen, and on the death of Mary he was continued in his office by Elizabeth, who required his services as tutor in the languages, in which he read with her several hours each day. He wrote a small treatise on archery, entitled "Toxophilus," and dedicated it to Henry VIII., who ordered him an annual pension of £10 for it. He also wrote "The Scholemaster," a treatise on the study of languages, which was first published by his widow. His letters to Oxford during his stay abroad were also collected and published. His works were published entire, Oxford, 1703, and his English writings, London, 1815, with a life by Dr. Johnson.

ASCHERSLEBEN, a town of Prussia, in the province of Saxony, about 32 m. S. by W. of Magdeburg, on the river Eine; pop. in 1871, 16,734. It has manufactures of woollen and linen. In the middle ages the counts of Ascania (a district including the present circles of Aschersleben, Ermsleben, and Ballenstedt) resided here, and the ruins of their castle are still in existence on the neighboring Wolfsberg.

ASCIDIANS. See MOLLUSCOIDS.

ASCLEPIADES, called from his native country Bithynus, a physician, born at Prusa in Bithynia in the 2d century B. C., flourished in Rome in the early part of the 1st. He first studied rhetoric and philosophy, but afterward abandoned them for the study of medicine. Though his system contains some rules approved by modern science, such as reliance upon gentle measures, diet, fresh air, &c., he seems to have attained success rather by indulging the whims and caprices of his patients, flattering their prejudices, and caring for their comfort, than by any ability of his own. After successful practice in several Grecian cities, he went to Rome, where he gained great fame and wealth. He is said never to have been ill, and to have died at a great age by an accident. He left several disciples, who attained considerable prominence as teachers of his doctrines.

ASCOLI. I. A city (anc. *Aseulum Picenum*) of central Italy, capital of the province of Ascoli Piceno, on the right bank of the Tronto, 18 m. W. of the Adriatic and 87 m. N. E. of Rome; pop. about 11,000. It is well built, and has a citadel, a Jesuit college, a museum, library, and a number of private palaces. Its harbor, Porto d'Ascoli, at the mouth of the Tronto, is defended by two forts, and is frequented by coasting vessels. **II.** **Ascoli Piceno**, a province of central Italy, formerly belonging to the papal territory, and now constituting one of the four provinces of the Marches; area, 808 sq. m.; pop. in 1872, 203,009. Part of the province is traversed by branches of the Apennines and by numerous valleys watered by the Tenna, Aso, Tesino, Tronto, and other rivers. The chief products are corn, wine, oil, honey, silks, wool, and fish. **III.** **Ascoli di Satriano** (anc. *Aseulum Apulum*), a town of S. Italy, in the province of Capitanata, situated on the E. slope of the Apennines, 65 m. E. N. E. of Naples; pop. about 6,000. Near it Pyrrhus in 279 B. C. gained a great victory over the Romans; and in 1190 Count Andrea, general of the emperor Henry VI., was defeated here by Tancred and slain. The ancient town was on a branch of the Appian way, and considerable remains exist outside the modern town.

ASCOT HEATH, a race course in Berkshire, England, 26 m. from London and 6 m. from Windsor, near the London and Southwestern railway. The annual meeting in June is one of the principal events of the turf. The first prize is a gold cup valued at £500.

ASELLI, or **Asellio**, **Gasparo**, an Italian anatomist, born in Cremona about 1580, died in Milan in 1626. He was professor of anatomy in the university of Pavia. In 1622, while demonstrating the recurrent laryngeal nerves by the dissection of a dog, he first observed the lacteal vessels as a congeries of white cords disseminated through the mesentery; and on opening one of them with the point of the scalpel, the milky chyle flowed out, and the discovery of the absorbent vessels was accom-

plished. Before that period the mesenteric veins were supposed, as in the time of Galen, to collect from the intestines all the nutritious products of digestion and to carry them to the liver, where they were worked up into the perfected blood, and the blood thence disseminated, through the rest of the venous system, outward to the whole body. A part of the blood only, passing to the heart and lungs, was thought to be arterialized, and so sent out through the arteries from the left ventricle, as the venous blood was sent out through the veins. The discovery of Aselli consisted simply in finding a new set of mesenteric vessels which took up from the intestines the chyle alone, and conveyed it toward the central organs. He did not detect their real ultimate course, but supposed them to terminate in the liver, which still remained the supposed organ for the elaboration and perfection of the blood. It was only some years later (see PECQUER) that the independent course of the lacteals and lymphatics was ascertained, passing through the receptaculum chyli and the thoracic duct to the left subclavian vein. Aselli, however, was the pioneer in this discovery, and the subsequent success of others depended on the facts demonstrated by him. They are embodied in his dissertation *De Lactibus sive Lacteis Venis* (Milan, 1627).

ASGILL, John, an English lawyer and writer, born about 1655, died in London in 1738. After acquiring considerable reputation in London in his profession and as a political and legal pamphleteer, he went to Ireland in 1699, where he was elected to the Irish parliament. Before taking his seat, however, he was expelled, Oct. 11, 1703, for blasphemy in his pamphlet on the possibility of avoiding death, "An Argument proving that, according to the Covenant of Eternal Life revealed in the Scriptures, Man may be translated hence into that Eternal Life without passing through Death" (London, 1700), which was publicly burned. Returning to London in 1705, he was elected in 1707 to the English house of commons; but he was also expelled from this for the same cause. He passed the last 30 years of his life in prison for debt, continuing to transact professional business, and publishing numerous pamphlets.

ASH, a name applied to four genera of forest trees. **I.** *Fraxinus* (Gr. *φράξιν*, separation, from the wood being used for fences, or from the facility with which it splits), of the family *oleacea*, Juss., *diavica diandria*, Linn. Polygamous, calyx minute, 3 to 4 cleft; corol deeply 4-parted or none. Stamens 2 to 4; pistillate flowers; ovary superior, compressed, 2-celled, with 2 ovules each; capsule with a membranaceous lanceolate wing (*samara*), 1-seeded by abortion; seed pendulous. Most of the species are indigenous in North America (more than 30 E. of the Mississippi), many in Europe, few in Asia (one in Nepal). Most are large trees, affecting shady and moist places, banks of rivers, or marshes; they prosper less in barren and

bleak localities. The wood of most species is tough and elastic, and is used by wheelwrights, carriage-makers, and ship-builders, for many purposes. The most important species are the following; *F. acuminata* (*Americana*, *discolor*, white ash); leaves pinnatifid, leaflets petiolate, oblong, 3 to 4 pairs and 1 odd one, acuminate, shining, entire or slightly toothed, glaucous beneath, downy when young; grows 60 to 75 feet high. This furnishes the best wood of all. It flourishes from Canada to Carolina, and is believed to be an antidote to snake poison. *F. sambucifolia* (black or water ash); leaves large; leaflets 7 to 9 pairs and 1 odd, sessile, ovate, lanceolate, rounded at base, rugose, shining and smooth above, villous beneath on the veins; 60 to 66 feet high. *F. tomentosa* (*pubescens*, red ash); leaflets 7 to 9 pairs and 1, elliptic, acuminate, nearly entire, very long; petioles and young branches downy. It furnishes good wood, more reddish than that of the others. *F. juglandifolia* (*viridis*, swamp ash); leaves very large, leaflets 4 pairs and 1, petiolate, ovate, serrate, glaucous beneath, pubescent on veins; a small tree. Michaux and Nuttall describe 7 more species and some varieties, among which *F. quadrangulata* (blue ash), of Tennessee and Kentucky, attaining 70 feet in height, with valuable wood, and *F. Oregona*, attaining 80 feet, are the most remarkable. In Europe the principal species is *F. excelsior* (common ash), attaining 90 feet, with excellent wood, though inferior to the *Americana*. On its leaves swarm *cantharides* (Spanish flies), spreading a disagreeable smell. A variety with drooping branches (weeping ash) is grafted on tall stems, and converted into an arbor shading all around. II. *Ornus* (Gr. *ὄρνυς*, mountainous) of Persoon (*fraxinus ornus*, Linn., flowering ash), of the same family with *fraxinus*,

Mountain Ash.

but of the class *diandria monogynia*, Linn. Calyx 4-parted; corolla 2 or 4-parted, segments long, ligulate; stamen inserted, with 2 barren

filaments; stigma emarginate; fruit winged, 1-celled, 1-seeded; leaves opposite, unequally pinnate; flowers in terminal or axillary panicles. It grows in shady woods in Europe, N. Asia, and America. Among the American species, *O. dipetala* and *O. Americana* are most remarkable. In Europe, *O. rotundifolia* exudes the *manna*, a sweet substance which differs from sugar by not fermenting with water and yeast, and serves as a purgative medicine. The best manna is collected in Calabria and Sicily. The lilac and olive can be successfully grafted on the species of *fraxinus* and *ornus*. The cultivated species of *ornus* are often grafted on *fraxinus excelsior*; and as *ornus* grows the more rapidly, a curiously protuberant stem is formed, and may by alternate grafting be made to take grotesque shapes. III. *Sorbus* (its bark being supposed to be an absorbent in consumption), of the family *pomaceae*, Juss., *icosandria 2-5 pentagynia*, Linn., classed under the genus *pyrus*. Calyx tubulous, urceolate, limb 5-parted; petals roundish; styles 2 to 5; drupe closed, 5-celled, with cartilaginous putamen; cells 2-seeded. The species are: *P.* or *S. Americana* (mountain ash); leaves

Oak-leaved Mountain Ash.

pinnatifid; leaflets oblong, lanceolate, acuminate, somewhat serrate; common petiole very smooth; flowers white, in terminal corymbs; fruit globose, yellowish red, persistent almost all winter. It grows in Canada and the northern states. *P. microcarpa* (small-fruited) extends from New York into Carolina; smaller than the preceding; fruit scarlet. *S. aucuparia* (rowan tree), common in the forests of N. Europe; grows up to 25 feet; fruit edible, after being frost-bitten and kept in hay for some time. The fruit of other species also affords food to many birds. Only one species (on the Sandwich islands) is known in the tropical regions. The fruits of many contain malic acid, and the flowers, bark, and root of *aucuparia* yield hydrocyanic (prussic) acid.

The wood is valuable for many uses, and the branches were employed by the Druids in their rites. IV. *Xanthoxylum* (Gr. *ξανθός*, yellow, and *ξύλον*, wood), of the family *xanthoxylaceæ*, Juss., *diavicia pentandria*, Linn. *X. Carolinianum* (prickly ash, toothache tree), a middle-sized tree with prickly branches. *X. macrophyllon* (*pterota*, bastard ironwood), in Arkansas and Florida; from 15 to 20 feet high. This species, as well as others (called yellow wood, satin wood, &c.) of much greater size, have hard, cross-grained wood.

ASH, John, an English Baptist divine, born in 1724, died in 1779. He was pastor of a congregation at Pershore, in Worcestershire, and published "A New and Complete English Dictionary" (2 vols. 8vo., London, 1775).

ASHANTEE, the most notable of the existing savage kingdoms on the W. coast of Africa. Its boundaries are not accurately defined; but approximately the kingdom may be considered the region fronting the Gold Coast, between lat. 5° and 10° N. and lon. 1° and 6° W. Until the commencement of the present century Ashantee was unheard of by Europeans, for the Fantees, a hostile tribe, occupied the coast. In 1807 Osai Tutu was king of Ashantee. He appears to have subjugated many of the neighboring tribes. Two of his tributary chiefs having fled to the Fantee country, Osai demanded that they should be given up to him. The demand was refused, and the Ashantee messengers were put to death. Osai thereupon made an incursion into the Fantee country, which he ravaged down to the coast. The British, who had a fort at Anamboe on the coast, undertook to shelter the flying Fantees. The Ashantees invested the fort and compelled the British governor to ask for peace. This peace was of brief duration. In 1817 the Ashantees again invaded the Fantee country, and took possession of it, their acquisition by right of conquest being recognized by the British governor of the fort. In 1823 the Fantees, encouraged by the British, rose against the Ashantees, who again marched into their country. Sir Charles McCarthy, the British governor of the Gold Coast, undertook to chastise the invaders. A sharp action took place, Jan. 21, 1824, in which the British were defeated, the commander and nearly all his officers being killed. The victorious Ashantees came near capturing the British stronghold of Cape Coast Castle; but sickness coming on, they were obliged to withdraw to their own country. Since that time the Ashantees have kept aloof from the seaboard, but appear to have extended their dominion into the interior. Now and then travellers have made their way to Koomassie, the Ashantee capital, in lat. 6° 51' N., lon. 2° 16' W. They report that the government is an absolute despotism. The king is the great property owner, and is the legal heir of all his subjects. Slavery exists on a large scale, many of the nobles having as many as 1,000 slaves. Up to within a few years the

slave trade prospered and gave a large income to the masters; but now that the trade has declined, slavery seems likely to die out. Polygamy may be considered the special institution of Ashantee. The importance of a man is measured by the number of his wives; for these are the cheapest laborers. The king, it is said, is limited to 3,333 wives, who during the working season are scattered over his plantations. While at home in the capital they occupy two streets, where they are secluded from all but the king and his female relatives; any other person who looks upon one of them, even by accident, is punished by death. As to their religion, human sacrifices seem to constitute the distinguishing feature. The soil is fertile, producing every kind of tropical grains and fruits. The abundance of gold displayed as ornaments shows that mines are common; many of the richest, however, are held sacred to the divinities, and so not worked. Among the special industries may be mentioned a beautiful fabric of cotton, woven in strips four inches wide, and afterward sewn together. A considerable commerce is carried on between Koomassie and Hoossa, Bornoo, Timbuctoo, and other points in the interior; the principal exports are gold dust and ivory. The population is estimated to reach, or even to exceed, 3,000,000. (See GOLD COAST.)

ASHBURTON, Alexander Baring, baron, an English merchant and statesman, born Oct. 27, 1774, died May 13, 1848. He was the second son of Sir Francis Baring, who sent him to the United States, where he married in 1798 the eldest daughter of William Bingham of Philadelphia. After his return to England, he published in 1808 a pamphlet relating to the orders in council and to the conduct of Great Britain toward the neutral commerce of America, which passed through several editions. From a partner he became on the death of his father in 1810 the head of the house of Baring, and was a member of parliament from 1812 to 1835, when, after having been for four months president of the board of trade and master of the mint, he was raised to the peerage under the title of Baron Ashburton, which had become extinct in 1823 on the death of his first cousin. (See DUNNING, JOHN.) In the house of commons he had opposed the reform bill, and in the house of lords he opposed the repeal of the corn laws. The unsettled condition of the northeastern boundary question led Sir Robert Peel to send him on a special mission to the United States, where he concluded, Aug. 9, 1842, the so-called "Ashburton treaty." It was assailed by the opposition in England, led by Lord Palmerston, as the "Ashburton capitulation;" and in the United States, Mr. Webster was charged with having been overreached; but public opinion on both sides of the water has sanctioned it as a satisfactory adjustment of difficult matters of controversy, some of which had embarrassed the relations of the two countries for 60 years.

The extraordinary compliment of a vote of thanks for a diplomatic achievement was paid to Lord Ashburton, on the motion of Mr. Hume in the house of commons, and of Lord Brougham in the house of lords; and an earldom was offered to him, which he declined. The negotiations were facilitated by his high character and intelligence, by his amiable disposition, and by his excellent personal relations with Daniel Webster, then secretary of state, one of whose grandsons was named after him. Lord Ashburton was a privy councillor, a trustee of the British museum, and D. C. L. of Oxford. Talleyrand at one time confided to him the custody of his memoirs, and presented him with Canova's bust of Napoleon. He died at the country seat of his daughter Harriet, the widow of the marquis of Bath. His wife, who was a woman of superior accomplishments, died about six months after him.—His eldest son, WILLIAM BINGHAM BARING, Lord Ashburton, who was a member of parliament for 17 years and held various official positions, died March 23, 1864; and his brother FRANCIS, the 3d baron, died Sept. 6, 1868. The present and 4th baron, ALEXANDER HUGH BARING, is the son of the latter.

ASHBY DE LA ZOUCH, a market town of Leicestershire, England, 15½ m. N. W. of Leicester; pop. 3,800. It is a place of resort for its salt-water baths, and has an ancient church and the remains of a fine castle, in which Mary queen of Scots was once imprisoned.

ASHDOD (the *Azotus* of the Greeks and Romans; now called *Esdud*), one of the five chief Philistine cities on the Mediterranean coast, lying midway between Ascalon and Ekron, about 10 miles from each. It is 21 m. S. of Jaffa, and 32 W. of Jerusalem. Its Hebrew name signifies a stronghold, and as it lay in the only practicable route between Egypt and Assyria, its possession was of great importance in all the wars between those powers. The Hebrews were never able to hold it for more than a brief period. About 715 B. C. it was taken by the Assyrians, and 85 years later was retaken by the Egyptians, after a siege by Psammetichus which Herodotus states to have lasted 29 years. It remained a place of some consequence 1,000 years more, for Azotus was the seat of a bishopric, the incumbent of which had a place at the councils of Nice and Chalcedon. In the time of Jerome, about A. D. 400, it was a small unwall'd town. Travellers of the last century describe it as an inhabited site, marked by ancient ruins, such as broken arches and partly buried fragments of marble columns, with what appears to be an ancient khan, the principal chamber of which has been used as a Christian church. This ruined khan, to the west of the present village, marks the site of

the acropolis of the ancient town, and the grove near it alone protects the site from the shifting sand of the adjoining plain, which threatens to overwhelm the spot.

ASHE, a N. W. county of North Carolina, bordering on Virginia and Tennessee, bounded E. and S. E. by New river; area, about 300 sq. m.; pop. in 1870, 9,573, of whom 582 were colored. It is a mountainous region, with portions good for grazing, but is generally not fertile. In 1870 the county produced 16,341 bushels of wheat, 32,311 of rye, 120,545 of Indian corn, 42,350 of oats, and 23,211 lbs. of wool. Capital, Jefferson.

ASHE, John, an officer in the war of the American revolution, born in England in 1721, died in North Carolina in October, 1781. He was six years old when his father emigrated to America and took up his abode in Newton, now Wilmington, N. C. He was several times a representative in the colonial assembly, of which body he was speaker from 1762 to 1765, and is said to have been the first to suggest the provincial congress, in which he occupied a prominent position. He joined the army at the first outbreak of hostilities, led a force to destroy Fort Johnson in 1775, and as brigadier general took part in the movements of Lincoln on the Savannah in 1778 and 1779. In the latter year he suffered a severe defeat at the hands of Gen. Prevost, at Brier Creek. He was made a prisoner in 1781, but was released on parole.

ASHER, the eighth of the sons of Jacob, and the second by Zilpah, the handmaid of Leah. The name signifies "happy." The tribe of Asher at the exodus numbered 41,500 males over 20 years of age, being exclusive of Levi the ninth in order of number, Ephraim, Manasseh, and Benjamin only being below it. Before entering Canaan, the numbers of the tribe had increased to 53,400, making it the fifth. The territory allotted to the tribe of Asher was on the seashore, from Carmel northward, with Manasseh on the S., Zebulon and Issachar on the S. E., Naphtali on the E., and Syria on the N. Its assigned N. boundary on the seashore was a little N. of Sidon; but the Asherites were unable to expel the Sidonians and the other Phœnicians within their limits, with whom they appear to have lived on friendly terms. Their territory contained some of the most fertile portions of Palestine, including a part of the great valley of Esdraelon. Asher and Simeon were the only tribes W. of the Jordan which furnished no judge or hero to Israel. In the time of David the tribe had become so insignificant that it is omitted from the list of the chief rulers; and in the time of Hezekiah it is mentioned with a kind of surprise that some from the tribe of Asher came up to the passover at Jerusalem.
